There is then existing in striated muscle as an original property, *elasticity*, by virtue of which, when stretched, it restores itself to its normal length. There is also *extensibility*, by virtue of which the striated muscle has the property of being extended or stretched. These phenomena can be demonstrated beyond all doubt, although in some muscles they present themselves only to a slight extent.

In addition, striated muscles possess two or three peculiar characteristics. The first of these is *tonicity*. By the tonicity of a muscle, is meant that property by virtue of which it has a constant tendency to contract. When we make section through living muscles, as in amputations, they immediately retract and remain retracted. This is due to the tonicity of the muscles. If paralysis occurs upon one side of the face, the muscles upon the opposite side, by virtue of their tonicity, draw the face, producing distortion. The balancing effect produced by the action of two opposed sets of muscles depends upon tonicity.

Another property is muscular *irritability* or *contractility*. By the term irritability, in its general sense, we refer to the property by which any tissue or organ responds to the action of a stimulus. By response to a stimulus applied to a muscle we have contraction; and the contraction is due to the stimulus applied *directly* to the muscle, or else to the nerves which supply the muscle. There are contractions produced by various kinds of stimuli, but if we examine these in succession, we shall see that the general effect produced is about the same. For the purpose of demonstration, I will take this frog, break up the medulla oblongata, then decapitate, for convenience break up the spinal cord to prevent reflex action, and make the ordinary muscle and nerve preparation.* I will apply to the muscle and nerve the various kinds of stimuli. First, as I pinch the nerve, a contraction of the muscles takes place. This is a mechanical stimulus applied to the nerve by means of which a contraction of the muscles follows. Next I pinch the muscle,† and then a contraction follows, but not so violent as that caused by pinching the nerve. I will make use of another form of stimulation, viz., chemical. For this I will employ a strong watery solution of salt. When I dip the extremity of the nerve into this solution, you see that contraction of the muscles immediately follows. Heat can be employed with the

same results, viz., contraction of the muscles. It is a question of some importance to determine whether or not the muscle depends upon the nerve for its contraction, or whether there is residing in the muscle itself a power by means of which, having received a stimulation, it will respond by a contraction. We shall study this a little further on. In the next place I will apply the electrical stimulus, using the constant current.* As a feeble current is applied to the nerve, you observe the most marked contraction yet seen. When the constant current, therefore, is applied to the nerve, contractions are produced in the muscles to which the nerve is distributed. If now you observe the effect produced as a current is passed through the muscle itself, you will see the same contraction, only not so well marked as when applied to the nerve. I now prepare a fresh muscle† with nerve attached and place it in an apparatus by means of which I can record upon a moving cylindrical surface all the phenomena attending contraction and relaxation.

If for a moment you will recall the fact that, in the gastrocnemius of the frog the time required, after the application of a stimulus, for the completion of a contraction and relaxation, is less than one-third of a second, you can see that it is impossible to detect, by the eye alone, all the phenomena produced. I therefore resort to what is known as the *graphic method*, to assist in determining the changes that occur in the muscle during its contraction and relaxation. In this manner I have recorded in the most accurate way possible every motion that has taken place during the contraction of the muscle.‡

While these contractions are being recorded, I will refer to some other phenomena presented by muscular movement or contraction.

When a muscle contracts it becomes *shorter* and *thicker*. It shortens about one-tenth its original length, and we may know that it becomes thicker and harder if we will observe what takes place, for instance when we contract the biceps of the arm. Now, what are the exact phenomena produced by the contraction of a muscle? This was once a very difficult question to answer, but we can now answer it very well, since we have a more perfect knowledge of the anatomy of the fibre, and the opportunity of studying the phenomena by means of the graphic method. When the muscle contracts, it shortens and hardens; but in its shortening and hardening does not change in volume. What we notice, if we examine under the microscope a single fibre which is contracting, is this, the striations during

* The battery employed was a 40-cell Trouvé, very small elements—only a few cells made use of in this experiment.

† A preparation consisting of the lower part of the femur with the gastrocnemius attached, also the nerve supplying the muscle, was made so as to allow a hook to be fastened in the tendo Achillis. The femur being placed in the clamp of the *myographion*, is firmly secured, and a fine wire attached to the hook in the tendo, passes down to a *tambour* constructed on Marey's plan as adopted quite recently. A bell-glass covers the whole chamber in which the nerve-muscle preparation is contained, and by means of wet sponges laid upon the floor of the chamber the atmosphere is kept moist, which prevents both muscle and nerve from becoming dry, and in this manner a long series of observations may be made. By means of a second tambour, the slightest movement of the muscle is recorded with a very delicate writing lever upon Secretan's cylinder, which revolves with the greatest accuracy once in one minute, or once in ten seconds, or once in one second, as may be desired. The cylinder is covered with white glazed paper smoked with a tallow candle, so that the writing lever marks a white line with very little friction. The tracings are fixed by running the paper, when removed from the cylinder, through varnish, and then hanging up to dry.

‡ The apparatus was then arranged to produce an *imbricated tracing*, according to Marey's latest method. The imbricated tracing is obtained by means of a car moved by clock-work which carries the writing lever along the cylinder, so that a spiral would be traced if the muscular contraction did not occur. The muscle is caused to contract by means of the galvanic current being allowed to break into the nerve (or muscle) at stated intervals, which is accomplished by means of special apparatus.

* This was done by amputating the leg at the hip, exposing and isolating the nerve, and then cutting away the greater part of the muscles of hip and thigh, leaving the femur and rest of the leg.

† Gastrocnemius.

the contractions of the muscle approximate each other, so much so that the ordinary dark spaces seen on the fibre at rest, appear like a series of dark lines, and just at the point where these lines are brought close together the muscular fibre swells; there is a wave which travels in this way quite rapidly throughout the fibre. The wave moves at about the rate of forty inches in a second. Much depends upon how many fibres have

fibre at once. This undoubtedly is to be explained in the following manner. When a single muscular fibre is stimulated a contraction is produced, and a single wave transmitted, but when the nerve is excited, the stimulation is carried to the muscular fibres themselves through a series of nerve filaments, several of which terminate in each muscular fibre, and the effect is the same as if a large number of stimuli were applied to

FIG. 1.

FIG. 2.

been stimulated, for if we excite the muscle itself it will be found that the whole of it is not in a state of contraction at the same time, but that the wave of muscular contraction passes along at about the rate indicated. If, however, we stimulate the nerve, we find that the muscle has, as it were, a contraction of every

the muscular fibre at different points on each fibre, at one and the same time. In this manner the whole muscle is thrown into contraction at about the same instant. A certain length of time elapses between the application of the stimulus and the development of the response, which can be calculated. This is what

FIG. 3.

is called the *latent period*, or the period previous to the occurrence of the contraction, and will be described further on.

What we have studied to-day, then, may be summarized as follows:

There are movements in the body which may be classed under two general heads, passive and active. Besides, we have what are known as protoplasmic and ciliary movements. Under the head of passive movements are those produced by the elasticity of certain connective tissues, and these are exhibited principally in connection with muscular contractions, restoring the parts to their original position. We refer, under the head of muscular contraction, to the striated or voluntary variety.

These muscles possess certain properties.

First, *irritability*, by virtue of which they respond to the influence of stimuli and contract.

Second, *tonicity*, by virtue of which they are in a constant state of passive contraction.

There remain the hardening and shortening with thickening without change in volume; *elasticity*, by virtue of which they may be stretched and then return to their original length. These muscles also possess the property of *extensibility*, by virtue of which they are able to stretch when weighted, but having reached a certain point, extensibility diminishes out of proportion to the increment in weight.

From the tracings obtained, it will be seen that the muscular contraction takes place in the following manner, viz.: the contraction is rapid and sudden, reaching its maximum instantly (as shown by the nearly perpendicular lines in the figures). The relaxation follows immediately, and is comparatively slow (as the curved lines designate). One-third of a second represents about the time occupied for both contraction and relaxation.

Fig. 1 gives a very good idea of the individual contraction and relaxation, as the tracings are separated somewhat.

Figs. 2 and 3 are imbrications, arranged nearer to each other, so that the effect of continued irritation may be observed.

Original Communications.

ON IODOFORM AS A REMEDY IN THE TREATMENT OF AFFECTIONS OF THE CORNEA AND CONJUNCTIVA.

By CHARLES S. BULL, M.D.,

OPHTHALMIC SURGEON TO CHARITY HOSPITAL, ASSISTANT SURGEON TO THE N. Y. EYE INFIRMARY, MICROSCOPIST TO THE MANHATTAN EYE AND EAR HOSPITAL.

ABOUT a year ago the attention of the writer was called to the therapeutic value of iodoform as a local application in cases of pannus and phlyctenular keratitis, by Dr. Edward Curtis, of this city, and since that time the writer has used it in a large number of cases with very beneficial results. At first I employed it empirically, or at least attributed to it only an anæsthetic action; but being somewhat surprised at the effects produced, I have studied its action more carefully. In the first case in which it was employed, which was a woman with a sluggish keratitis marginalis, with small phlyctenule on the edge of the cornea, and an obstinate form of marginal blepharitis, the patient came the next day and said the eyes felt very much better; there was scarcely any lachrymation, and the feeling of irritation and the photophobia had almost disappeared. The application was continued daily, and the improvement continued. I now began its use systematically in the class of cases just mentioned, and was almost always gratified by a rapid and steady improvement. The results in each case were carefully observed, and thus an attempt was made to discover its mode of action; how the effect was produced, and whether it was due to a purely local action or to a constitutional influence as well.

We know that iodoform, when taken internally, acts as a tonic, a stimulant and an alterative, and exercises a remarkable influence on the nervous system. Its local anæsthetic effect is most marked, and is illustrated by its anodyne influence in cancerous and other ulcers. Though it contains 29 parts in 30 of its

weight of iodine, it has not the least local irritant action. On account of this large proportion of iodine it is supposed by many that it may replace the latter as a remedy, with the advantage of being a non-irritant, and of having an organic nature, qualities which would promote its absorption and assimilation. Now, if, in addition to using the drug locally, we determine to administer it internally, we must endeavor to explain, 1st, What is the ultimate effect of its action on the system; 2d, In what way does it operate; and 3d, To what organ or tissue is its action directed.

Now we know that iodine acts neither by eliminating, nor by stimulating, nor by depressing, when taken internally, but appears to counteract in the blood the agency of certain morbid poisons, and is thus really an alterative. It tends especially to affect the blood and blood-making organs, rather than the nerve-tissues. When we apply iodoform in substance locally to the eye, we must decide how it acts, whether by mere contact; its influence being propagated to more distant parts by means of the nerves; or by passage thence into the system through the medium of the blood-vessels and lymphatics. Now, in laying down the rule of the necessity of local access for the production of the primary effect of a medicine, we must be careful to remember that no proper medicinal action can be conducted along a nerve fibre, for it has long been known that vascular connection is necessary for the propagation of constitutional effects.

There are quite a number of medicines in our pharmacopœia which have a marked local action on mucous membranes, and among these we must place iodoform, owing to its well-known properties as a local anæsthetic, whether as a vapor or in substance. Continued observation of the results of iodoform in certain cases have convinced me that the beneficial effect is mainly owing to the local action of the drug as an anæsthetic, but I also believe that it exerts an alterative action in the system, through absorption by blood-vessels.

The first noticeable sign of its action after being dusted upon the cornea and into the cul-de-sac is rather a negative one, in that it causes no irritation at all, or at least a very slight one, and this in but very few cases. This is rather remarkable when we consider that iodoform in substance is crystalline in structure, each crystal having very sharp angles. Perhaps its non-irritating character is due to its being entirely devoid of corrosive properties.

Another sign of its beneficial effect is the cessation of the pain and photophobia in cases of pannus and obstinate ulcer of the cornea, where these symptoms are often very troublesome. The pain often ceases after the first application, and the photophobia also disappears within a day or two. May we not explain the disappearance of both these symptoms as due to the anodyne action of the drug? In some of these cases of pannus and phlyctenular keratitis, the sensitiveness of the cornea and conjunctiva is very greatly increased. The terminal nerve twigs grow into the new inflammatory tissue, and as they generally are very superficial, are consequently exposed to the constant secretion of a pannus accompanied by granular lids, or to atmospheric influences, or to both, particularly if the cleansing of the eyes is frequently repeated. Atropine, though it may dilate the pupil, often fails in quelling the pain. Now the iodoform comes into immediate contact with the exposed nerve-fibres, and produces within a very short space of time complete anæsthesia of the parts, and if the action is kept up long enough, and is frequently repeated, the anodyne effect extends more deeply into the inflamed tissues.

In most of the cases I kept up the use of caustics to the lids as usual, where there was any hypertrophy of the palpebral conjunctiva in connection with the pannus, but having found that the iodoform worked very well alone, I discontinued the use of the caustics in all cases except where there was real trachoma or granular lids, and have been very well satisfied with the results. Of course in the latter class of cases, caustics must be regarded as absolutely indispensable, and the iodoform can only be looked upon as an adjuvant in the treatment.

Most of these cases of pannus and phlyctenular keratitis occur in persons of a strumous diathesis, and whether this has anything special to do with the beneficial effects of the local action of the drug, is a question not yet satisfactorily settled in my own mind. Owing to the large amount of iodine it contains it might be thought that enough was absorbed by the vessels of the conjunctiva to exert a specific action upon a strumous constitution. But it is still somewhat doubtful whether the lachrymal or conjunctival secretion contains any ingredient which will dissolve the iodoform, and thus facilitate its absorption, for it is insoluble in water.

In these cases of pannus and keratitis, dependent on a strumous diathesis, though there is nothing unique or characteristic about them, yet we almost always administer internally some form of iodine in combination with tonics, in addition to the local treatment, and the syrup of the iodine of iron is always a favorite remedy; but of late I have been giving iodoform internally to these patients in doses varying from half a grain to two grains, in combination with the citrate of iron and quinine, three times a day, according to the age of the patient, and with very excellent results. The cure of the pannus or keratitis is hastened, and a very beneficial effect is produced upon the general tone of the system. It seemed to facilitate the absorptive process in enlarged glands, and thus certainly acted as an alterative.

I have never noticed any ill effects from its local or internal administration, even when its use has been continued for weeks, and with children its internal administration seemed to be borne better than the syrup of the iodide of iron. Of course, after some weeks the system becomes almost saturated with it, although some of it must be carried off by the urine, but a great deal is given off in the pulmonary exhalations, and the patient's breath has a very perceptible odor of iodoform. How long this will last after the administration of the drug has been discontinued, I do not know, as the cases almost always disappeared from observation, when the severity of the symptoms subsided. M. Maître affirms that iodine can be detected in the saliva and urine, two hours after iodoform has been administered, and that nearly three days elapse before the whole is eliminated. He states that from a dose of thirty or forty centigrammes, no effects are observed except a slight increase of the appetite. In large doses the drug acts as a narcotic and has two stages: the first stage is one of more or less prostration, with symptoms of intoxication followed by complete recovery. If still a larger dose is given, the second stage comes on, and is marked by intense excitement, anxious breathing, a strong and bounding pulse, opisthotonos, and death.

Iznard uses iodoform in solution as a local application, and recommends the following formula:

R. Iodoformi	grammes 2-3.
Glycerinæ	grammes 30.
Alcohol	grammes 10.

This, however, would probably occasion considerable pain, and hence the drug in substance is to be preferred.

A CONTRIBUTION TO AURAL SURGERY,
WITH A DESCRIPTION OF A NEW
EAR-DRUM.

By BEVERHOUT THOMPSON, M. D.,

VISITING PHYSICIAN TO THE CENTRAL DISPENSARY; ONE OF THE
ATTENDING PHYSICIANS TO THE OUT-DOOR DEPARTMENT,
BELLEVUE; MEMBER OF THE NEW YORK COUNTY
MEDICAL SOCIETY.

HAVING a patient to treat suffering with tubal catarrh, whose membrana tympani had been destroyed by ulceration resulting from otitis media, and whose hearing was so much impaired that the tick of a watch could only be heard when placed in direct contact with the ear, I attempted to increase the hearing with an artificial ear-drum, but not deriving much, if any, benefit from its use, it occurred to me that I might devise a drum to resemble the natural one more nearly, and which would vibrate to better advantage. After several ineffectual attempts, I succeeded in constructing a drum that accomplished the purpose much better than I anticipated, and increased the hearing distance of my patient three to four inches.

In order that the advantages of the drum which I offer to the notice of the profession may be appreciated, I will refer to the physiological uses of the membrana tympani, describe the drum commonly used, point out its defects, and endeavor to show wherein mine is superior. The waves of sound being collected from various directions by the external ear, and conveyed to the meatus externus, are concentrated upon the tympanum, striking the membrane, vibrations take place, and are transmitted by the chain of bones to the labyrinth and auditory nerves. Now if the membrane is thickened, perforated, or destroyed, hearing is more or less impaired, owing to the want of a vibrating surface for the reception of the waves of sound.

The ordinary drum is composed of a thin piece of flat round rubber, pierced in the centre with a small wire pin, which is riveted on both sides to prevent slipping; the rubber is cut with scissors to fit, and is introduced by the wire pin to its proper position. The objections to this drum are—it is made of rubber, which, owing to its elasticity, is not a good vibrating substance, is much thicker than the natural drum, is perforated in the centre with a wire pin which often pulls out, and is not tense enough. All of these imperfections have been overcome in the drum I have constructed. It has a thin piece of gold-beater's-skin for the membrane, which is about the thickness of the natural membrane, stretched tightly over a ring of silver; the pin by which it is inserted is firmly attached to the side of the ring, and does not in any way interfere with sound or prevent vibration. I took a small silver wire, about five inches in length, such as is sold for sutures, bent it around the end of an ear-speculum, making a single knot, and twisted the two ends together at right angles to the ring for the pin. After fitting the ring, which was made oval to suit the meatus where the drum rests, I wetted the gold-beater's-skin, stretched it tightly over the ring and tied it with fine silk, which when dry was sufficiently tense.

I here give a sketch of the drum as it should be made by an instrument-maker, which consists of a thin ring of silver; E, over which the gold-beater's-skin is stretched; C represents a small rim of silver which fits

over the ring and secures the skin; D, the pin by which it is introduced is fastened to the side of the ring, and can be bent in any form to suit the curve of the meatus

and facilitate introduction. By having the frames of different sizes it is easy for the surgeon to select one to suit, and stretch the gold-beater's-skin over it, or the size may be accurately taken with a piece of silver wire as explained above, and sent to the instrument maker, who will shape a frame, and adjust the gold-beater's skin.

Progress of Medical Science.

HEMORRHAGIC INFARCTION OF THE LUNGS.—Dr. Gerald F. Yeo, of Dublin, recently read a paper on the anatomical changes found in the lungs in cases of cardiac hemoptysis, where the lesion was formerly described by Laennec, as pulmonary apoplexy, but for which the name hemorrhagic infarction has more recently been substituted. A few days after their appearance the lesions appear as isolated spots of intense engorgement, in diameter varying from one to ten centimetres, and scattered through the lungs in irregular positions, as many as three or four being frequently found. They are extremely hard, almost quite black, and perfectly airless, one of their most striking characters being their sharp demarcation from the surrounding lung tissue, which remains healthy and retracts so as to allow the hard nodules to stand out prominently. These are very constantly conical in shape, the apex of the cone being directed towards the root of the lung, and the base towards the surface, where it shows as a circular knob. Their section is finely granular and even, the vessels in the cone enter it at its apex, and are always plugged with adherent fibrinous clots. The bronchi are empty, or contain bloody mucus. The clinical history is often obscure; sudden local pain, with dyspnoea, followed, in a few hours by more or less profuse hemorrhage, with the existence of old heart disease, are the chief indications that the infarction has taken place.

The area of condensation is commonly too small, and its position too variable to produce any very characteristic physical signs. The common explanation given since the time of Laennec, was that the hemorrhage was due to rupture of the pulmonary capillaries by means of an abnormally strong right heart. Virchow showed that a free body or embolus in the circulation must become impacted in some vessel, and there set up changes which depend on the character of the substance, the freedom of arterial anastomosis, and the efficiency of the venous valves of the part.

Simple œdema, inflammation, gangrene, abscess, atrophy, and not uncommonly infarction, simple or hemorrhagic, followed the occlusion of a vessel by such a plug.

Cohnheim confirmed Virchow's theory, and described the various steps in the process, as seen under the microscope, to be successively dilatation of the vessels; to-and-fro movements in the blood; œdema and

emigration; hemorrhage; and finally stasis. The emboli causing infarction in heart disease are readily supplied from the little clots so commonly formed where the blood current is retarded among the trabecule in a dilated right ventricle, or in the auricular appendix. Dr. Yeo also mentioned disease of the pulmonary vessels and hypertrophy of the right side of the heart, as influencing the amount of hemorrhage. The changes in the right heart are usually secondary to disease in the left, and in the transmission of the injury back through the lungs the vessels must suffer. One or both these are essential to the extensive hemorrhage which proves so often fatal. According to Dr. Yeo, the probable chronological sequence of events might be thus enumerated: 1. Prolonged impediment to pulmonary circulation. 2. Injury to the pulmonary vessels. 3. Dilatation and hypertrophy of right heart. 4. Production of cardiac thrombi. 5. Separation of portion of clot. 6. Impaction of embolus in pulmonary artery. 7. Infarction, with more or less bleeding.—*Irish Hosp. Gazette*, March 1, 1875.

AXIOMS ON LITHOTRITY.—Dr. Ivánchich, of Vienna, has published a list of 234 cases in which he has practised lithotripsy, and he now lays down certain axioms for the guidance of the operator, though he states that these axioms are merely repetitions of those that he published more than thirty years ago, when his views were based on only a few dozen cases. They may be stated in brief as follows:

1. Lithotripsy before the twelfth year is only exceptionally and very rarely indicated.
2. Sex as sex is no contraindication to it. He adds, that in girls under twelve years, the operation offers rather better results than in boys.
3. From the twelfth year on to old age the chances of a successful result increase continuously until old age. In general, lithotripsy has a decided advantage over lithotomy. Crushing should always be regarded as the general method, and cutting the exceptional one.
4. While organic and functional integrity of the genito-urinary organs gives hopes of a successful issue in lithotripsy, yet a very marked deviation from this condition is not an absolute contraindication. Phymosis is relieved by division or circumcision; strictures of the urethra by appropriate preliminary procedures; hypertrophy of the prostate, especially of its middle lobe, often presents a fatal barrier, but it is often not insurmountable. The spontaneous discharge of the fragments, which is hindered by this latter condition or by paralysis of the bladder, can be compensated for by their artificial extraction. Symptomatic or intensive catarrh of the bladder, whether the urine be acid, alkaline, or neutral, has of itself but little influence on the question of this operation. On the other hand, increased sensibility of the urinary passages is a matter of great moment in lithotripsy. The introduction of anæsthetics has, however, caused this latter condition to be no longer a contraindication to the operation. Profound organic lesions of the kidneys, ureters and bladder, when they can be diagnosed, are a bar to lithotripsy, but they also make the issue of lithotomy questionable.
5. Lithotripsy is favorable for one or more stones, when they are not larger than a walnut, and especially when they are not very hard. The chemical composition of such stones has little to do with the question, even if the stone be oxalate of lime. But stones the size of a hen's egg, even when they are hard, are not always refractory to lithotripsy. In this connection the author alludes to case No. 20 in his list, where two uric acid calculi, weighing together somewhat over four ounces, English measure, were successfully removed at fifteen

sittings. Yet the size of the stone, especially when added to other complications, is often a contraindication to the operation. Such cases will always give rise to the most delicate questions, and the solution of them will depend on the penetration of the surgeon. Stones that rest in diverticles of the bladder, and those which are lodged in the neck and cannot readily be pushed back into the bladder, must be removed by lithotomy, as must all calculi that have voluminous non-friable bodies as nuclei. 6. In conclusion, it is stated that invariable determinate indications and contraindications for lithotripsy cannot be laid down on paper, and that in doubtful cases it will depend on the practical tact of the surgeon to decide whether the operation is to be done at all, and which one, or whether merely a palliative procedure is to be adopted. The result of the operation will often be the only means of deciding whether the indication has been rightly or wrongly interpreted.—*Allg. Wien. Med. Ztg.*, 1, 1875.

THE ETIOLOGY OF PUERPERAL FEVER.—Dr. Robert E. Huntley, of Jarrow-on-Tyne, in an interesting article on the above subject, makes the following remarks. It is of vital import that the obstetrician should recognize at the very earliest stage the true character of the malady; and the points to which, in his opinion, attention ought to be directed, are the various causes from which puerperal fevers originate. These may be divided into three classes.

1. Those originating in the patient, as general ill health giving rise to inflammation of the uterine and peritoneal structures, or such as spring from intra-uterine causes, putrescence of the infant, or of the other contents of the uterus.

2. Such as spring from atmospheric influences, and give rise under ordinary circumstances to fevers, as scarlatina, typhoid, and typhus.

3. That lamentable and malignant form mysteriously communicated by the accoucheur.—*British Medical Journal*, Feb. 27, 1875.

THE ENDEMIC FEVER OF JERUSALEM, AND ITS ETIOLOGY.—Dr. Loudon, during an eight years' stay in Palestine, in a professional capacity, had a good opportunity of observing the diseases of that region. He states that the prevailing disease at all seasons of the year in Jerusalem is fever of the varieties intermittent, remittent, and pernicious. He attributes their occurrence to the cistern-water in common use. This is collected principally in the winter, and in the course of the summer becomes exceedingly foul and full of organic impurities from standing so long in the imperfect and filthy cisterns. To fifty patients suffering from intermittent, he gave quinine in large doses, but at the same time allowed them to drink the ordinary cistern-water. To another fifty he gave no quinine, but simply took pains to have them supplied with drinking-water brought from a well two miles distant from the city. The latter promptly recovered from their intermittent, while the former fifty either did not get rid of it, or had frequent relapses. The cases of fever are much less numerous during winter, when the water is fresh. Dr. Loudon also believes, that the dysentery and cholera, which likewise prevail, are referable largely to the same cause. He found that these cases were benefited by quinine.—*Report of the Session of the Gesell. der Aerzte zu Wien*, in *Allg. Med. Cent.-Zeit.*, March 13, 1875.

THE SO-CALLED THIRD DENTITION.—Dr. Scheff holds the opinion that teeth of this class consist of those that are delayed in their appearance from various causes, which he enumerates as follows:—1. There may be an abnormal formation of bone in the socket

of the milk-tooth, thus preventing the extrusion of its successor until an advanced period of life, when the alveola has become atrophied. 2. The tooth-germ may be retarded in its development from insufficient nutrition, a fact which he states may be proved of such teeth by the microscope. 3. The growth of the jaw necessary to afford room for the teeth may be prevented, thus causing too short a dental arch.

These teeth, when extracted from patients in later life, are always the eye-teeth, which is natural, as they come last in the order of succession in second dentition, the first being the central incisors, the second the lateral incisors, then the first molar, and finally, the eye-teeth. The time at which all the teeth appear thus in late life is only when there is a complete atrophy of the alveolar process, and the gum has retracted more and more until it lies immediately upon the jaw. It is noticeable that such teeth are defective, perhaps carious, and never supply the lack of real teeth, but give rise to annoyance and have to be extracted.—*Kundschau*, Feb., 1875.

ABLATION OF NEARLY THE WHOLE SPLEEN, WITH RECOVERY.—The following case has some interest as an additional instance of those rare cases where a large portion of spleen has been successfully removed, and as showing that the operation may be followed by no apparent injury to the general health:

It is reported by Dr. Elias that a young man of eighteen, during a struggle with some companions, was cut in the left hypochondrium in such a way that the spleen protruded through the wound. He ran a mile to the police station, and when received into the hospital was so exhausted that no successful attempts at reduction could be made for four days, and by this time the organ was quite strangulated by the adhesive inflammation which had been set up. He had a pulse of 112 to 120, no appetite, a coated tongue, and some headache. His skin was cool. There was no pain except at the wound, the extent of which was $3\frac{1}{2}$ by $1\frac{1}{4}$ inches. The hilus of the organ could be felt by the finger in the wound. All other operative interference, although strongly indicated, was precluded by the commencement of putrefaction, and a ligature was put around the protruding part close to the thorax, while disinfectants were applied to the injured parts. At the end of three days, as there was fear of purulent absorption, almost the whole organ was removed by the knife, care being taken to avoid the large vessels. A small portion remaining in the wound sloughed off the next day. After suppuration, lasting for from 20 to 25 days, the wound cicatrized. The general condition of the patient improved vastly during his stay in the hospital, and he gained in color, strength, and weight, while all his bodily functions appeared to be well performed.—*Gaz. Méd. d'Orient.—Ally. Med. Central-Ztg.*, March 23, 1875.

ATROPIA AN ANTAGONIST OF JABORANDI.—Drs. Sydney Ringer and Gould having discovered that atropia arrests the salivation and diaphoresis produced by jaborandi, a fact which Vulpian has also observed, the latter has performed experiments to see if atropia has also a similar effect on other secretions increased by jaborandi. He first demonstrated in a very clever manner by means of canule introduced into the canal of Wirsung, ductus choledochus and the ureter, in dogs that were curarized and subjected to artificial respiration, that the pancreatic, biliary and urinary secretions were increased to a very notable degree by the injection of an infusion of jaborandi leaves into the crural vein in the direction towards the

heart; he then observed that the pancreatic secretion was completely arrested a few minutes after the injection of one-third to one-half of a grain of atropia in an aqueous solution.

The biliary and urinary secretions were diminished considerably under the same conditions, but they did not stop altogether. In one of his experiments, where the stomach was opened before the injection of jaborandi (an infusion of a little less than a drachm of the leaves to the ounce of water) he saw a certain quantity of fluid flow from the mucous membrane of the stomach; after observing the fact he shortly afterwards injected a similar infusion of jaborandi, but followed it by an injection of one-third to one-half a grain of atropia, and the appearance already noted did not then take place.—*Gaz. Hebdom.*, 12, 1875.

VARIATIONS IN THE SEAT OF METASTATIC ABSCESSES IN PURULENT AFFECTIONS.—M. Desprès presented his views on this subject before the Academy of Medicine in Paris, at a recent meeting. He based his conclusions on thirty-four cases which he had observed, and in which there had been three cures and thirty autopsies. He stated that metastatic abscesses do not occupy the same organs with regularity. In purulent infection it is as in constitutional syphilis, the lesions have points of predilection, and these vary according to the temperament and habits of the affected persons; he lays down the following three laws:

1. Pulmonary metastasis is the normal law in acute purulent infections in normal cases. Whenever the inflammation or wound that causes infection affects the vessels of the general circulation, metastatic abscesses occupy the lung.

2. Pyæmia, following lesions that affect the venous system of the liver, engenders, normally, metastatic abscesses of the liver.

3. In patients who have suffered from disease previously, or are following a course of life that permits of permanent changes in an organ, metastatic abscesses will have their seat in this organ as well as in the lung. Thus we see metastatic abscesses in the liver in persons addicted to alcoholism, and in the spleen in those who have had intermittent fever.—*Gaz. Méd. de Paris*, 14, 1875.

A NEW POINT IN THE DIAGNOSIS OF OVARIAN DISEASE.—At the Pathological Society, March 16th, Mr. Spencer Wells mentioned a very striking fact in illustration of the practical use of the treatment and prognosis of disease. He has long taught that single cysts near the ovary may be truly ovarian (excessive growth of one Graafian follicle) or extra-ovarian (dilatation and growth of part of the remnants of the Wolffian body, or parovarium), and he has found that, while the extra-ovarian cysts are often radically cured by a single tapping, the cyst contracting and never refilling, the true ovarian single cysts are almost certain to fill again. He had also shown that the contents of the parovarian cysts consisted of little more than pure water, with scarcely any albumen, or only a little albuminate of soda, the specific gravity seldom exceeding 1.005. Mr. Thornton has recently discovered that the fluid in some single ovarian cysts contains little groups of cells, which he believes are only formed from the lining membrane of the Graafian follicle; and the presence of these cells, with the higher specific gravity and the albumen or paralbumen in the fluid, are sufficient to enable the surgeon to say after tapping a single cyst, whether it is likely to be radically cured by tapping only, or whether it is almost certain to refill and regain ovariotomy.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

W.M. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, April 24, 1875.

THE CHEAPNESS OF MEDICAL CERTIFICATES.

It is often a matter of surprise to us to see how ready medical men are to append their names to all sorts of certificates. In the majority of instances this may be explained by a desire to gratify a vanity which certain individuals have in being considered men of reputation and influence, and is one of the ways of covertly advertising themselves in that capacity. In other instances it is the want of the appreciation of the true value of a good name. There are very few of the profession who are not numbered in one or two of these classes. The consequence is, that there is hardly a contrivance or medicinal preparation offered for sale the advertisement for which is not paraded with an appendage of certificates of distinguished men. But we do not stop here. If there is any new washing apparatus, sewing machine, patent ventilator, new whiskey, or, in fact, anything that may, directly or indirectly, have any influence upon the health, the parties interested have no difficulty in getting the signatures of all the "eminent medical men" they may want.

It is very much the same thing with certificates of character. If a young medical man desires a position, either in a hospital, health board, or dispensary, he knows just the prominent medical men upon whom he can call for a good recommendation, and he is never disappointed. In fact, these certificate writers seem to have a set form of indorsement, from which they seldom, if ever, vary; and while they say their best for the meanest applicant, they can do no more for the best. In the matter of recommendations for nurses the same thing is done: a great many of the gentlemen who give these certificates either know little or nothing of the persons they indorse, or else they look upon the affair as a matter of form, with which they often stretch their consciences in complying. The consequence is, that medical certificates have a very indifferent value, as very few have any weight what-

ever. A prominent politician, in canvassing the respective merits of a number of physicians who applied for a medico-political appointment, remarked, that of twenty-five of these applicants, almost all had the same signatures to their appeals, certifying to first-class attainments. He very properly remarked, that all the gentlemen evidently stood so high in their profession that it was impossible to make any choice. It is not fair to assume that the habitual signers of medical certificates are, in the main, actuated by any other than good motives; but we must, nevertheless, admit that their names are fast becoming such cheap commodities, that they will ere long be quoted below even their strictly market value.

Outsiders whose business it is to trade on other men's good name, are not slow to take advantage of this state of affairs. Assuming on general principles that medical men are indifferent upon the subject, they lose no opportunity of turning this indifference to their account. We know of not a few good men who have been inveigled into a tacit approval of some invention or scheme, whose names have been paraded to the public in the most barefaced and defiant manner, and that, too, with no power, seemingly, to prevent it. It is true these gentlemen never dreamed that they were doing anything more than writing a friendly note, in acknowledgment of a present, perhaps, or in recommending an inventor to a professional brother, or the like; but they have since learned that too much care cannot be exercised even in these apparently innocent offices. We believe that these men are heartily sorry for what they have done; but this sorrow can hardly counterbalance the reasonable interpretation of their motives by their professional brethren. We know of one gentleman, whose name, on the slight excuse of a few lines of very equivocal indorsement of a new hygienic scheme, has his name, with all his titles attached, paraded in one of the most public of thoroughfares; while another had a letter of his actually autographed and published broadcast over the country. There are very many similar instances which have come to our knowledge, that prove not only that medical recommendations are quite cheap, but that those who obtain them are by no means scrupulous in their use of them. The conclusion to be drawn from this is, that too much care cannot be exercised in signing anything that may be presented to us, no matter who the individual may be who asks for such a service. If our names are to become the trade-marks for some enterprising manufactory, or some covert quack, we had better sell ourselves out at once and retire.

Pursuing the subject still further, we find that it is fast becoming the fashion to use the names of prominent medical men to endorse nostrums, questionable treatises, etc., without going through with the usual formality of even asking permission. This is now so extensively done to our personal knowledge that it is time to call attention to the fact that, those of our brethren who may not know how or why it is done should exercise

a reasonable charity towards the victims. Not long ago we had placed in our hands a pamphlet which, on its face, was an advertisement for the most shameful kind of quackery, upon the fly-leaves of which were the names of some of the most prominent of our medical men as indorsers, not only to the outrageous doctrines therein contained, but to the preposterous method of treatment advocated. It is absurd to suppose that any of these gentlemen ever saw the writer, or ever heard of his little book. Still, this is done every little while; but because the practice is carried on without the knowledge of the parties interested in the misrepresentation, it should not the less be entitled to a charitable interpretation by the profession.

Reviews and Notices of Books.

CROUP IN ITS RELATIONS TO TRACHEOTOMY. By J. SOLIS COHEN, M.D., Lecturer on Laryngoscopy and Diseases of the Throat and Chest in Jefferson Medical College. Philadelphia: Lindsay & Blakiston, 1874.

"Would that more such books were published," was our sincere wish on finishing the attentive perusal, we may say study, of the work the title of which heads this article. It is a book of only 78 pages, and what most people call not an original book; yet, in our deliberate judgment, the whole medical profession owe Dr. Cohen a debt of gratitude for it which can only be paid by each member doing his part toward making it known to every other member. It contains a conscientious compilation and judicious appreciation of all that could be gathered by the author upon the subject of which it treats; and, so far as knowledge of a practical subject can be acquired by reading, whoever chooses to make these comparatively few pages his own will become *thoroughly posted*.

If we had had the making of the title, we would have put it, Tracheotomy in its relations to Croup, for the operation is the chief subject of the essay, but this is perhaps hypercriticism; at all events it is of small importance, as the contents of the book respond closely enough to the title it bears.

After a few introductory remarks, Dr. Cohen tells us that tracheotomy for croup is generally regarded with much disfavor in Philadelphia. "Its results in Philadelphia have been less encouraging than almost anywhere else; probably because, as a rule, the operation is postponed too long; possibly because our medicinal treatment of croup cures a number of cases which, under less efficient management, would become subjects for tracheotomy: but whatever the cause, the results, in a comparatively few instances in which the operation has been performed, have been so disheartening, that many practitioners refuse to sanction tracheotomy in croup under any circumstances. This radical feeling is wrong. Not only should our individual experience be utilized in judgment, but the recorded experience of others also. Early failures may be followed by ultimate successes."

Some statistics are given to illustrate the last point; and the author continues, "That tracheotomy saves many croup-patients from death otherwise inevitable, and that, too, even under favorable circumstances, there has long been no reason to doubt. There is little doubt, either, that patients are occasionally tracheoto-

mized unnecessarily, but the proportionately small number of such instances, whether errors of judgment or errors of prudence, is in all probability insignificant in comparison with the number of patients saved by the operation from certain death—life being preserved in the one instance, while it is not sacrificed in the other."

"But how are we to estimate the percentage of recoveries in desperate cases without tracheotomy? how estimate the percentage that die for want of tracheotomy? how estimate the number of awkward tracheotomies? how estimate the number of deaths due to the operation itself, or to untoward circumstances which follow it? how estimate the number operated upon when half dead, or in articulo mortis? how separate the causes of death after tracheotomy, whether incident to the disease, to previous exhaustive treatment, to the operation itself, to inefficient after-treatment of the wound or of the disease?"

Statistics of the operation—more than 5,000 cases—are then given from French, Germanic, British, and American sources. The author recognizes that the age of the patient has an important influence on the success of tracheotomy for croup. Very few children under two years are saved; very few over eight or nine, and adults seldom or never. Then, selecting the best individual series of statistics from those already given, a table of results is obtained in remarkable contrast with the entire list. Of this table Dr. Cohen says: "Many fortuitous circumstances may have been combined in these instances to favor better results than have been obtained in other series of operations. A favorable age in the patient, a good selection of cases, a happy recognition of the proper moment for surgical interference, skilful operation, and assiduous after-treatment may have been the causes leading to such excellent results. These are the elements of success; and it is, in a measure, to assist in a better appreciation of these elements of success that the paper has been compiled."

The following main topics are then discussed in succession: I. The indications for the operation. II. The points of importance in connection with the operation itself. III. The after-treatment of the disease and of the surgical wound; and IV. The casualties which prevent recovery. We cannot follow the author in the detailed discussion of these topics, but trust that our readers will procure his book and do so. We desire, however, to call Dr. Cohen's attention to two or three points that he might take into consideration when preparing a second edition, which, we hope, will soon be called for. The directions he gives for making the incision into the trachea leave nothing to be desired; but the possibility of one accident is not alluded to, viz., that of not including the mucous membrane of the front wall in the incision. He cautions the operator against carrying the knife too far, so as to wound the posterior wall, or make a counter-opening into the cesophagus. He also says: "Another untoward complication may arise, in cases where false membrane is present in the path of the knife, by pushing it over against the posterior wall of the trachea;" and mentions that in a number of instances where false membrane existed upon the front wall, the point of the knife did not penetrate the false membrane, but merely loosened it and pressed it backward, occluding the tube, and in this way rendering suffocation imminent; but a case has occurred under our own observation in which the operator, supposing that he had reached the interior of the trachea (especially as air bubbled and whistled through the wound), introduced the canula, pushing uncut mucous membrane before

it, and tearing it from its connection. Secondly, neither in speaking of the different kinds of canula, nor in speaking of the causes of hemorrhage which may occur after the operation, does the author call attention to the danger from fenestrated tubes. Dr. Sayre reported a case to the New York State Medical Society in 1864, in which death was caused by sloughing of the wall of a vein lying on the sharp edges of the openings; and a number of more or less similar cases have occurred in which soft parts bulged into both fenestra, and the intruding portion has been cut off by the removal or reinsertion of the inner tube. Thirdly, he omits mention of the valuable Roser after-treatment canula, which is made on the principle of the wire vaginal speculum for baths.

We reproduce the conclusions which the author himself draws at the end, viz.: I. That there are no insuperable contraindications to tracheotomy in croup. II. That the administration of an anæsthetic for the purpose of controlling the child's movements is admissible in performing the operation; but that it should be used with great caution. III. That a careful dissection should be made down to the windpipe, and hemorrhage be arrested before incising it, whenever there is at all time to do so. IV. That the incision should be made into the trachea as near the cricoid cartilage as possible, to avoid excessive hemorrhage, and subsequent accidents which might occasion emphysema. V. That a dilator should be used, or a piece of the trachea be excised, whenever any difficulty is encountered in introducing the tube. VI. That the tube should be dispensed with as soon as possible, or altogether if the case will admit of it. VII. That assiduous attention should be bestowed upon the after-treatment, especially that of the wound; and that a skilled attendant should be within a moment's call for the first twenty-four or forty-eight hours immediately following the operation.

OUTLINES OF THE SCIENCE AND PRACTICE OF MEDICINE. By WILLIAM AITKEN, M.D., F.R.S., Professor of Pathology in the Army Medical School; corresponding member of the Royal Imperial Society of Physicians of Vienna, etc., etc., etc. London: Charles Griffin and Company, 10 Stationers' Hall Court, Philadelphia: J. B. Lippincott & Co. 1874.

This book contains 580 pages of reading matter, and is merely a compendium of the author's work upon the Science and Practice of Medicine. It simply embraces what the author believes to be essential to make it a book of reference for the general practitioner, if he is disposed to consult such abridged works, but it is more especially designed for the use of students. The book, therefore, contains definitions, a method for examining patients, a classification and general outline of a large number of diseases.

There is one very disagreeable feature in the work, and that is, the references to the author's treatise upon the Science and Practice of Medicine are so numerous that, if the student desires to fully understand the meaning of the writer, it becomes necessary to purchase both. This grows out of the fact that when a reference is made, it is, in many instances, in lieu of a few words in continuation of the subject under notice, which would avoid the necessity for any reference whatever.

For example, on p. 32 the writer says that "one of the most important results of the existence of inflammation is the material change that occurs in conditions for healthy nutrition of the affected part; and for details regarding these altered conditions the reader is referred to the Science and Practice of Medicine," etc.

It is the "details on the altered conditions" referred to by the author that make up the essential and most interesting part of the discussion, and just as the reader is reaching forward in anticipation of something that shall shed some new light, or at least let in the light of the author's own opinion upon the question, he is confronted by a reference to a ponderous work not at hand. In this respect, the book might be materially improved, and made more complete without increasing its size to any great extent.

Notwithstanding this disagreeable feature, the book contains much that will aid the student in the pursuit of his studies. The second chapter is worthy of his special attention, for in it is a key to success as a medical practitioner. It is devoted to what the author calls "case-taking," and methodical examination of patients.

"If," says the writer, "the attempts of a beginner are watched, who sets about the examination of a patient without any definite method, it will be seen that he wanders in his inquiries from one part of the body to another. He asks pointless and fruitless questions, and finally jumps at hasty conclusions, which are generally erroneous."

These remarks, however, need not be restricted to the new beginner, for many a poor fellow, who claims to be a worthy practitioner, has found himself in an awkward position, simply because he has not been sufficiently thorough in examining his patient. Such may learn that there is no safer method of making a thorough examination than by closely adhering to some system in conducting it. In this respect, therefore, the book may be studied with profit by many who have become graduates in medicine.

ERYSIPELAS AND CHILDBED FEVER. By THOS. C. MINOR, M.D. Cincinnati: Robert Clarke & Co. 1874.

In this monograph of 130 pages the author first gives an historical outline of erysipelas and childbed fever, showing the opinions of various authors regarding the connection of the two diseases and their contagious properties; followed by a study of both affections as they prevailed sporadically in the United States during the "census year, 1870;" and last of all, an account of the diseases as they have appeared in Hamilton county, for the past eight years, with the history of a puerperal-fever epidemic observed in south-western Ohio, in the winter of 1872.

The statistics of the mortality from erysipelas and puerperal fever in the different States and Territories, for the year 1870, are carefully arranged by the author into tables, showing the number of fatal cases in each State in every month; the annual mean temperature and rainfall is also noted, with the population of each State.

Able generalizations are drawn from a minute and careful study of these tables; and in the "recapitulation," the author states that he has fully described the 3,162 fatal cases of erysipelas, and the 1,828 cases of puerperal fever which occurred in the United States in 1870, although no general epidemic of either disease seems to have prevailed. The nativity of the decedents from both diseases is given, and a table showing that more men than women die of erysipelas; and that the months of greatest mortality from erysipelas were March and April, while the most deaths from puerperal fever occurred in March. Under the head of "The Relation of Climate to the two Diseases," Dr. Minor concludes that altitude rather favors the development of any erysipelatous tendency that may exist, while it tends to diminish the tendency toward puerperal fever. Both diseases prevail also whether the

season is wet or dry. A tabular statement giving the age of the decedents from erysipelas shows that infancy and old age are the periods of life when the human being is most apt to become the victim of that disease; while the most deaths from puerperal fever are recorded between the ages of 20 and 25 years. The author concludes his valuable collection of statistics of the two diseases by asking the question, "Is there a connection between erysipelas and puerperal fever?" which he attempts to answer in the following propositions:—1. Erysipelas and puerperal fever seem to prevail together throughout all the States. 2. Any marked increase in one locality of one disease, seems to be accompanied by a corresponding increase of the other. 3. Where histories of past epidemics of either disease are obtainable from any of the States, the seeming connection of the two diseases was noticed by physicians at the time of such epidemics, and remarked on. 4. For these reasons we are, I think, justified in concluding that there is an intimate connection existing between puerperal fever and erysipelas. As a rule, the book is written in a clear and concise way, although we note several specimens of a florid style of writing which we think unbecoming in a medical work, of which the following, on page 53, is an example. "Florida—that beautiful land, where the eternal kiss of a summer's balmy sunshine lingers on the lips of a warm, tropical nature, scented with the breath of incense-breathing exotics, musical with the tintinnabulations of richly-plumaged warblers. Land of lazy, tremulous languors, where the weary invalid convalesces while dreaming the time away in a delicious 'dolce far niente' state!" etc.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, March 24, 1875.

DR. F. DELAFIELD in the Chair.

DR. JANEWAY reported, on behalf of the Microscopical Committee, that the specimen presented by Dr. Kipp, at the last meeting, was one of carcinoma.

A VICTIM OF ABORTION.

DR. FINNELL presented the uterus and appendages taken from a woman who had been the victim of abortion. She was twenty-four years of age. After missing two menstrual periods, and on the eve of the third, she determined upon having an abortion produced. After the operation was performed she returned to her residence, and the day following was seized with a chill. She died in the course of ten days afterwards with metro-peritonitis.

Dr. McWhinnie, deputy-coroner, made the post-mortem, Dr. Finnell assisting. In the right ovary was a corpus luteum three months old; it was eight lines in length, four in breadth, and contained a characteristic clot. The opposite ovary contained a cyst the size of a small orange, in which was a quantity of bloody serum. The uterus itself was smooth, polished, and unchanged in appearance. There was no redness in the interior, save in the site of the detachment of the placenta. A slight depression in the side of the neck of the uterus, merely involving the mucous membrane, showed that the instrument used was probably a catheter or large-sized probe. The peritoneal cavity contained over a pint of sero-purulent fluid.

UTERINE POLYPUS—PERSISTENT UTERINE HEMORRHAGE.

DR. SELL showed a small uterine polypus which contained over a pint of sero-purulent fluid he had removed from a lady who, for three years previously, had been subject to persistent uterine hemorrhages. On digital examination the tumor was found protruding through the cervix, was pedunculated, and was removed without trouble by torsion. The effects following the operation were marked and decided, the patient having had no more unnatural sanguineous discharges.

MULTIPLE EXOSTOSIS.

DR. GIBNEY presented a living specimen, a boy aged thirteen years, who was the subject of rather remarkable exostoses. The patient came under Dr. G.'s notice on the 15th of March last, to be examined for hip-joint disease. On examination none of the symptoms of this disease were observed, but at the upper end of each tibia, at the proximal extremity of each humerus, were well-marked exostoses; also one around the left index finger, very much in the form of a ring.

The patient had been healthy up to his sixth year, when he had a severe attack of scarlet fever, with attendant nephritis. Within a year afterwards he was attacked with what seemed to be acute rheumatism, which confined him to his bed for a long time. Three years ago he began to complain of pain in his right hip, which symptom subsided after two or three weeks, to return within two or three months. He then had perfect immunity from pain until October, when it reappeared in the hip, and appeared to be aggravated after sitting a while. Dr. Janeway, who saw the case, suggested that some of those bony growths were also in the neighborhood of the hip-joint, giving rise to the symptoms complained of.

DR. JANEWAY remarked that he had recently seen a case in a young man, aged eighteen years, but in which the exostosis was a single one, and was situated on the inner condyle of the right femur.

POTT'S DISEASE OF THE SPINE CAUSING REFLECTED IRRITATION AND DISEASE OF GENITO-URINARY APPARATUS.

DR. F. N. OTIS presented a specimen of caries of the spine with the following history: A gentleman sent for me to see him, four years ago last summer, at Lake George. He had been a subject of hip-joint disease in his youth, and he was then forty years of age. For the previous fifteen years he had been what might be almost considered an athlete, having cultivated his muscular power to a very remarkable extent notwithstanding his lameness. He had been rowing a certain day, as was his custom, for several hours, when he was somewhat suddenly taken with a desire to pass water, and this continued at intervals of half an hour to an hour for several days, at the end of which time I was sent for. The urine was normal in appearance, with no deposit, and there was some straining after micturition. Upon examination of the bladder nothing was found to account for the symptoms. The difficulty of urinating continued without cessation for two years, except when temporarily relieved by the administration of narcotics. At this latter time he had come to have a considerable amount of catarrhal inflammation of the bladder, which had come on very gradually. He had never had any gonorrhœa, nor any other disease of the genito-urinary apparatus. At the time referred to he was seen in consultation by Dr. Markoe. The patient had some occasional discharges of blood after micturition,

after which discharges he would have relief from the pain which preceded these attacks. Having considerable catarrhal trouble, and some considerable pus in the urine, it was thought probable that he had stone in the bladder. He was put under the influence of ether, and examined for stone, but with negative results. His difficulty then went on increasing, and having found a very large quantity of calcareous matter, the idea of calculous disease was confirmed, and the supposition entertained that possibly the stone was enclosed in a pouch of the bladder. The case went on for another year with very little change. He was treated by different narcotics and sedatives in order to relieve the great irritation, which not only was felt in his frequent urination but which extended throughout the urethral canal.

About the third year of his trouble Dr. Van Buren saw him with me, and at first the doctor was of the opinion that he had stone, but this opinion was not confirmed, and still his symptoms went on. The spasm at the neck of the bladder was then terrific, and would occur as often as every ten minutes. His life seemed to be one prolonged torture. Sometimes he would have an interval of a half an hour of freedom from pain, but these intervals were by no means frequent.

Two years ago, three years after the commencement of his trouble, making occasional examinations of the urine I found that there was more or less epithelial matter from the ureters and from the pelvis of the kidney, and I urged an operation for the stone which I supposed to be present. Believing this to be the only method by which his life might be prolonged, Drs. Van Buren, Gouley, and Markoe were called in consultation, and it was decided, although there was very great doubt as to the presence of stone, still it was absolutely necessary that the irritation be stopped in some way or grave and fatal kidney disease would result. It was determined to relieve the cystitis in any event by local treatment, and in order to do this he was cut for stone. The median operation was accordingly performed upon him by Dr. Gouley, in the presence of Drs. Van Buren, Markoe, and myself. After this operation he improved somewhat. I should say no stone was found, much to our disappointment. Although he did well for several months, he failed to regain comfortable health. For about a year, notwithstanding he went through what in any one else might be considered great suffering, he was comparatively comfortable. He came down last autumn, and on arriving at home I was sent for to see him. I found him exceedingly comfortable. He had complete relief from his bladder trouble, and was only passing his water once every three or four hours. This seemed very strange to me. His wife mentioned at the time in a very casual way that she thought he had an extra lump in his back. He assured me, however, that it had existed for a very long time. I found, on examination, about the region of the seventh or eighth dorsal vertebra, a distinct projection, and it seemed to me that it was evidently Pott's disease of the spine. He had previously complained of a great deal of pain in the back, but it had been located in the region of the kidney, and was supposed to be connected with his general trouble. I sent at once for Dr. Van Buren, and he agreed with me fully in regard to the presence of spinal trouble, and it was decided to place him under the care of Dr. Chas. F. Taylor. Dr. Taylor then became connected with the case, and was decidedly of the opinion that it was one for treatment by his method of support, and applied an instrument which he adapted to the spine. This treat-

ment was continued for some months; but he became very restless and uneasy, and his trouble in urination came back. At the time this trouble left him the pain which he experienced lower down became localized just above the hips in a plane with their top. He was finally put upon a water-bed, but after a month more of trial with the instrument it was found impossible to wear it. Just about that time a diarrhoea came on, was very profuse and obstinate for a week, and ceased apparently of its own accord. Then his bladder trouble increased again and was attended with severe spasmodic pains during micturition, which pains were mostly situated at the neck of the bladder and at the end of the penis. Within two or three days before his death he very accidentally obtained instant relief to the pains by the application of snow to the end of the penis. He died two weeks ago, apparently from a uremic convulsion.

A post-mortem examination revealed first a half pint of laudable-looking pus in the cavity of the peritonæum, which pus was found connected, underneath the sheath of the psoas muscle, with two abscesses located upon the left side of the spine, in the neighborhood of the eighth dorsal vertebra, at which situation the posterior surface of the left lung was adherent. This condition explained a very distressing cough from which he suffered during the last few months of his life. The right kidney was found to be the seat of a cystic degeneration. There was no dilatation of the ureter between the kidney and bladder, and no obstruction in the ureter. The left kidney was three or four times larger than the right, was the seat of waxy degeneration, and the subject of pyonephritis to a very considerable extent. A large portion of the kidney was involved in ulceration, and there was a collection of purulent material which extended more or less throughout the calices. The bladder was thickened and contracted, but there was no evidence of any ulcerative trouble. There was no stone in the bladder, but there was an admirable cul-de-sac to conceal one. One testicle was atrophied, the other considerably enlarged, and in its inferior portion was the seat of a disease the gross appearances of which were quite characteristic of tuberculous disease.

Dr. Otis, in concluding his remarks upon the case, thought that he had good reasons for referring the genito-urinary troubles to reflected irritation from the disease in the spine.

Dr. DELAFIELD, to whom the kidneys and testicles had been referred for examination, remarked that they were classical representatives of tuberculous degeneration.

SYPHILITIC BRAIN LESIONS WITHOUT A SYPHILITIC HISTORY.

Dr. DELAFIELD then exhibited two microscopical specimens. The patient to whom they belonged was a Frenchman, æt. 26, who was admitted to the Roosevelt Hospital on the 1st of April, 1874. He strenuously denied having had venereal disease. About a year and a half before he was struck in the left testicle, and suffered from more or less inflammation of the part for six months. Since that time his urine had been scanty and was frequently passed. When admitted, his left scrotum was filled with a small glandular tumor. On the 6th of April it was discovered that he passed blood and pus in his urine, and by rectal examination it was likewise ascertained that the right side of the prostate gland was enlarged. There was some difference of opinion in regard to the nature of the tumor of the testicle, some of the surgeons believing it to be syphilitic in character, and others serofulous.

On the 3d of June he was suddenly seized with headache and a good deal of difficulty in speaking. On the 6th of June he lost his speech altogether, and on the 9th of June he commenced to vomit, the following day became comatose, and on the 13th of June he died.

When the autopsy was made it was found that the left kidney was enlarged and far advanced in tuberculous nephritis. The left seminal vesicle, prostate, and left testicle were all in this same cheesy condition. The bladder contained pus, and its mucous membrane was covered with fibrine. The lungs presented the lesions of chronic bronchitis. The brain exhibited very marked lesions. Wherever the dura mater was removed the pia mater was seen to have lost its natural glistening appearance, and was of a very dry and dull appearance. There was a good deal of turbid serum beneath it. Besides, upon the surface of the brain there were numerous points of what seemed to be gummy tumors, collections of gelatinous material beneath the pia mater, and extending into the substance of the brain. Some of these growths were a little cheesy, but most of them were of a gelatinous appearance. They grew from underneath the pia mater down between the convolutions of the brain, and were composed simply of coagulable fibrine, a considerable number of large rounded cells, as in inflammation of the brain, and also small rounded cells such as found in gummy tumors.

Dr. Delafield remarked that this was a case in which there was no syphilitic history, no syphilitic symptoms, and yet the lesions in the brain were exactly those which we are accustomed to find in gummy tumors of that organ. The question would therefore arise in this case whether these tumors might not be of the same nature as those found in the genito-urinary organs. The question was by no means an easy one to answer.

SUDDEN DEATH AFTER LABOR WITHOUT APPARENT LESIONS.

Dr. D. also related the case of a woman who was confined in the Charity Hospital boat. She was delivered at half-past 3 on Tuesday morning. There was nothing abnormal about the labor, and everything progressed favorably, until suddenly, half an hour after the birth of the child, her pulse began to sink, and despite every effort she died within two hours afterwards. At the autopsy nothing abnormal was found, the case resolving itself into one of sudden death without apparent lesions.

The Society then went into Executive Session.

Obituary.

T. BLANCH SMITH, M.D.,

NYACK, N. Y.

DIED at Nyack, Rockland Co., N. Y., on Wednesday, April 14th, T. Blanch Smith, M.D. The doctor was born at Blauveltville in the same county, Nov. 27th, 1835. He attended the district school there, until, at the age of twelve, his parents having changed their residence to New York, he entered the school of Mr. G. P. Quackenbos in that city. In this grammar school he remained until, having chosen for his life-work the practice of medicine, he left the city, and entered the office of Dr. M. C. Hasbrouck, of Middletown, Rockland Co., N. Y. In the year 1852 he attended lectures at the Medical College at Geneva, N. Y., then entered

the College of Physicians and Surgeons, New York, and after two full courses, graduated in 1855. Immediately upon graduation he succeeded Dr. Hasbrouck at Middletown, and continued to practice there until June, 1858, when he removed to Tappan, N. Y.

He married Ellen C. Van Orden, of Spring Valley, Dec. 31st, 1855. In the year 1870 he moved to Nyack. He filled, successively, the offices of secretary, treasurer, and president of the Rockland Co. Medical Society.

In Feb., 1873, he was made a permanent member of the Medical Society of the State of New York. He was elected President of the Village of Nyack, March, 1874, and re-elected March, 1875.

Dr. Smith, from the beginning to the end of his professional career, was an earnest student. He did not fall into routine, or content himself with such knowledge as he had easily acquired, but constantly purchased and studied standard books, and sought, by attending occasional lectures and clinics at the colleges in New York, and by frequenting the meetings of learned societies, to keep himself thoroughly informed of every discovery and of every real advance in the science and art to which he was so enthusiastically devoted. It is not saying too much to affirm that there was probably not a more careful student of the indications for and the uses of drugs in the profession in the State. He became a real master in the art of prescribing, and all through the county, where he was best known, this fact will be cheerfully attested by his professional brethren. He was chivalrous in his loyalty to his medical brethren, and did much to aid them, in the society of his county, in the maintenance of that confidence and good order upon which the dignity and usefulness of the profession so largely depend.

The doctor was apprehensive that he would fall a victim to pulmonary or cardiac disease, as there was a marked tendency to the same in his family. Occasionally, moreover, he would break down suddenly in health and then have a small hemoptysis. His worst fears were finally realized in the character of his death. On Monday morning early (April 12th) he was called out suddenly by an alarm of fire in the village, was greatly exposed to cold and wet; was seized that night with severe pain in the chest; had hemoptysis; suffered greatly through Tuesday, and on Wednesday, April 14th, at 10.30 A.M., suddenly died. For some hours before death, there had been dyspnoea with great cyanosis. As there was no autopsy, the immediate cause of death cannot be stated.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 10th to April 17th, 1875.

EDWARDS, L. A., Surgeon.—Granted leave of absence for one month on surgeon's certificate of disability. S. O. 71, Mil. Division of the Atlantic, April 14, 1875.

ROSE, GEO. S., Assistant Surgeon.—Assigned to temporary duty at Madison Barracks, N. Y. S. O. 69, Mil. Division of the Atlantic, April 10, 1875.

ELBREY, F. W., Assistant Surgeon.—To report in person to the Commanding General Department of the South for assignment to duty. S. O. 63, A. G. O., April 10, 1875.

CHERBONNIER, A. V., Medical Store-keeper.—Granted leave of absence for one month. S. O. 63, c. s., A. G. O.

Medical Items and News.

CONSAQUINEOUS MARRIAGES.—Mr. Geo. H. Darwin, in an exhaustive paper on the marriages of first consins, and their effects, sums up the results of his investigations as follows: 1. Consanguinity of parents is injurious to the offspring. 2. Where the children seem to escape, the injury may show itself in the grand-children. 3. In many isolated cases, and even groups of cases, no injurious result can be detected. 4. These unions influence idiocy and imbecility more than the forms of insanity acquired later in life. 5. The frequency of these unions in Scotland (although not so great as supposed) somewhat increases the amount of idiocy there.

NURSING IN NORWAY.—Mr. John Campbell describes, in an English journal, the nursing system in vogue in Norway, and commends its practical nature.

"Almost every Norwegian parish has its *jordemoder*, or professional nurse—a woman educated, as I understand, at a hospital, and who acts under the direction of the doctor of the district, being qualified to attend confinements (where in Norway a doctor is seldom thought necessary), to cup, bleed, etc. On the occasion of a slight contusion, received through a fall, a few summers ago, the doctor whom I consulted advised cupping, and this was done at my inn by the *jordemoder*."

He suggests that such a class of women would be extremely serviceable among the poor, and says that Sweden and Denmark have organized systems of instruction and supervision of midwives.

THE INTERNATIONAL MEDICAL CONGRESS AT BRUSSELS.—The fourth session of the periodical International Congress of Medical Science will commence at Brussels on September 19th, 1875, and will last a week. It will be composed of those native and foreign medical men who send in their names to the Committee, and who alone will have the right of taking part in the discussions. The only expense incurred by members will be 12½ *francs* (\$2.38) for a copy of the Report of the Proceedings of the Session. A card of admission will be forwarded with the receipt for this subscription. Applications for admission are to be made on and after July 1st; and members' names will be forwarded and cards of membership distributed on the afternoon of September 18th, and the morning of the 19th. Members must have their names put down in the section to which they desire to belong. A member may belong to several sections. The Congress will meet twice daily; in the morning for the work of the sections, in the afternoon for general meetings, which will be devoted to conferences on questions of general medical interest not included in the programme, and to reading the reports of the sections and discussion of their contents. Members wishing to read papers on any subject not included in the programme must give notice to the Committee at least a month before the opening of the Congress. No one will be allowed to speak more than twenty minutes; this restriction, however, does not extend to the sectional reporters. All papers read at the Congress must be left at the Committee-room for publication at the discretion of the Committee. The proceedings will generally be conducted in the French language, but foreign members will be allowed to express themselves in their native tongue. If wished, the sense of their discourse will be briefly interpreted to the meeting. The Committee consists of M. Vle-

mineckx, President; and MM. Deronbaix, Bellefroid, and Crocq, members; with M. Warlont, General Secretary, to whom all communications relating to the Congress will be addressed. The programme of the Congress is as follows: 1. *Medicine* (comprising Pathology, Pathological Anatomy, and Therapeutics); the Prophylaxis of Cholera; Alcohol in Therapeutics; the Inoculability of Tubercle. 2. *Surgery* (comprising Military Surgery and Syphilography); on Surgical Anæsthesia, and Dressing of Wounds after Operation. 3. *Obstetrics* (including Diseases of Women and Children); Lying-in Hospitals. 4. *Biological Science* (comprising Anatomy, Physiology, Comparative Medicine); the Vaso-motor Nerves, and their mode of Action; the Value of Experiments based on Artificial Circulation. 5. *Public Medicine* (comprising Hygiene, Forensic Medicine, Medical Statistics); the Means of making Workshops in which Phosphorus may be manipulated without Detriment to Health; the Organization of the Public-Health Service, the Manufacture of Beer. 6. *Ophthalmology*: Defects of Vision in relation to the Military Service. 7. *Otology*: the means of Measuring Hearing and Registering in an uniform manner in all Countries; Defects of Hearing in relation to the Military Service. 8. *Pharmacology*: Should the Medical Employment of chemically defined Principles immediately be extended, and should the Preparations of them be multiplied in the Pharmacopœia? The Establishment of an Universal Pharmacopœia.

THE NEW YORK DIET KITCHEN.—At the recent annual meeting of this charity, at 374 Second Avenue, Mrs. William C. Whitney, Secretary of the Association, read her report, in which she stated that thirty patients were provided with properly prepared food daily. The Board of Apportionment had allowed the kitchen \$700, which had been applied to the equipment of another kitchen at No. 438 West Thirty-sixth Street. The design of the managers is to extend the system, so as to have a diet kitchen in every dispensary district, as at first suggested by Dr. C. H. Atwater. The report of the Treasurer, Mrs. W. Langdon Ward, showed a balance on hand of \$1,843.82, the total receipts having been \$3,364.41.

A PRIZE FOR A THESIS ON INSANITY.—Some of the descendants of William and Samuel Tuke have placed at the disposal of the Medico-Psychological Association the sum of one hundred guineas, which the Association offers as a prize for "the best series of original cases and commentary illustrative of the somatic etiology of various forms of insanity, accompanied, when possible, in fatal cases, by reports of post-mortem examinations and microscopic preparations, their bearing on the symptoms being pointed out.

"Cases not seen by the writer may be cited, but must be distinguished from those actually witnessed by himself."

The prize will be open to all, without restriction as to country, profession, etc., but the right is reserved to withhold it should there be no essay of sufficient merit. Essays to be written in English, and not in the author's handwriting; to be sent with a sealed envelope, having the motto of the essay, and containing the name of the writer, to W. Rhys Williams, Hon. Sec. Bethlehem Royal Hospital, London.

DR. HORACE DOBELL was lately the recipient of a vote of thanks, handsomely illuminated on vellum, on his retirement from the post of Physician to the Royal Hospital for Diseases of the Chest, after sixteen years of service. He has also been elected consulting physician to the hospital.

SOME OF THE EFFECTS PRODUCED BY SEWER-GAS.—Dr. Fergus, of Glasgow, at the meeting of the Birmingham Sanitary Conference, related the results of experiments as to the value of water-trapping as a means of preventing sewer-gas from entering dwelling-houses. The principal object Dr. F. had in view was to show that the few inches of water which, as a rule, are placed as a barrier between the sewers and the interior of houses, and which are dignified with the name of syphon-trap, afford, in reality, no protection against sewer-poisoning. He exhibited at the conference a number of decayed and perforated soil-pipes, the perforations being from within outwards, and being so situated on the upper surface of the pipes that the destruction of lead could not possibly have been caused by any liquids that had passed through them. The pipe which was most frequently so affected was stated to be the cross one, leading from the closet to the main descending soil-pipe; and if there were a bend or arch in the pipe, the upper surface of the bend or arch would become perforated.

Dr. Fergus says, unhesitatingly, that this result is due to the action of sewer-gas, and he supports this view by showing the increased rapidity with which the destructive action takes place, when the soil-pipes are unventilated. In many houses in which diphtheria and typhoid fever had existed, the inmates had complained of offensive odors emanating from the water-closets, and on examination he had found the soil-pipes to be perforated. But what was most striking was the fact that these house soil-pipes were in each case trapped before they entered the drains, and yet the sewer-air was able to get through the trapping and destroy the lead.

As experiments, Dr. Fergus had procured a series of tubes, bent so as to resemble the ordinary so-called syphon-traps, and in the lower curve of each of these tubes water was placed to affect the trapping. Various gases were then admitted without pressure into the tubes. The first experiment was carried out with ammonia, and it was found that in fifteen minutes it had passed up the tube through the water, and had discharged the acid with which some litmus paper, suspended over the upper surface of the water, had been reddened. Very similar results were produced with other gases, quite irrespectively of their being lighter or heavier than atmospheric air; thus sulphurous acid passed through the water in an hour, and carbonic acid gas and sulphuretted hydrogen in about three hours. The same experiments were repeated after an open pipe had been inserted into the bend of the tube, so as to resemble the ventilating pipe of an ordinary water-closet soil-pipe, and the same results were obtained, although the reaction was longer in each case in showing itself. The results obtained by Dr. Fergus are interesting as pointing out strongly how misplaced is the confidence which the public have been led to repose in the traps with which nearly every house is provided, and how important it is not only thoroughly to ventilate our house-drains, but also to subject our soil-pipes to periodical examination.—*British Medical Journal*, February 27, 1875.

NEW YORK INFIRMARY FOR WOMEN AND CHILDREN.—A fair for the benefit of this institution is to be held on the 1st and 3d of May, from 10 A.M. to 10 P.M., at the new site occupied by the institution, No. 5 Livingston Place, Stuyvesant Square.

GARBALDI'S HEALTH is said to be suffering from the amount of "interviewing" to which he is subjected in addition to his other duties.

RECEPTION HOSPITALS FOR LYING-IN CASES.—The Commissioners of Public Charities and Correction have accepted the offer of the physicians of the House of Reception to the New York Infant Asylum, to use that institution in cases of maternity at an emergency, so as to prevent a repetition of such sad scenes as those which attended the death of Lizzie Stern. For the present, therefore, the ambulance surgeons will leave all cases found below Fourteenth Street at that institution, all above that line at Bellevue Hospital.

DR. ALEXANDER GOSCHEN, the editor of the well-known *Deutsche Klinik*, recently died quite suddenly at Berlin, of pneumonia, in the sixty-second year of his age. He founded the *Deutsche Klinik* twenty-six years ago, and edited it to the time of his death, it being the first great medical weekly journal ever established in Germany.

THE MEDICAL ASSOCIATION OF VIRGINIA is to meet at Richmond on the 20th of October.

POSTURAL TREATMENT OF RETROVERSION.—Dr. Aveling records, in the *Obstetrical Journal*, the following anecdote: The postural treatment of retroversion consists in lying or reclining upon the sides, or, still better, upon the face. Prostration is also an admirable attitude. A remarkable anecdote in support of this is told of a lady suffering from retroversion, who made her complaint the subject of prayer, and was surprised to find it answered only when she was upon her knees. All pain ceased during the devotional act—that is, when she unconsciously adopted the proper postural treatment.

THE SEVENTH ANNUAL MEETING OF THE PRESBYTERIAN HOSPITAL was held on the 14th inst., when it was reported that about three hundred patients had been treated during the year. The pecuniary affairs of the hospital are said to be in a prosperous condition.

THE ASSOCIATION OF MEDICAL OFFICERS OF C. S. ARMY AND NAVY will hold its next meeting at Richmond, Va., on the 19th of October next, instead of July, at 11 o'clock A.M.

UNIVERSITY OF PENNSYLVANIA.—At the last meeting of the trustees of this institution, Dr. James Tyson was elected Professor of Pathology, Dr. Louis A. Duhring, Professor of Diseases of the Skin, and Dr. H. C. Wood, Professor of Diseases of the Nervous System in the University Hospital.

VON LUSCHKA, Professor of Anatomy in Tübingen, died on March 1st.

ANOTHER CENTENARIAN.—Baroness Schuhaj recently died in Prag at the age of 118—having been born in 1757.

WEEKLY BULLETIN OF MEETINGS OF SOCIETIES.

Monday, April 26.—Medical Society of County of New York: "Conium; and its uses in Diseases of the Eye," by Edward Curtis, M.D.

Tuesday, April 27.—American Microscopical Society. Yorkville Medical Association.

Wednesday, April 28.—New York Pathological Society.

Friday, April 30.—Medical Library and Journal Assoc.

Original Lecture.

A NEW METHOD OF ARRESTING HEMORRHAGE.

A CLINICAL LECTURE DELIVERED BEFORE THE MEDICAL DEPARTMENT OF UNIVERSITY OF WOOSTER, CLEVELAND, OHIO.

By GUSTAV C. E. WEBER, M.D.,

PROF. OF CLINICAL SURGERY.

GENTLEMEN: I have selected this subject for discussion, partly with a view of making those of you who, as yet, are strangers to the various phases of the operating room, familiar with one of the most important tasks of a surgeon; partly, in order to explain to those who have witnessed similar operations, the differences in the modo operandi which I shall employ, and which they will readily detect—for I propose in this operation to employ the so-called "bloodless method" of operating, as suggested by Esmarch—and, also, to follow a plan devised by myself to secure permanent closure of divided arteries.

The subject of hemorrhage, or rather of surgical hemorrhage, is of vast importance. It should, at the very beginning of the lectures on operative surgery, receive on your part its full share of study and careful consideration. Not until you understand it fully, and are conscious of being able to master it under any circumstance, will you be able to undertake even an inferior surgical operation with satisfaction to yourself, with safety to your patient. The skill, dexterity, and coolness, which mark the experienced surgeon during the performance of the most difficult operation, spring from his consciousness that, let come what will, he is master of any hemorrhage that may occur.

The division of any structure of the body necessitated by surgical therapeutics, is naturally accompanied by more or less bleeding. At nearly every step of an operation hemorrhage presents itself to the operator, either in the character of capillary, parenchymatous, venous, or arterial. Knowing that there exists a marked difference in the size of the various vessels of the body, in the quantity of blood they carry, in the structure of their coats, in the influence of the "vis a tergo" upon the column of blood within them, in the various vascular territories and, also, in the tissue surrounding them—it is apparent, that those four varieties of hemorrhage differ in practical significance. In fact, you will readily become convinced, that under ordinary circumstances arterial hemorrhage alone is the special object of a surgeon's care and anxiety. Conditions exist, however—and they are sometimes hereditary—which may lead to an excessive, often dangerous, loss of blood from the division of even the finest capillaries, where by changes in the chemical and histological composition of the blood, by a modification of the structure of the vessel, and, probably, of nerve power of the vaso-motor nerve, a spontaneous arrest of the flow of blood is impossible. These conditions sometimes exist constitutionally, and are described under the term of Hæmophilia. Then again the surrounding tissue may prevent the change in the divided capillaries which is necessary for their spontaneous closure, and with which I shall presently attempt to make you familiar. Thus in tense and unyielding tissue, in the parenchyma of some of the organs of the body, a division even of fine

and delicate vessels is followed by somewhat profuse bleeding.

Ordinarily, capillary and parenchymatous as well as venous bleedings are spontaneously arrested without the least assistance on the part of the surgeon. And you will even observe arteries of considerable size cease bleeding, without the application of any of the known means for artificial arrest of hemorrhage. Many of the gentlemen will have wondered in coming from the dissecting table, where they followed with the scalpel the numerous anastomoses of well-injected principal arteries in an extremity, why in the operating room, after all, only few of these vessels require the attention of the operator. At this period in the investigation of the subject, the questions naturally arise: How does spontaneous arrest of hemorrhage take place in the divided vessels? How does nature succeed in closing, temporarily or permanently, the opening in a divided vessel?

In order to appreciate the therapeutical value of the various means which we propose for the arrest of hemorrhage from any of the vessels, it will be necessary to understand, as far as we can, the process nature makes use of for that purpose. I am sorry to be compelled to acknowledge my inability to present you with undisputed facts in the premises; for it must be admitted by every one familiar with the results of the investigation of those who have contributed to the elucidation of this interesting subject, that its discussion cannot be considered definitively and permanently closed. Yet there is sufficient knowledge to explain this natural process approximately, and with it the correctness of at least some of our therapeutic agents. We shall have to premise a short sketch of the histology of the blood-vessels, in order to understand what, at the present day, is generally conceded to be the sum and substance of this matter.

You will not expect me to enter into details; they would lead me far beyond the limits of an occasion like the one which has brought us together here to-day. For a more minute study of this subject let me refer you to the elaborate article "On the Blood-vessels" in Stricker's Handbook of Histology, by C. J. Eberth; and, also, to the chapters "On the Tissues of the Body" in the carefully written work entitled "The Histology and Histochemistry of Man" of Prof. Frey of Zurich.

The vessels which carry blood in every direction over the body, viz., the arteries, veins, and capillaries, are membranous tubes of variable size and form, possessed of an extraordinary amount of elasticity and contractility. These qualities vary greatly with the size and the arrangement, quantity and quality, of the tissue of which they are composed. Thus in the minute capillaries, composed simply of spindle-shaped or polygonal cells, fitted together so as to form the finest of cellular membrane, we observe quite active, vital contractility, which in the larger ones, and in the arteries and veins, by the interposition of elastic connective and muscular tissue in their walls, obtain a degree of elasticity and contractility which intimately corresponds with the necessities of their function in different regions of the body.

The membranes of which these vascular tubes are constructed vary in thickness and number with the different vessels. Thus, as we have already indicated, the finest capillaries, of a diameter of not more than 0.0045–0.0068 mm., are composed of a very delicate membrane, which is perfectly transparent and apparently structureless until treated with a solution of nitrate of silver, when its cellular character is proved. In larger capillaries, which are situated near the arteries or veins, this cellular membrane is strengthened by the

addition of another delicate, and homogeneous membrane; and in still larger ones, by an additional covering of a layer of delicate connective tissue. As the capillaries gradually merge into the ultimate termination of the arteries and veins, the thickness of their walls is further increased by the fact, that between the two internal membranes and the layer of connective tissue, a thin layer of contractile fibrillary cells and distinct nuclei (arranged circularly around the longitudinal axis of the vessels) is interposed. All these layers observed in the larger capillaries gradually grow thicker, and become more important, until in the arteries and veins we recognize three distinct coats of the vessel, viz., an external one or *tunica adventitia*, composed of fibrous and elastic tissue with its fibrillæ and filaments surrounding it spirally, obliquely, and netlike; next, a middle coat, or *tunica media*, this coat forming the main thickness of the arterial vessel. It has a yellowish color, consists mainly of muscular and elastic tissue, and surrounds the vessels for the most part circularly. The third is the internal coat, or *tunica interna*, formed by the original cellular membrane, as observed in the most primitive form of capillaries. It consists of a homogeneous elastic basement membrane, and of layers of elastic tissue, forming netted and fenestrated meshes pursuing a longitudinal direction. To the external coat the vessels mainly owe their tenacity; to the middle and internal, their elasticity and contractility. Veins and arteries differ greatly as to the relative amount of tissue in these three tunics, and in the arrangement of fibrous and elastic as well as muscular structures. It is this difference which furnishes the peculiar characteristic features of each set of vessels. Thus in the arteries of medium calibre, the middle tunic is the thickest and gives the vessel its peculiar cylindrical form, which enables us readily to distinguish an artery from a vein; whereas in veins the external coat is the thickest, the thickness increasing with the calibre of the vessel. In arteries, however, the middle coat, composed to a great extent of unstriated muscular tissue, varies inversely as the size of the vessel. Besides these three tunics proper which enter into the structure of vessels, the latter are loosely surrounded by a network of connective tissue. This helps to fix the tubes in the territories through which they pass, and in the largest arteries and veins it takes the character of an additional coat, surrounding them sheath-like, being unquestionably destined to maintain them in proper relation to the surrounding tissues. The three coats are nourished by the so-called vaso-vasorum vessels, which ramify mainly upon the middle and external coats; and their innervation is accomplished by the vaso-motor filaments of the sympathetic and spinal nerves.

The blood, gentlemen, which courses in these vessels, is a most complicated fluid, and the centre of all vegetative vital processes. According to calculations of Welker, it makes up in the new-born child about one-nineteenth, and in the adult one-thirteenth, of the entire weight of the body. Its various histological and chemical elements are maintained in proper reciprocal relations so long as it is propelled through the different channels of the vascular system with normal velocity, and according to the proper dynamic laws. But whenever those relations vary materially, or cease altogether, as when the blood escapes from its physiological abode, the fluid condition is lost, and the blood coagulates.

The coagulation of the blood is due to the solidification of its fluid intercellular substance, brought about by the formation of a body called fibrine. With our incomplete knowledge of the protein bodies of the animal organism, the character of fibrine cannot be ac-

curately stated. Chemically, it varies from the albumen of the blood, the chyle, and lymph, merely by a slightly higher degree of oxidation; yet, in its coagulation, it presents entirely different physical characters from those of coagulated albumen. It has been supposed that fibrine, as a distinct protein body, is held in solution in the blood-plasma, and that its physical features are evolved only when it leaves the body or when exposed to chemical and physical influences different from those which prevail during physiological position and motion. Experiment and observation, however, favor the views expressed by A. Schmidt. He maintains that blood and all fluids which yield fibrine contain a fibrinogenous and a fibrinoplastic substance. We call the former also "meta-globulin," and the latter "para-globulin," and believe the former to be contained in the blood-plasma, in nearly all serous fluids and fluids permeating muscular and connective tissue. The latter is bound to the cellular element of the blood and the structures, which contain the fibrinogenous substance. The fibrinoplastic power is set in activity whenever the fibrinogenous substances become subject to other than physiological influences. Now, while our understanding of the details concerning the coagulation of the blood is unquestionably rather limited, the clinical fact is authentic, that coagulation takes place, with somewhat variable rapidity, soon after the blood has left its accustomed channels in the living body, accidentally or otherwise; that, in fact, already on its way out, it congeals under ordinary circumstances, and forms proops of coagula that reach often to a considerable extent into the vessel from which the blood was derived. These ordinary circumstances exist, whenever the opening into the vascular territory is such that the blood-pressure is materially diminished in the province which furnishes the blood, so that the fibrinoplastic influence of the cellular elements of the blood can be fully exercised, and that the opening can retract within the surrounding muscular or connective tissue, pregnant with this same fibrinoplastic material. Experiment and clinical observation have shown that whenever the blood is expelled under almost normal blood-pressure, as in longitudinal wounds, or by division of large arterial trunks, the coagulation of the blood does not begin in the vessel. This would go to demonstrate that during the diminished pressure of the blood at the instant of its escape from a vessel, is the brief moment which calls out its fibrinoplastic property. Besides these general causes leading to the development of thrombus in an open blood-vessel, we can detect other conditions which will facilitate it and assist in the spontaneous arrest of hemorrhage. Thus the coagulability of the blood greatly increases with the increase in the amount of the loss of blood. Bruecke has demonstrated, that the last four drops of blood coming from an animal dying from hemorrhage, almost instantaneously coagulate, although under these circumstances the blood is excessively poor in fibrine.

We must recognize, then, in the physiological changes wrought by injury of a vessel, as well as in those of the surrounding textures, a potent element for or against the formation of clot. The various tissues, divided accidentally or otherwise, and the vessels, when severed, contract, both by their own vital character and by nerve influence; a mechanical act is thus brought to bear upon the blood. In the first place a certain amount of pressure will be exercised by the contracted tissue upon the vessels; and next the contracted vessels will furnish an impediment to the exit of blood, and assist in its coagulation. There can be no doubt as to the fact, that to this peculiar power

of coagulation of the blood, to the formation of a clot of blood or thrombus under proper conditions, is due the spontaneous arrest of hemorrhage from openings in the vascular tissue of the body. But in order that that formation should be possible, the opening evidently must be of a nature such as to cause the fibrinoplastic element of the blood and surrounding tissue to exert its power.

During the performance of a surgical operation, this is nearly always the case. Quite a number of blood-vessels, large and small, are opened at once, and owing to the collective escape of blood, the lateral blood-pressure is greatly diminished. Then, the tissue, by the application of the stimulant of the operation and by their own vital contractility, contract, press upon the sides of the vessels, and impede the flow of blood. Finally, the vessels themselves retract and contract, so as not only to furnish an obstacle to the flow of blood, but also to enable it at once to come in contact with the fibrinoplastic substance contained in the cellular elements of the surrounding tissue. If you will recollect the ingenious arrangement of the different layers of the coats of the vessels, and also their histological character, you can appreciate the quantity of retraction and contraction, and of impediment, which will be produced. You will then readily understand why it is that in many operations entailing quite extensive division of structures and vessels of different size, unaided nature is generally incompetent to prevent undue loss of blood. And you will be able to explain also, why in cutting very large vessels, we are compelled to interfere promptly, to prevent the disastrous effects which would follow uncontrolled hemorrhage.

In order, gentlemen, to make this subject still clearer to you, let us for a moment consider the nature of the changes which are observed to result from the inherent contractility of the more important vessels when divided. The typical form of these changes we can study in an artery of small size, which, when severed, presents the characteristic cylindrical form. The same changes, variable only in degree, can unquestionably be demonstrated in almost all the different vessels. The middle coat of a small-sized artery is the thickest of the three coats, and possesses beside the elastic fibres (arranged in circular and fenestrated network) considerable muscular tissue which will contract, when stimulated or deprived of the normal tension maintained by the presence of the blood. This contraction will be beyond the limit of the vital contraction of the internal tunic, more especially of its cellular lining, and must cause a folding up of this layer of the vessels. In fact, we find that this takes place to a considerable extent. The entire intima is fluted longitudinally as distinctly as the ruffles of a lady's garment, and this must offer considerable impediment to any flow of blood from the open mouth of the vessel. It is very probable, that this pleating of the intima is a very active stimulant to the formation of the clot. The middle coat in the larger arteries loses a great deal of its muscular elements, and the chances of spontaneous arrest of bleeding from such vessels are materially lessened. It is to my mind a proper question, whether this is due to the absence of the folding of the intima, or merely to the fact that the *vis a tergo* is increased so that a clot cannot resist it. If a clot can be formed, it will be proportionate to the dimensions of the vessel; hence in a larger vessel the clot is as competent to resist the impetus of the blood, as a smaller clot in a narrower vessel.

The external coat of the artery, composed mainly of longitudinal and oblique fibres, retracts the vessel after

division, so as frequently to conceal it within the surrounding tissues. The overlapping of these tissues also impedes the exit of the blood. From what has been said of all these physical changes in the injured vessel, it would seem rational to suppose that they are linked with the vital changes in the blood, and that thus the object of the spontaneous arrest of hemorrhage is attained.

The next question is of great interest and importance, on account of its bearing upon the various methods of treatment required when nature fails. It is this: "In what manner is the permanent closure of the vessel effected?" In former years, it was thought that inflammation furnished plastic material, which organized and filled up and obliterated the opening. Consequently it was the surgeon's mission, whenever it became necessary to employ artificial means for the temporary arrest of bleeding, to apply them in a manner such as would guarantee the supervention of inflammation. The surgeon was instructed to apply his ligature in a manner such as to break the brittle internal and middle coats, in the expectation that they would roll up and come together in the line of their fracture, and readily unite by adhesive inflammation. It was believed that without this the process of permanent closure could not be completed, and that secondary hemorrhage would then naturally follow.

Virchow, Billroth, and C. O. Weber, however, have endeavored to establish the fact that the final closure was due not to inflammatory action, but to the organization of a clot. Of late, several contradictory statements have been published. In 1869, Dr. Tschausoff published an elaborate article in *The Archive of Clinical Surgery of Langenbeck*. "On the Thrombus following Ligature," in which he tries to prove by a series of carefully conducted experiments, that the thrombus itself does not organize, but that it is only a temporary formation; and that the obliteration emanated from the walls of the vessel. Now let us look into this matter more closely.

Whatever may be the exact process which definitely repairs the damage done to the vessel, it is surely conceded by every one, that it can be completed independently of inflammatory action, and that the supervention of the latter may prove an obstacle to the completion of the reparative process.

It would, therefore, be very desirable that all of the measures which we may be called upon to employ be so used as not to excite inflammatory action.

The method which proves the least irritating and injurious will be the one most worthy of our confidence.

Now, if you critically consider these various methods of treatment for the arrest of arterial hemorrhage, you will readily admit, that every one adds to the injury already done to the vessel by division. Their action is entirely mechanical, having no regard to the process nature employs for the spontaneous arrest of the flow of blood. The ligature constricts the end of the vessel, so as to entail the death of the little piece on its distal side. It usually breaks the internal and middle coat, and must naturally be a source of irritation. The views which we entertain with respect to the possibility of development of phlogogenous substances in wounds, lead us to suppose that the ligature can readily become the nidus of that destructive agent. The string of silk and linen ordinarily used for ligature, with seton-like, imbibe fluids of the wound; decomposition of these, with development of minute animal and vegetable organisms, will necessarily result, and a source of local and general infection be produced. Metallic ligatures may not be open to this objection; but they constrict, and lead also to the death of a small portion

of the vessel, sufficient for disintegration and formation of septic matter.

Torsion twists and tears the various coats of the vessel; this must lead to modifications of nutrition, inflammation, and possibly also to the destruction of a certain amount of tissue. The same results must follow the use of the method of treating the artery by *refoulement*, *machures* or *applatissement*. The more modern improvements in these latter methods, as suggested by Drs. Spier and Stearns, are not exempt from these objections. Periplication, the method of Dr. Stilling, is very difficult of execution, and, for safety, too uncertain in its action. With acupuncture, the end of the vessel is not injured, yet it brings additional injury by the passage of needles, and does not command the confidence of the operator as regards safety.

The *acclusur* of Schmitz may be objected to for the same reasons.

It is unnecessary to detain you much longer with a minute discussion of the various disadvantages of these different methods of treatment known to our art. Diefenbach in his operative surgery recounted, over thirty years ago, many of these objections, and expressed the opinion that the profession was alive to the importance of the subject, and striving to perfect this part of surgical labor. He stated that some of the best men had made efforts to suggest improvements, but that the ligature, with all acknowledged deficiencies, had still maintained itself from the days of Ambrois Paré down to the present time. If we study the recent books and current periodical literature on the practice of surgery, we become convinced that the sentiment of Diefenbach still holds true, that the profession still feels the necessity of continued effort to devise means less liable to danger. I have had the opportunity of giving this subject considerable thought, and am now certain that we cannot hope for a realization of the object of these efforts, so long as any proceeding suggested entails additional injury and disregards the teachings of nature.

We should have a process of treating the divided vessel which would simply assist nature, not supplant her, by mechanically acting principles. The failure of nature to spontaneously arrest hemorrhage in larger-sized arteries is unquestionably due to the fact that they do not possess, for cogent physical reasons, sufficient muscular and circularly arranged fibres to bring about the contraction and diminution of the short axis of the vessel, and to effect longitudinal pleating, which we believe important, both for the evolution of the fibrinolytic agency and the security of the clot when formed. It does not seem probable to me that, other things being equal, the greater force of the blood, on account of the larger size of its column, should be the only reason why the spontaneous arrest cannot take place in a larger vessel.

We know that the muscular tissue of the middle coat, the chief contractile material, is not commensurate with the size of the vessel, that, in fact, as remarked before, it positively diminishes with the size of the vessel. There must be a reason for this; it cannot be accidental. It must find its explanation in the physical necessities of the circulation of the blood in large vessels.

Now, if this be correct, and if the want of sufficient contractile force is the cause of the non-arrest of bleeding, can we not rectify matters by simply doubling or trebling the amount of the circularly-acting tissue, by turning the end of the vessel inside out, as we would turn up the cuff of a sleeve? By so doing, we would obtain double or treble the amount of contractile force, and also furnish an equivalent for retraction.

I conceived this idea of imitating nature in the arrest of hemorrhage a number of years ago, and often expressed the same to former classes of students and to my private pupils; but the question naturally arose, whether it was mechanically possible to accomplish the process of turning over such small tubes as arteries.

With a view to the solution of the question, I looked around for some instrument to assist this mechanism. My first thought suggested a delicate-toothed forceps with which to enter the vessel up to the point whence the reflection should be made; then to take hold with it, and with another forceps to grasp the end of the artery, so as to enable me to slip the piece intervening between the first and second forceps over the fixed point at the first forceps.

Then, again, I proposed to use a single or double hook. Finally, in thinking over the various instruments which might be applicable or constructed for that purpose, I hit upon a little instrument invented by M. Lürer, of Paris, and called by him *fixateur à guîne*. Experiments on dogs soon taught me, that what appeared at the first glance so very difficult was quite easy. In fact, in trying the instruments which have been mentioned, I was astonished at the ease with which that turning of the end of the vessel could be accomplished. The experiments were performed with the assistance of my friend and former pupil, Dr. D. B. Smith. But another difficulty presented itself which then seemed an insurmountable obstacle to the realization of the object of our investigation, viz., the fact that after the reflection was made, the alternating distention and contraction of the vessel soon forced the reflection back to its original position. While, however, the reflection remained *in situ*, the quantity of blood oozing out was very small. We selected the iliac and the aorta abdominalis for these experiments,

FIG. 1 represents the arteriverter introduced up to the points where the artery is to be turned, with the double hooks extending a little beyond the cylinder.

and found that in the former it required about ten beats of the pulse before the vessel was straightened out again, while in the latter only about six were required. We also found that the *fixateur à gaine* was the instrument which accomplished the object most promptly without lacerating or injuring the internal coats.

Since making these limited experiments, I have made a number of attempts to test this principle of treatment on the human subject; but on account of the poor construction of the instrument I had to abandon my endeavors in that direction. Of late, however, the enthusiasm that I felt when first working out what I think is an important principle in surgical therapeutics has revived, especially since, with the application of the method of Esmarch which I have described to you, the possibility is given to make these experiments on the living subject without endangering the life of the patient. That you may understand fully the *modus operandi* of the method (which I propose to test in the case of amputation presently to be performed), I show you these illustrations. If this proceeding of treating arteries succeeds, I propose to give it the name of *arteriversio*, and the instrument the name of *arteriverter*. My distinguished friend M. Læer will pardon me that I make so free with an instrument of his invention.

FIG. 2 will give you an idea of the condition of the artery at the moment the end is reflected prior to the removal of the instrument. You can imagine that I enter upon this trial with a considerable degree of trepidation, remembering the difficulty previously experienced owing to the fact that the reflection would not remain in place, and that my *arteriverter* has not improved by occasional use. I hope, however, to overcome the first difficulty by making the reflection quite extensive, and, with a view of securing it in place, notch the vessel at the point of reflection, so as to enlarge it there, and thus offer an obstacle to its slipping back. If this should not prove sufficient, I propose to introduce immediately behind the point of reflection, a little delicate peg, made of the end of a number 12 English sewing needle, after the manner depicted in Fig. 3.

Should the contraction, after the reflection has been accomplished and secured, fail to instantaneously arrest the bleeding, I shall do that which we have to do occasionally in hemorrhage from capillaries and smaller vessels, viz., for a short time apply a digital compression to the end of the artery, while at the same time I shall prevent the blood from exerting its full force in the end of the vessel.

With this I expect to obtain a temporary clot which will answer the purpose. Should we have the good fortune of realizing that the possibility and practicability of this treatment will be demonstrated, there will then be ample room and occasion for further study.

With these hasty remarks we will leave the discussion and proceed to the performance of the operation.

At this juncture the patient was brought in, and after being placed under the influence of ether the operation was performed in the manner above indicated, the division of the muscular structures falling in a line a little above the union of the upper third with the middle. The bandage and elastic tourniquet of Esmarch prevented any loss of blood save possibly

that of a dozen drops. Two muscular branches were secured by ligature, but the femoral was treated in the manner described. Although the instrument used was poorly made, the little hooks not being placed in a direction such as to enable them readily to be hooked into the walls of the vessel at the point of reflection, yet the act of turning was comparatively easy. After the reflection had been made, the tourniquet was loosened sufficiently to allow the pulsation of the vessel to be seen, when a fine spiral stream of blood escaped from the artery *per saltum*. I then notched the vessel, by means of a pair of fine scissors, at each end of a transverse diameter. The notch was made through the two walls—the main wall and the reflected—and, commencing at the point of reflection, extended about two lines in a longitudinal direction.

Owing to the contraction of the circular fibres after division, a wedge-shaped gap was formed at each notch, so that the circumference of the vessel at the edge of reflection was increased. This caused the reflected piece to appear to surround the end of the vessel more closely, in fact to constrict it. These steps of the experiment were made with the stump almost extended. While in this position, an irregular spurt of a small spiral stream of blood was observed whenever the blood was allowed to be driven into the artery by the full force of the circulation. When, however, the stump was flexed at right angles with the body, no such spurting took place. Fearing that hemorrhage would not entirely cease, and appreciating the debilitated condition of the patient, I felt it necessary to guard more thoroughly against any sudden loss of blood. I therefore introduced, immediately behind the points where the vessel had been notched, two of the little pegs which I described before. They were placed so as to cross each other at right angles. On account of the remarkable retraction of the surrounding muscular tissue, and owing to the fact that it required considerable manipulation to make the *arteriverter* work, the vessel was quite prominent, and not withdrawn into the surrounding tissue. This enabled me and those present to become convinced that the vessel, after the application of the pegs, was hermetically sealed; for notwithstanding that the full force of blood was pumping against the end, so as to raise and depress it with every wave, not a vestige of blood escaped. The wound was allowed to remain open, in order to give an opportunity to study the process of repair.

At the end of about half an hour, the patient having been placed in bed and the stump supported by compresses, one of the pegs was removed. For nearly forty-eight hours the vessel moved with every pulsation; yet, on applying the sense of touch, no dilatation could be felt within over an inch from the end of the artery, and I felt justified in supposing that the artery was well closed by clot. Gradually the wound became covered with granulations, which increased until the stump of the vessel was completely removed from view.

The process of repair was tedious, as was to be expected from a constitution like the one we had to deal with. The patient finally recovered, however, and at the present writing enjoys a fair degree of health. I am unable to state what has become of that little peg.

Since the performance of this operation I have had the opportunity of employing this method in three cases. The first was an amputation immediately below the shoulder-joint. The brachial was treated by simple reflection and one peg. The patient had been an intemperate man; and fearing the develop-

ment of dilerium tremens, I thought it best to apply the peg in addition to the reflection, although this alone closed the vessel. The patient died of septi-cæmia on the twelfth day, and upon making a post-mortem examination, I found the entire wound in a gangrenous condition, and yet the artery nicely closed by a thrombus of an inch and a half in length, presenting its characteristic form, and having already entered at several points into firm connection with the tunica intima.

The second case was an amputation of the leg through the middle third, where the anterior and posterior tibials were treated by simple reflection and one peg. The peg, which was passed through the anterior tibial, was removed within twenty minutes. This patient recovered rapidly, without the slightest untoward occurrence. Three days ago it was my privilege to try this method again on the femoral, after an amputation through the middle third by my friend Professor Holliday, of the Cleveland Medical College. The artery was reflected, one peg inserted, and the bleeding instantly arrested. During all these trials I labored under the embarrassment and difficulties naturally resulting from an insufficient instrument. On account of the poor quality of the hooks, the instrument failed to take hold readily. Repeated attempts had to be made before I succeeded, and it is reasonable to suppose that in these attempts the various coats, more especially the brittle internal and middle coats, were more or less injured, so that their contractile power, by which the cross section of the vessel could be diminished, was considerably lowered. Whenever the hooks took hold properly, the mechanism of turning the end of vessels, large or small, upon itself, was quite easy. In fact, my experiments on dogs have convinced me that that part of the method will be unobjectionable. I have experimented with very small arteries of dogs, and find that they can be turned inside out as easily and as promptly as the larger ones. I have the assurance of Mr. Stohilman, senior partner of the firm of Geo. Tiemann & Co., that the little instrument which seems to be best adapted for the purpose of turning the vessel, can be constructed so as to promptly take hold at any point desirable; and at the present time he is constructing a number of these instruments in proper sizes, to correspond with the different calibres of the arteries which have to be treated.

Judging from the experience that has been gathered by me in regard to this subject, I feel justified in expressing the opinion that this method of treating arteries is a justifiable proceeding, and that it is practicable in a large number of surgical operations. I also entertain the hope that whenever the reflection is easily and skilfully performed by the proper instrument, the reflection alone will be sufficient to arrest hemorrhage, and that perhaps only in the largest arteries it may be necessary to add one little peg. The success of the trials which I have made seems to me sufficient to justify my bringing this subject to the attention of the profession.

I have taken the liberty to call this method new, from the fact that the literature of the subject, as far as accessible to me, does not mention a single idea pointing to the principle involved in it. If it has been my misfortune to overlook the labors of the past and present in this direction, I shall be most happy to give credit where it properly belongs, and renounce all claims of priority. In either case, I beg leave to urge upon the profession a careful investigation and study of the subject.

87 PROSPECT ST., April 15, 1875.

Original Communications.

REMOVAL OF A PIN FROM THE DEEP URETHRA.

BY E. L. KEYES, M.D.,
NEW YORK.

IN the MEDICAL RECORD of March 6th, 1875, I communicated a case, with some remarks, on the removal of rounded foreign bodies from the urethra, by means of Thompson's divulsor, and ventured to predict success for the instrument in its wider application as a forceps.

The following case is in point, and the brilliant result which attended the use of the same instrument in extracting one of the longest and sharpest of the foreign bodies apt to find its way into the male urethra, justifies the publication of a note upon the subject before the memory of the older case grows cold.

* * * * *, a young man, was sent to me at my office, on the morning of April 16th, by a physician, with a note, stating that he (the patient) believed he might have a pin in the urethra. The doctor had found a stricture of large calibre at four inches, and, with a steel instrument, felt something gritty, which he believed might be a pin or a calculus, "at five or six inches."

The patient's story was that he had been troubled in voiding urine for some time previously, and on the night of April 15th, while under the influence of liquor, had found himself unable to pass water at all; that he had consequently introduced a pin, head-foremost, into the urethra, and "thought it might have dropped in;" that his retention was relieved later in the evening by a physician, who passed a catheter, and that on the following morning (April 16th) he had applied to the physician who sent him to me.

Examination of the urethra externally failed to detect anything feeling like a foreign body. Pressure on the perinæum caused pain, but not a sharp pain, as of pricking.

I passed a long whalebone filiform guide, and distinctly felt the grating against a foreign body in the deep urethra. Upon the guide, Thompson's divulsor (tunnelled) glided smoothly into the bladder. The blades were separated widely, and were then again approximated, the entire instrument being rotated over about a quarter of a circle back and forth while the blades were approaching each other, as I believed this manœuvre well calculated to catch a pin.

On withdrawing the divulsor, closed, the pin was found within it, at a point corresponding to 5½ inches from the meatus. The pin was a stout brass one, 1½ inch long, and came out point foremost, but lying snugly between the hollowed blades of the divulsor, its point unable to catch the urethral walls.

The gratification of the patient may be better imagined than described.

An ordinary forceps would have encountered great difficulty in catching this foreign body in such a manner that the point would not have lacerated the urethra on its way out. The pin could not be felt from the perinæum or the rectum, so as to have its point pushed through the integument, and then to be forcibly extracted by Dieffenbach's* method; and had it reached

* Ueber fremde in die männliche Harnröhre eingedrungene Körper. Casper's Wochenschrift, 1. 1843.

the bladder, a stone and subsequent lithotomy would have been the least bad results—in short, it is hard to conceive of a method better adapted to such a case than the one used, and therefore it is now justifiable to extend the probable applicability of the divulsor as a forceps to the extraction of all foreign bodies from the urethra, long and sharp as well as rounded.

PERITYPHLITIC ABSCESS.

By P. B. PUMYEA, M.D.,

IMLAYSTOWN, N. J.

IN the MEDICAL RECORD of April 17th, a case of perityphlitic inflammation is reported, which resulted in suppuration and, fortunately, in recovery.

My experience in the treatment of three cases, so similar in symptoms, and so dissimilar in the progress and result of the inflammation, has been so different from Dr. Pooley's that I am induced to place an abridged report upon record.

On Sept. 19, 1873, a boy *æt.* 13, previously and now in good health, came to my office complaining of pain in his back, side, and right hip-joint, and with a tender tumefaction in the right iliac fossa. This tumor was disconnected with the abdominal walls, as they were freely movable over it.

The tumor continued to increase in size and the tenderness and constitutional symptoms to grow worse until the 24th, when vesication was produced over the site of the tumor.

On the 26th, only the second day subsequent to the application of the blister, I was equally surprised and gratified to find the tenderness much diminished and him much improved in appearance and feelings. From that date, his convalescence and the disappearance of the tumor were continuous and rapid.

On July 15th, 1874, I was called to see a young lady who had just had an attack of cholera morbus. Although the pain had subsided, the nausea and vomiting still continued, and subsequently the stomach became so irritable that all medication and nourishment had to be given per enema.

A few days after my first visit, my attention was directed to a pain in her right side, and on examination, a perityphlitic tumor was discovered. A blister was immediately applied and, although the effect was not so marked as in the other case, still its efficiency was very appreciable and significant. Owing to the gastric irritability before mentioned, convalescence was slow, but no suppuration ensued, and she made a good recovery.

Again, on Feb. 10th, 1875, I was called to see a boy *æt.* 14, with a pain in his side. On my arrival, after patiently listening to several volunteered diagnoses, I found his abdomen swollen and tympanitic, and particularly tender in the right iliac region. By firm pressure and gentle percussion in that situation, I found there a circumscribed solidification and made the diagnosis of perityphlitic inflammation and consequent peritonitis.

I ordered turpentine stupes and gave opium; but no improvement was effected, until a blister was applied, which again speedily established convalescence and confirmed my belief in the efficacy of vesication in such cases.

During his sickness, I was informed that he had had an attack of the same kind before, and the doctor had then told his mother that, if she had given him a dose of castor oil, before he was called, that he would not have been so bad. She, acting upon that suggestion,

had given him two doses of *ol. ricini* before I was sent for.

If I were asked to formularize the treatment in such cases, I should emphatically say *avoid* cathartics, apply a blister externally, and give opium *p. r. n.* internally.

Progress of Medical Science.

ANTISEPTIC JAPANESE PAPER AS A DRESSING FOR WOUNDS AND ULCERS.—At a meeting of the Clinical Society of London, held February 26, Mr. Callender presented some specimens of Japanese paper that had been prepared with antiseptic solutions in two ways. The first method was with a solution of salicylic acid and mastich. He took of salicylic acid forty grains; mastich, sixteen grains; rectified spirit, one fluid ounce; he then dissolved the mastich in the spirit, added the acid, and shook the whole until it was dissolved. The second method was by a solution of carbolic acid and mucilage. He took of carbolic acid one ounce; mucilage of acacia, one ounce; water, twenty ounces; he dissolved the acid in the water, added the mucilage, and mixed the whole. The strength of this solution, he thought, might be varied, but it was desirable to prepare it of a greater strength for keeping than for immediate use; first, to allow for the loss of carbolic acid from evaporation; and secondly, to permit the dipping of the prepared paper in water before it was applied as a dressing, a process which necessitated some further dilution of the acid. The mastich and the mucilage were added to increase the softness of the paper. Two sheets of paper were placed together, saturated with either of the solutions; they were then rapidly dried and preserved in tin boxes. They might be applied, as ordinary lint, either wet or dry. Ointments could be spread upon the paper, and Mr. C. thought that it was well adapted for use in various skin affections where such medicaments are needed. One advantage that it had was its cheapness as compared with lint.—*British Medical Journal*, March 6, 1875.

INFECTION BY CADAVERIC POISONING.—It is generally thought that infection by cadaveric poisoning only takes place where there are lesions of the integument, and especially when these are recent. Some authors, such as Neumann, Cohnheim, and Hueter, have, however, proved apparently that the introduction of putrid agents may take place through the glands of the skin, in the same manner that certain medicines externally applied find their way to the interior. The glands of the skin differ in this regard and the sudoriporous glands have this property to a much less extent than the others.

The first observations of M. Odenius were made some time since; his attention was called to the subject by the occurrence of several pustules on the back of his hand and wrist, two or three days after making a post-mortem examination, when there had been no abrasion of the skin. These pustules always had a hair in the centre. The cause was found to be the use of rancid sweet oil for smearing his hands before making the examination. There were no pustules when he used no oil. Subsequent analogous observations caused him to suspect that cadaveric poisons might enter the system in the same manner. This suspicion was confirmed by an accident in 1871. Having made an autopsy on a fresh subject, dead of pneumonia, a painful swelling appeared the next day on the volar surface of the

forearm. There had not been the slightest lesion of the surface, but during the dissection a little matter from the cadaver had run down upon the arm and dried at the wrist. The affection terminated by the mortification of the diseased parts. Movements of the muscles of the hand and forearm caused chills, which were attributed to the introduction into the veins of pyogenic matter from the inflamed parts. The lymphatic glands and vessels were not attacked, the axillary glands alone excepted.

Similar phenomena were subsequently observed by the doctor under similar conditions in other persons. He had also observed that the same accidents happen to accoucheurs after prolonged obstetrical manipulations.—*Nord. Med. Ark.*, vi., 7.

LEPTUS AUTUMNALIS.—In Thisted, a small village of Denmark, an epidemic occurs every summer, which is called by the inhabitants *Augustknuder*, or, "August-buds." The disease makes its appearance regularly at the end of July, and continues until the first of September. It is characterized by an exanthem, which usually appears on the forearms and neck, and is at first papular, then vesicular and pustular, and is characterized by intense itching. It is most frequently observed among persons who work in gardens.

Dr. Heiberg, suspecting the cause of the malady, made a number of ineffectual researches, when at last he had an opportunity of examining a patient whose skin, in consequence of a cerebral affection, was in an almost anæsthetic condition, and she had not, therefore, scratched the skin. In the centre of the papules, he discovered some red points which, examined under the microscope, were recognized as the *leptus autumnalis*. Gudden distinguishes two forms of this larva; the larger one is yellowish, the smaller red. He thinks the former is destined to become the female, and the latter the male. All the insects discovered by Dr. H. belonged to the second category. The development of the insect is still unknown. Kraemer has observed it on two moles, a field mouse, and a bat. Dr. H. thinks its presence was only accidental on these animals, as well as in man, the larvæ not finding there the conditions favorable for their ultimate transformations. It is thought, however, that these neutral larvæ need to live on the body of some warm-blooded animal in order to accomplish their metamorphoses, and the author is of the opinion that they usually attach themselves to birds, the latter offering the most favorable conditions for the further development of the insect.

This disease has also been observed in Versailles.

As a prophylactic, lotions of the alcoholic extract of *Pyrethrum caucasicum* flowers are recommended. Should the disease become developed, the same remedy will also relieve the itching, and cause the exanthem to disappear.—*Nord. Med. Arkiv.*, vi., 25.

NUSSBAUM ON CANCER.—Prof. Nussbaum of Munich thus formulates his views on this subject: 1. Cancer is a proliferation of the epithelium; it extends rapidly and displaces the connective tissue stroma, ulcerates from slight causes, causes destruction locally, affects the patient deeply by suppuration and hemorrhages, and ultimately diffuses its particles through the whole body, causing like proliferation and destruction in various organs, and in this way death. 2. Advancing age, grief and care are to be regarded as among its causes, while all structures in which there is a disproportion between the epithelium and connective tissue, such as warts, scars, glandular nodes, etc., predispose to its formation. Such parts also are especially liable to it which are often irritated but never acutely inflamed. Cancer is not congenital or inoculable. It is

at first a purely local disease and the general system is involved by infection from the original focus. 3. The relapse of cancer after operation is either by continuity of cancerous elements which have been left behind; or from neighboring diseased tissues already predisposed to cancer which have been left behind; or a relapse may occur from the transportation of cancerous particles which have found their way into the circulation and have been thus disseminated. 4. Cancer can be radically cured by early and extensive operations. 5. According to full statistics, patients who are operated on live decidedly longer than those who have not submitted to treatment. 6. All remedies which act upon the tissues, the blood or the nerves, may deserve consideration. Early and thorough operation, however, stands at the head of the list.—*Verst. Int.-Bl.*—*Allg. Med. Centr.-Ztg.* Mar. 27, 1875.

LOCAL EFFECT OF ICE ON ANIMAL TEMPERATURE.—Schultze, of Heidelberg, in an article on this subject in the *Berliner Klin. Wochenschrift*, has tested the effect of ice on the deep-lying organs by performing a series of experiments on dogs. The hair was shaved from the belly of the animal, and an ice-bladder, the size of which was in proportion to the weight of the body, was applied. A Haidenbain's thermometer was inserted through an incision into the abdominal cavity. After reading off the diminution of temperature produced by a prolonged action of the ice, the animal was killed by chloroform, and the relative depth of the mercurial cylinder determined. It was found that at its deepest position a diminution of 2¼° F. was the maximum produced by the application of ice for one hour, and a limit was found to this diminution which was not exceeded by a longer application.

Other experiments, in which several thermometers were introduced to various depths, showed that the diminution of temperature was lessened in proportion to the distance from the surface.—*Ugeskrift f. Læg.*, Nov., 1875.

RETAINED PLACENTA.—In reference to some cases of retained placenta that had been treated by forcible removal, which he regards as a dangerous practice, Dr. Linéard, of Caen, calls attention to the fact that many years ago he published a simple procedure, which he has always found as effectual as it is safe and easy, and which is also a very efficacious means for the prevention of after-pains and uterine hemorrhage. It consists in the injection of the umbilical vein with cold water. A clean section should first be made, so as to bring the vessel plainly into view, and also to shorten the cord, which should not be more than from twenty to thirty centimetres in length. A syringe, containing at least 150 grammes, and having a long fixed canula, should be employed. The colder the water used, the less is the quantity that need be injected; so that while 150 grammes suffice at the ordinary temperature of winter, twice or thrice as much may be required in summer.—*Gaz. des Hôp.*, February 25.

TINCTURE OF IODINE FOR CLOASMA UTERINA.—Dr. Dubois recommends this method of treating the unsightly patches that so frequently disfigure the faces of pregnant women. Every evening a coating of the tincture is to be applied to the spots. The epidermis exfoliates and the spots disappear. If this does not follow the first application and some pain results, he then suspends the use of the iodine and replaces it with cold cream. Then, when the epidermis is newly formed, he recommences the use of the iodine, and this time the patch will disappear entirely.—*Gaz. Hebdom.*

THE MEETING OF THE AMERICAN MEDICAL ASSOCIATION.

THE next meeting of the American Medical Association will be held in Louisville, commencing the first Tuesday in May. The attendance will doubtless be reasonably large, and the sessions, it is to be hoped, will be profitable to all. The new plan of organization which went into effect last year worked in a very satisfactory manner to all interested in the welfare and continued prosperity of the Association. The establishment of a Judicial Council, to which all vexed questions of an ethical character are to be referred, was a very necessary step to be taken in view of the unenviable notoriety which this Association had gained as a quarrelsome body. During the session at Detroit there was not a single circumstance which occurred to mar the harmony of the meeting, nor to create any of those individual misunderstandings which are so apt to take place in large and promiscuous gatherings. From this last meeting, the Association takes a fresh start towards extending the usefulness and enlarging the influences which justly belong to such a representative body.

All the elements exist for making the coming meeting a memorable one socially and scientifically. The sections have been well provided with representative men as chairmen, and there is no reason why the meetings of these branch societies should not be profitable to all concerned. In fact, as much care is now taken in the selection of these chairmen as in the choice of our President of the Association, for in reality the officers are to be recruited from the ranks of the former. And after all, the real strength of the Association should rest in its capability for doing scientific work. This certainly tends to make it attractive to the workers in the profession, and will do a great deal towards bringing together a larger number of first-class men.

At the last meeting the sections were better attended

than at any previous time within our recollection. This was not only explained by the care exercised on the part of the Committee of Arrangements, in having rooms for the respective meetings conveniently arranged, but by a desire which the profession has for scientific improvement, and by a disposition which it always evinces to profit by opportunities whenever they are offered. There was no lack of material for discussion at the different sections, and in the main the material was good. That there were exceptions to be taken to some of the papers every one present at these sessions is willing to admit. The fact that any paper of indifferent merit should have been allowed to come before the sections is an argument in favor of the adoption of any reasonable plan to prevent such a thing in future. We have already a starting-point to some proper regulation in this matter in the chairmen of these Associations, whose duty it is to see that proper papers only are presented, and who are empowered to solicit contributions from representative men all over the country. But such a plan followed out too absolutely would be unfair to many who might not be invited, but who might nevertheless have some valuable information to contribute. That is to say, those gentlemen who had been authoritatively invited would have the preference over those who were not so favored, and would inevitably crowd the latter out. In view of this difficulty, it strikes us that it would be eminently proper to vest the authority of the selection of papers to be presented in a committee, whose duty it should also be to decide upon the time to be occupied by each author, so that all could have some sort of a hearing. This is the work of a business committee of the Medical Society of this State, and has always been performed to the satisfaction of every one who has any subject to present or any special communication to make. If each section could have such a business committee all the really good papers could be read, either as a whole or in abstract, and much valuable time saved by the rejection of all those articles which have no practical bearing or scientific interest.

The regular publication each day of the reports of the sections could not be made as promised at the last meeting, but in its stead very accurate accounts of the meeting were furnished by the Detroit press. And after all, this is probably the only way that the reports can be satisfactorily made, without saddling the Committee of Arrangements with a more than onerous task, and without incurring a good deal of extra expense to the Association. When the reports appear in the daily papers they are always prompt, and readily accessible to all the members. The only improvement we would suggest would be, that one of the leading papers should be selected by the Committee of Arrangements as the official organ, with the understanding that everything in the shape of a report of the proceedings of the Association in the section should first receive the sanction of said committee before it should be published. This would remove

any objections which might be urged against individual advertising.

The selection of a President of the Association for the coming year will be upon a comparatively new plan. In accordance with previous instructions, the State Societies, in selecting their delegates, head their list with the one who is to be member of the Nominating Committee. The majority, if not all, of the members of the Nominating Committee so selected are good men, who will doubtless be prepared to act independently. There is no doubt that the selection of President will be made from this State—either from New York city or from Rochester. From present appearances, and from what we know of the desires of the majority of the delegation, the gentleman from the latter city has the best chance. In any event, however, the choice will be a good one.

And now, in conclusion, speaking of the social element of the meeting, we cannot say too much in prospective. The surroundings of Louisville are the most beautiful in the country, and the inhabitants of that city have a reputation for hospitality which is unequalled anywhere. We have no doubt that social entertainments will be abundant, but of all that can be promised, none can, in our opinion, equal in interest and enjoyment a visit to the Mammoth Cave, to which we understand the members of the Association are to be invited by the Committee of Arrangements.

Stated Meeting, April 15, 1875.

DR. S. S. PURPLE, PRESIDENT, in the Chair.

THE RELATION OF THE URINE TO DISEASES OF THE SKIN.

DR. L. D. BULKLEY read a paper upon the above subject, in which he illustrated the application of physiological chemistry and chemical pathology to the study of diseases of the skin. Many of these are supposed to be entirely local, others partly nervous, and still others dependent upon dyscrasia. How far these diseases are dependent upon deranged blood-current it is impossible to say, but it is highly probable that such derangements, indicated by fever developments during their continuance, greatly aggravate their symptoms. His remarks were chiefly made upon eczema, acne, psoriasis, urticaria, ichthyosis, and purpura; and with the view that the urine is an index of the blood state. That skin diseases of this nature are of constitutional origin is not a new matter; but for a long time it has engaged the attention of observers, particularly of the French school, and it is to them that we are indebted for knowledge upon what is called the arthritic diathesis. The application of this diathesis, however, has been too limited upon the one hand and too positive upon the other.

The physiological relation between the skin and kidneys has been long recognized, such as the coexistence of a dry, harsh skin with kidney disease, etc.; and we may well expect that there will be some changes of the blood in diseases of the integuments, and that the kidneys will show these relations in a definite manner through the urine. His experience had verified such conclusions, and had taught him that there is a close relation between the kidneys, and secretions of the body, and the state of the skin.

With regard to the changes observed in the urine, in the course of febrile affections, he was of the opinion that our present knowledge of the nature of fever is too limited to enable us to decide whether the alterations in the urine are the result of the febrile state or not, and therefore he included the febrile exanthemata in the present consideration.

His analysis of the urinary secretions began in 1867, and has included 535 examinations made of the urine from 161 patients. A portion of these examinations were made by his assistants, under his direction, but personal observations were made and recorded in 253 analyses from 79 patients. These were confined mostly to diseases distributed as follows: eczema, 33; acne, 15; psoriasis, 8; pruritis, 6; miscellaneous, 17. He based the changes which are found in eczematous patients upon 113 observations, and divided them into two classes: 1. Those indicating acid dyspepsia, with varying quantity and specific gravity of the urine; there may be persistent, abnormal acidity, with high specific gravity. 2. Those in which there is a uric or lithic acid diathesis; when a chronic lithæmia exists; or when the urine is not only acid, but almost, if not always, deposits urate, or free uric acid.

In *acne* his own observations alone were given, and they were, that the urine in this affection is usually acid; average specific gravity, 1023½; and the urinary changes are more commonly those of dyspepsia, including urates, uric acid, etc., and the presence of an abnormal amount of phosphates. The observations made and reported, in the main, corroborated those that have been given by Garrod, Bence Jones, Prout, Fox, Wilson, Murchison, Bamberger, Simon, Heller, Martin, Johnson, Schlossberger, Marcet and others. He regarded the urine as a most important element in the study of dermatology, for in not one of the skin diseases considered was the urine found normal, and in many instances the pathological changes were clear, and immediately involved important considerations in treatment.

The association of urinary derangement with diseases of the skin was regarded as an indication of systemic disturbance, and it is useless to use remedies while these conditions are present. The results of therapeutics also indicated a close connection between digestive derangements and skin diseases, hence he could not subscribe to the doctrine that they are chiefly of local origin, but that many of them are of constitutional origin, and that our therapeutics should be governed accordingly.

DR. W. H. DRAPER remarked at some length upon the theories presented to the profession some twenty years ago, by Bence Jones and Garrod, relative to the changes that take place in the carbonaceous and nitrogenous elements which are introduced into the system through the food, and thought that a careful consideration of these should enter largely into our study of tegumentary lesions and their manifestations.

He did not think that the urinary changes seen in the course of the exanthematous fevers were anything more than those dependent upon the fever itself.

DR. R. W. TAYLOR was of the opinion that lesions

of the skin could not, in all cases, be explained by the condition of the urinary secretion. He regarded the effect of the German teaching as beneficial in modifying the doctrines advanced by French observers under the name of various diatheses, to which it was supposed all skin diseases were due. He also regarded these diatheses as summed up in "errors of assimilation," referred to by Dr. Draper; also that English and American physicians have gone still further and placed this question upon a scientific basis; and also, that when we shall combine our observations in this direction with those made by the Germans, we shall have arrived very nearly at the truth of the matter. The urine will give therapeutical indications of value, but these cannot with safety be regarded as the only indications; for the skin may, and is likely to undergo inflammatory changes without any diathesis at the root of it, and hence it is that we should give credit to the Germans for their observations in this direction. It is not well, however, to carry this view to an extreme, but we should take into consideration, while studying these lesions, the fact that the skin has an inherent ability to undergo inflammation independent of any constitutional cause.

NEW YORK MEDICAL AND LIBRARY JOURNAL ASSOCIATION.

Stated Meeting, April 23, 1875.

DR. E. R. PEASLEE, PRESIDENT, in the Chair.

ON OPIUM POISONING.

THE paper read by Dr. Andrew H. Smith upon this subject was confined chiefly to the consideration of the effects of the drug, which shorten the life of the patient or cause solicitude to the practitioner. In some cases the symptoms of themselves are insufficient to make an absolute diagnosis, yet they are generally so distinctly marked and peculiar that, with the history, if that can be obtained, they leave but little room for error in this direction. The first effect of the drug is to produce more or less stimulation or excitement, which is followed by giddiness and a sense of oppression, and soon by extreme drowsiness. At this stage nausea and vomiting may occur. If the patient is permitted to sleep, it deepens into a profound unconsciousness, the lips and face become more or less cyanosed, the breathing becomes stertorous—in short, the patient falls into a condition indicating the advanced stages of opium poisoning. The pulse, which at first may have been bounding, now becomes slow and full, but later on small, feeble, and thready. The pupils become closely contracted and insensible to light, deglutition ceases, mucus accumulates in the air-passages, and death takes place from asphyxia. Convulsions may occur, especially in children. The intellect is usually almost completely overpowered.

One of the most constant symptoms is contraction of the pupil, and this is due to the effect of the drug upon the nerve centres which govern its movements.

This symptom is of great value. The contraction is usually symmetrical, and in this respect differs from that induced by irritation of the membranes of the brain, in which case the pupil seldom contracts equally. It sometimes happens, however, that the pupil contracts unequally in opium poisoning, so this symptom should not be relied upon too absolutely in making out a diagnosis, and should not be accepted as diagnostic unless there are other symptoms to sustain it. It is to be borne in mind that in the last stage the pupils generally become widely dilated.

The respiration usually diminishes in frequency. The general opinion is that opium destroys life by interfering with this function, and it is the effect which the drug has upon the respiration that has been held as a criterion in deciding whether danger is present or not while administering opium in the treatment of disease, especially peritonitis. The rule has been established by Prof. Alonzo Clark, and has been followed by the profession in general, that the opium is to be continued until the respirations are brought down to twelve to the minute, unless the important symptoms of the case are relieved before this point is reached; but when this point is reached in any case the remedy is to be discontinued, except in such doses as are just sufficient to hold the respiration.

It must be borne in mind, however, and this is a point of great importance, that the most dangerous narcotism may be present while respiration is going on at or near the normal rate. The fact that such cases can occur renders it absolutely necessary not to rely upon the respiration alone as a criterion to guide us in the administration of the drug.

The contraction of the pupil and the general condition of the patient should serve to place the practitioner upon his guard, although the respiration may be only slightly affected. The changes which occur in the pulse are more tardy in making their appearance than are the corresponding changes in respiration. *Post-mortem* appearances after opium poisoning are almost negative. If the opium has been taken in a liquid form there are seldom any traces of it to be found, but if taken in a solid form the opium itself may be seen. The alcohol in laudanum, if that is the preparation used, may cause some hyperæmia of the mucous membrane of the stomach. The lungs are sometimes found engorged, as well as the right side of the heart.

Extravasations of blood in the brain are rare. There are no specific lesions left by opium poisoning.

Diagnosis of opium poisoning from *apoplexy* is sometimes difficult, especially in those cases in which the patient is found in a comatose condition, and no history can be obtained. In a large proportion of cases the two conditions may be distinguished by means of the following symptoms: In *apoplexy* the pupils are rarely contracted equally; in opium poisoning almost always contracted equally. In *apoplexy* there is no possibility of arousing the patient, but you can usually induce reflex movements. In opium poisoning the patient can generally be aroused for a moment, but reflex movements cannot ordinarily be induced. In *apoplexy*, if the patient is carefully watched, and any movements occur, it will be seen that they are restricted to one side of the body; and if no movements are made, there is present a condition of relaxation affecting one side, which can generally be easily recognized.

In *apoplexy* the breathing is commonly stertorous, while in opium poisoning it is rarely stertorous. In *apoplexy* pulsation in the carotids can be seen, while in poisoning from opium these are not observed. These are the more prominent symptoms by which the two conditions can be distinguished. In many cases the opium can be detected in the breath.

Uramic coma sometimes makes its appearance without preceding dropsy, and may look like opium poisoning; but it lacks the characteristic pupil, and the urine will be found to contain albumen or casts, or both.

Alcoholic intoxication is a condition that must be separated from opium poisoning. In this case the pupils are not contracted, and the alcohol can gener-

ally be recognized in the breath. The drunken man, when aroused, begins to babble incoherently, while the man suffering from opium poisoning at once lapses into his sleep again. The two conditions may be associated, and then it becomes a case difficult of diagnosis. Prognosis is extremely favorable if treatment is properly employed. He had rescued one patient in whom the respirations went as low as one in two minutes. Patients have been restored who have taken five, six, and eight ounces of laudanum. While there is any sign of life, efforts at resuscitation should not be relaxed. Opium is seldom administered with felonious intent. It could scarcely be given without the knowledge of the person on account of its bitter taste, and its effects are so obvious that the fact would be at once recognized by the victim himself. A person in severe pain, or laboring under great cerebral excitement, will bear a much larger amount of the drug than when the system is in its normal condition; but when the pain and wakefulness are overcome, the system is deprived of the protection thus afforded, and now, if more of the drug is given, alarming and perhaps fatal narcosis may be induced. It is in this way that the sudden narcotism is to be explained which occasionally supervenes when only doses of ordinary size are continued that have previously been tolerated without the development of any alarming symptoms. The system has lost its power of protection, and succumbs rapidly.

The treatment of opium poisoning consists in the evacuation of the stomach, the administration of such drugs as are supposed to have the power of modifying the effect of the poison, and the use of various agents to arouse the nervous system, the respiration, the circulation, and the temperature.

As emetics, mustard, alum, sulphate of zinc, and sulphate of copper may be used. Tartar emetic should never be employed, and ipecac is too slow. When a considerable degree of nausea exists sudden pressure upon the epigastrium may induce vomiting. Emetics are apt to fail when the narcotism is extreme, and then the stomach-pump may be used. In absence of this instrument a piece of ordinary india-rubber tubing may be used, after the manner of a syphon. For arousing the patient various measures may be resorted to already well known, but electricity is by far the most serviceable when a battery is at hand. The faradic current, and perhaps very powerful, should be employed, and it may be applied to all parts of the body. The weakest current should be used that will provoke muscular contraction. Of the means for restoring respiration, artificial respiration and electricity are the most important. The electricity may be applied to the phrenic nerves, an inspiration induced, and this repeated fifteen or sixteen times a minute. The negative pole always excites a stronger action than the positive, and metallic electrodes are much more efficient than sponges. By means of this agent some desperate cases have been saved when all other means have failed. It must be borne in mind, however, that muscular contraction can be exhausted by too free application of the battery, and such exhaustion must not be mistaken for symptoms of increasing narcotism. Oxygen gas is a very efficient agent. When the respiration is very slow artificial respiration must be kept up at the same time the gas is administered, in order to get sufficient amount into the lungs to act upon the blood. It stimulates the capillary circulation and thereby aids in relieving the right side of the heart. We have no chemical antidote for opium; nor have we any complete physiological antidote, but we have two agents which may be used with great benefit.

These are coffee and belladonna. It is only within the last fifteen or twenty years that any practical results have come from the use of belladonna, and regarding its influence, how it acts, when it is to be administered, and when discontinued, etc., he quoted quite extensively from the paper of Dr. Mary Putnam Jacobi, published in THE MEDICAL RECORD in the year 1873, in which she forestalled the report of a special commission appointed in Great Britain, with Dr. Hughes Bennett at its head. Attempts have been made to fix the amount of atropine sufficient to counteract the effects of the opium, but for obvious reasons this cannot be done. We must be guided by the degree of narcotism present, and can only judge of the amount of atropine to be given by continuing it in tentative doses until the pupils begin to dilate. It is commonly used hypodermically in from $\frac{1}{30}$ to $\frac{1}{40}$ grain doses. The danger has not passed in a case of opium poisoning when consciousness has been restored, but the liability to relapse should make the physician watchful until reaction is fully established, and circulation restored to something near its normal steadiness and volume. But even then there is ulterior danger from consecutive pneumonia, consequently great care should be exercised and every precaution taken to prevent such a sequel. Three cases were reported which illustrated the fact that dangerous narcotism could be induced, while the respiration remained nearly of normal frequency.

In one case the respirations stood at twenty to the minute, and yet the patient was dangerously narcotized. (It was not stated whether there was any evidence of kidney disease or not in these cases.)

A third case was reported in which dangerous narcotism was induced by applying a solution of morphine to a wrist-joint which was the seat of synovitis. The skin was intact. Several cases were reported in which the symptoms of danger were extreme, but the patients had been restored by resorting to the means already mentioned.

DR. BAYLIS reported a remarkable case in which the patient, a gentleman 40 years of age, had suffered from two attacks of pleuritis. The general condition produced by these attacks was one of restricted lung action and labored heart action. Within three and a half hours he took 150 ℥ of Magendie's solution (Squibb's), but was not overpowered until six and a half hours after taking it. Profound somnolence continued for eighteen hours; partial somnolence between two and a half and three and a half hours, but he did not recover his mental faculties until twenty-two or three hours after taking the drug. When he did recover his mental faculties he was irritable and cross, which was entirely contrary to his usual disposition. In this case there was pulsation of the carotids. The treatment consisted in the use of atropine, electricity, oxygen gas, injections of beef-tea and brandy, guided with regard to frequency according to the condition of the pulse, external warmth, rubbing, etc., systematically and persistently continued. His respirations were at one time three or four to the minute, skin cold and bathed with perspiration, face cyanosed, etc. Recovery took place without subsequent accident.

DR. JOEL FOSTER related a case in which a patient of his, a young man, bought twenty-five grains of sulphate of morphine, and, thinking to have a pleasant time, made a pint of exceedingly strong decoction of coffee, put all the morphine into it, and drank the whole. He went to bed expecting soon to go to sleep, but instead of that he did not sleep at all, but became very crazy. His face was flushed, and he did not be-

come cyanosed. In about twenty-four hours he was entirely beyond the influence of the drug, and felt as well as ordinary, except the debility, and is now living. The doctor was of the opinion that the story of the boy was true with regard to the amount taken, and also that it was a good article, for it came from a reliable drug-store. The case occurred about twenty years ago.

DR. ROGERS wished some gentleman to explain the cause of the mental perversion alluded to by Dr. Baylis in his case.

DR. SMITH replied that he thought it to be due to the atropine; that it was the result of atropine poisoning rather than the opium poisoning.

DR. SELL referred to some cases in which very small doses of opium have produced fatal results. These cases are reported in the *Physician and Pharmaceutist*. He opposed the use of opium in any form in the treatment of diseases of children.

DR. PEASLEE referred to a case where a young girl had taken half a bottle of morphine; probably thirty grains, with suicidal intentions. This patient was marched to and fro, flagellated, and had about one pint of strong coffee, and in about six hours, she began to manifest some consciousness. Her breathing was stertorous, and withal it was a desperate case. It occurred a good many years ago, and before the battery and atropine had come into general use. With regard to the use of opium in the treatment of children, he always opposed the use of *laudanum or morphine*, before the child was, perhaps, one or two years old; but he did not exactly agree with Dr. Sell, that opium should never be administered.

DR. BLAKE remarked that he had already reported a case of aconite poisoning in which a congested condition of the kidney was found, and he was of the opinion that it is not unreasonable to expect a similar condition of the kidneys in opium poisoning. It has been said of late that it is well to examine the urine in every case. In a case of opium poisoning which he had reported, where recovery took place, all symptoms of narcosis seemed to pass away, and then a state of coma came on which was difficult for him to understand. It seemed to be prolonged to beyond the effect of the poison, and he now believes it was from the effect of renal congestion. (It is a fact of which, perhaps, every practitioner is cognizant, that a certain number of patients, while coming under the influence of opium, for instance in the treatment of peritonitis, suffer from suppression of urine more or less marked.)

DR. HUBBARD referred to a case of opium poisoning in which the alarming symptoms manifested themselves twelve hours after taking ℞xx. of Magendie's solution of morphine hypodermically at two doses, half an hour apart.

The respirations were reduced to eight to the minute, deglutition was impossible, the pupils were contracted, and the sphincters relaxed, etc. As a result of consultation, $\frac{1}{2}$ of a grain of sulphate of atropia was administered hypodermically, and in fifteen minutes the pupils were widely dilated. Respiration soon began to increase in frequency, and in about an hour he left the patient doing very well, but never expected to see him alive, supposing that the atropine would kill him. The next day, however, at 11 o'clock, he found him comparatively comfortable. He died four or five days after of pleuro-pneumonia, but the doctor was of the opinion that the influence of the opium had entirely passed away, and could not be reckoned as an immediate factor in producing the death of the patient.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 18, 1875, to April 24, 1875.

McCORMICK, CHAS., Surgeon.—Granted leave of absence for four months, with permission to go beyond sea. S. O. 69, A. G. O., April 19, 1875.

HAMMOND, J. F., Surgeon.—Granted leave of absence for one month on surgeon's certificate of disability. S. O. 67, A. G. O., April 15, 1875.

MOORE, JNO., Surgeon.—Assigned to duty as Medical Director of the Department. G. O. 5, Department of Texas, April 13, 1875.

JAQUETT, G. P., Assistant Surgeon.—Assigned to temporary duty with Geologist's escort to the Black Hills. S. O. 44, Department of the Platte, April 13, 1875.

KINSMAN, J. H., Assistant Surgeon.—Leave of absence extended one month. S. O. 62, Department of Dakota, April 15, 1875.

WHITE, R. H., Assistant Surgeon.—Leave of absence extended six months, with permission to go beyond sea. S. O. 67, c. s., A. G. O.

ELBREY, F. W., Assistant Surgeon.—Assigned to duty at Lebanon, Ky. S. O. 52, Department of the South, April 21, 1875.

HOFF, J. V. R., Assistant Surgeon.—Assigned to temporary duty at Fort Sanders, during temporary absence of Dr. Jaquett. S. O. 44, c. s., Department of the Platte.

SKINNER, J. O., Assistant Surgeon.—Leave of absence extended one month. S. O. 69, A. G. O., April 19, 1875.

Medical Items and News.

CENTENARIANS.—*The New York Times* of the 18th inst. publishes an interesting table, compiled by Dr. John T. Nagle, Deputy Registrar of Records of the Health Department of this city, which gives the names and conditions of ninety-eight centenarians, whose deaths have been reported to the Board of Health since 1864, and which we reproduce, since the question has lately been raised whether authenticated cases exist of persons who have attained the age of one hundred years.

Mary Nixon, born in Ireland in 1765, died in this city, Aug. 26, 1873. She was attended in her last illness by Dr. John H. Wilson, who stated that she died of softening of the brain, nervous exhaustion, and old age, her memory and eyesight having completely failed previous to her death.

Patrick White, born in Ireland in 1771, emigrated to New York City in 1853, where he died, aged 102 years, July 25, 1873. Dr. J. R. MacGregor attended him in his last illness. Mr. White was married between the ages of forty-five and fifty. His occupation in Ireland was that of a farmer, and his diet while there consisted principally, according to his own statement, of potatoes and milk, with an addition sometimes of fish and eggs. He did not eat meat more than once or twice a week, and oftentimes not more than once a month. He drank liquor moderately, and after his arrival in this country performed no hard work.

Mary McGrath	March 14	1873	100		Widow	Ireland	23 years	White		Senile asthenia.
Mary Monaghan	March 22	1873	102		Widow	Ireland	25 years	White		Senile asthenia.
Mary Tobin	April 1	1873	100		Married	Ireland	53 years	White	Housework	Dementia.
Thomas Craig	April 26	1873	102		Married	Ireland	40 years	White		Senile asthenia.
Alexander Scott	Nov. 23	1873	100		Widow	Delaware	28 years	Colored		Senile asthenia.
Mary Nixon	Aug. 26	1873	108		Widow	Ireland	25 years	White	Domestic	Softening of brain.
Patrick White	July 25	1873	102		Widowed	Ireland	19 years	White	Farmer	Senile asthenia.
James Reilly	Jan. 28	1874	106			Ireland	32 years	White		Senile asthenia.
William Louis	Feb. 4	1874	106	2 10	Married	France	26 years	White	Merchant	Pneumonia.
Margaret Cloonan, or Cronan	March 17	1874	103		Widow	Ireland	25 years	White		Chronic bronchitis.
Catharine Callahan	April 6	1874	104		Widow	Ireland	45 years	White		Pneumonia.
Mary Bliss	July 30	1874	108		Widow		9 years	White		Senile asthenia.
Molly Sheridan	Sept. 6	1874	100		Widow	Ireland	46 years	White		Diarrhoea.
Ellen Lyons	Aug. 31	1874	112		Widow	Ireland	42 years	White		Senile asthenia.
Jacob Kissam	Oct. 17	1874	123		Widowed	New York		Colored	Laborer	Paralysis.

Thomas Craig, born in the County of Leitrim, Ireland, in 1771, came to the United States twenty-nine years previous to his death. His occupation in Ireland was that of a wheelwright and carpenter, and in this country he became a porter. He was twice married, but had no children. About a year previous to his death he was injured by falling from a car, and was more or less childish from that time until he expired, at over 100 years of age. His wife is still alive, and is aged eighty-three years.

Hannah Ruland, *née* Wilson, born Aug. 29, 1774, at Oyster Bay, Long Island, of Scotch parents, died in this city, October 26, 1873. She was married at the age of sixteen years, and was the mother of ten children. Her mother was married at the age of thirteen years and six months, and gave birth to sixteen children, eight girls and eight boys, all of them distinguished for remarkable longevity and robust constitutions. The youngest child was over fifty years old when the first death occurred in the family, and one of the male children nearly reached his one hundredth year. Mrs. Ruland performed her household duties with punctuality, and her longevity was attributed in a great degree to certain habits to which she rigidly adhered during lifetime—one of them being that of retiring to bed at sunset and rising with the sun. She always insisted on having eight or nine hours' sleep, and at regular hours; partook of plain and substantial food, with tea and coffee. She never wore corsets, or indulged in alcoholic liquors, and was robust and muscular. Her height was 5 feet 4½ inches.

Christopher Rush, colored, born in Craven County, North Carolina, in 1777, died in this city of senile asthenia July 16, 1873. He was brought to this city a slave in 1798, and gained his freedom about the year 1812. He joined the African M. E. Church in 1803, and was licensed to preach in 1815, ordained in 1822, and elected Bishop of the church in 1828. He lost his eyesight in 1859, and in 1868 became subject to fits at intervals of from one week to two months, which greatly impaired his memory, and continued until his death. Frugality in his earlier years enabled him to save enough money to make him independent, so that he lived comfortably in his old age. He was a hearty eater, very fond of coffee, of which he drank a great deal, and was an inveterate tobacco smoker. He was naturally robust and healthy, and drank no liquor stronger than cider.

Alexander Scott, colored, born in Delaware in 1775, died in this city of senile asthenia at the age of 100 years, at the Colored Home, to which he had been admitted in October, 1871. His father's death was caused by the rupture of a blood-vessel, and his mother died of old age.

John McGibney, born in Ireland in 1776, died in this city, Jan. 11, 1873, of pleurisy. He came to this country in 1866, and was employed as a laborer, working occasionally until a few weeks before his death. He was of temperate habits, and during his lifetime his diet consisted of the humblest fare. He was muscular and of medium stature, and enjoyed excellent health until his last illness.

THE MAXIMUM DEATH-RATE DURING THE DAY.—In a recent number of the *Philadelphia Medical Times*, Dr. Behrens presents some statistics relative to the proportion of deaths at different hours of the day. These statistics suggest a field of investigation that hitherto has been but little explored, but which is none the less an important one. Were it known that dissolutions were more liable to take place at certain of these periods

than at others, the inference would be plain that when our patients approach the extremity of disease our efforts should be redoubled to carry them over the critical periods.

Dr. Behrens has compiled the subjoined table from over a thousand mortal cases which occurred in the Philadelphia Hospital in the course of fifteen months. Therein is shown the proportion of deaths during each period of one, two, three, four, six and twelve hours in the twenty-four.

HOUR.	I	II	III	IV	V	VI	TOTAL.
	In each hour.	In each 2 hours.	In each 3 hours.	In each 4 hours.	In each 6 hours.	In each 12 hours.	
Midnight							
1 A.M.	49						
2 "	48	88					
3 "	29		127				
4 "	39	76		164			
5 "	59						
6 "	59	109	146		273		
7 "	82						
8 "	65	146		255			
9 "	52		198				
10 "	59	111					
11 "	28						
Noon	46	84	143	195	341	614	
1 P.M.	45						
2 "	37	82					
3 "	39		121				
4 "	55	92		174			
5 "	32						
6 "	48	80	133		254		
7 "	47						
8 "	35	82		162			
9 "	34		116				
10 "	36	70					
11 "	28						
12 "	25	53	89	123	205	459	1073

We see that in these 1073 cases the maximum death-rate was 82, and occurred between the hours of 6 and 7 in the morning; the minimum was 25, and was between 11 and 12 P.M. We conclude from this table that mortality increases suddenly at midnight and gradually rises until about nine in the morning, when it again declines more or less regularly until it reaches its minimum, a little before midnight.

The full explanation of these variations awaits further inquiry. Dr. Behrens, however, mentions two causes which he thinks are especially important in this connection, namely: "nursing and the solar influence." The influence of the sun upon vital processes, although the precise nature of their relations to each other is yet obscure, is an undisputed fact, and the coincidence that the period of greatest mortality corresponds with the time at which the solar influence has been longest withdrawn, is, to say the least, significant. But it is remarked that the decrease in the death-rate continues for some time after sunset, and this would appear not to accord with the proposed theory. This, however, is explained by reference to the fact that "the effects of the sun do not disappear with it," and by supposing that the absence of the sun's rays is compensated in some measure by the extra attention paid to the patient's comfort as night approaches, and to the soothing influences of quiet and security from disturbance.

Again, in the early morning hours, after a night of watching, the vigilance of the attendants is very apt to be relaxed. The measures that have been administered at regular intervals during the night are more liable as dawn approaches and the watchers become wearied and sleepy, to be neglected, and, it may be, the spark of life is extinguished, when, possibly, a little nourish-

ment or a few drops of stimulus might have averted the impending danger.—*Phil. Med. Times*, April 3, 1875.

GASTROTOMY FOR STRICTURE OF THE OESOPHAGUS—According to the *Lancet* of March 27th, there was at that time in St. Thomas's Hospital a man upon whom Mr. Sydney Jones had performed the operation of gastro-tomy. Three weeks had then elapsed and the fistulous opening was complete. All the sutures had been removed and the patient was sitting up. His pulse was 80, temperature normal, and he showed no bad symptoms so far as the gastro-tomy was concerned. Fuller details of the case are promised.

DR. ALFRED N. BEACH, Member of Assembly from New York city, has introduced in Assembly an act to amend chapter four hundred and thirty-six of the laws of 1874, entitled "An Act to Regulate the Practice of Medicine and Surgery in the State of New York," passed May 11, 1874. Dr. Beach's amendment does not differ very markedly from the one published by us a short time since, being somewhat shorter but having the same general features.

SUCCESSFUL CÆSAREAN SECTION IN A CASE OF UTERINE FIBROIDS.—Dr. Cazin has had occasion to practise the Cæsarean operation in a case of uterine fibroids, and has had the good fortune to save the mother and child. He operated on a woman, aged thirty-nine, in whom, towards the sixth month of pregnancy, fibroid tumors were recognized in the posterior and inferior wall of the uterus. Labor set in the seventh month; after four days of pains the membranes ruptured, and a hand escaped, the child being still alive; but as it could not be extracted, either by forceps or by version, recourse was had to the Cæsarean operation. The most minute precautions were taken; there were hemorrhage and syncope, inertia of the uterus, distention of the belly to such a degree that it became necessary to puncture the bowel to give exit to the gas; there was vesical paralysis, and an abscess formed between the uterus and the abdominal wall. In spite of these complications the patient got well, and the child, baptized Cesar, thrived. It has since been ascertained that the fibroids are diminishing in size.—*Gaz. Méd. de Paris*.

NEW YORK STATE BOARD OF MEDICAL EXAMINERS.—The Eclectic Board of Medical Examiners, appointed by the Regents of the University, is as follows:—Dr. J. Edwin Danielson, of Little Falls; Dr. Alexander Wilder, of New York; Dr. Robert Hamilton, of Saratoga Springs; Dr. Hermann Beokowitz, of Brooklyn; Dr. D. W. White, of Ithaca; Dr. Robert S. Newton, of New York, and Dr. Orin Davis, of Attica.

CENTENNIAL MEDICAL COMMISSION, PHILADELPHIA.—The Committee of fifteen of the Philadelphia County Medical Society have selected the following officers to take charge of the medical representation at the Centennial Celebration in 1876:—*President*, Samuel D. Gross, M.D., LL.D., D.C.L., Oxon.; *Vice-Presidents*, W. S. W. Ruschenberger, M.D., U. S. N., Alfred Stillé, M.D.; *Secretary*, William B. Atkinson, M.D.; *American Corresponding Secretary*, Daniel G. Brinton, M.D.; *Foreign Corresponding Secretary*, Richard J. Dunglison, M.D.; *Treasurer*, Caspar Wister, M.D.

Executive Committee.—Washington L. Atlee, M.D.; D. Hayes Agnew, M.D.; Robert Burns, M.D.; David Burpee, M.D.; Isaac L. Eshleman, M.D.; Albert Fricke, M.D.; Nathan L. Hatfield, M.D.; H. Lenox Hodge, M.D.; Wm. H. Pancoast, M.D.; Robert E. Rogers, M.D.; J. G. Steller, M.D.; Laurence Turnbull, M.D.; Edward Wallace, M.D.

At the session of the Commission held April 19, the following committees were appointed:—*On Hall*—Drs. W. H. Ford, A. Fricke, R. J. Dunglison, Levi Cutis, Edward Wallace. *On Correspondence*—Drs. W. B. Atkinson, D. G. Brinton, R. J. Dunglison. *On Finance*—Drs. Caspar Wister, J. G. Steller, D. Burpee. *On Museum*—Drs. Joseph Leidy, J. Solis Cohen, T. G. Morton, Robert E. Rogers, Charles K. Mills. *On Arrangements, etc.*—Drs. Washington L. Atlee, Robert Burns, Wm. Pepper, W. H. Pancoast, L. Turnbull, J. S. Eshleman, Emil Fischer. *On Publication*—Dr. F. G. Smith, the three Secretaries and the Treasurer. *On Entertainment*—To consist of the whole Executive Committee. *On Addresses and Business of Sections*—Drs. J. H. Packard, D. Hayes Agnew, H. Lenox Hodge, N. L. Hatfield, A. C. Bourneville. It was agreed that all American delegates to the International Medical Congress shall pay five dollars on registering, to aid in defraying the expenses of publication. That a dinner shall be arranged for, and each delegate be charged five dollars for a dinner ticket. Foreign gentlemen in each case to be regarded as guests. The following arrangements were made for addresses: *On Medicine and Medical Progress in the United States*—Prof. Austin Flint, Sr., of New York. *On Surgery*—Prof. Paul F. Eve, of Nashville, Tenn. *On Obstetrics*—Prof. Theophilus Parvin, of Indianapolis, Ind. *On Materia Medica and Therapeutics*—Prof. Alfred Stillé, of Philadelphia. *On Medical Jurisprudence and Toxicology*—Prof. Stanford Chaille, of New Orleans, La. *On Hygiene and Social Science*—Dr. Henry I. Bowditch, of Boston, Mass. *On Medical Biography*—Dr. Joseph M. Toner, of Washington, D. C. *On Medical Education and Medical Institutions*—Prof. N. S. Davis, of Chicago, Ill. *On Medical Literature*—Prof. L. P. Yandell, Sr., of Louisville, Ky. *On Mental Hygiene and Medicine*—Dr. John P. Gray, of Utica, N. Y. *On Physiology*—Prof. Leon S. Joynes, of Richmond, Va. *On Medical Chemistry and Pharmacy*—Dr. Wormley, of Cincinnati, Ohio.

REDUCED FARE TO LOUISVILLE, KY.—Delegates who propose to attend the next meeting of the American Medical Association, to be held in Louisville, are offered reduced rates by the Erie, and Atlantic and Great Western route, provided any number of tickets exceeding fifteen can be purchased at one time. An excursion ticket over this road can be procured at a great reduction of the usual rate. Those who do not prefer to take advantage of a round trip ticket can have a proportionate reduction for a single trip. This road, as far as we are at present informed, is the only one which is inclined to be liberal to the delegates from New York attending the Louisville meeting. In order to arrive at Louisville in time on Tuesday morning, it will be necessary to make the start not later than Sunday evening at 7 o'clock. Tickets can be purchased and sleeping cars procured on application at the Erie R. R. office, 957 Broadway, cor. 23d street.

WEEKLY BULLETIN OF MEETINGS OF SOCIETIES.

Monday, May 3.—Medico-Chirurgical Soc.; Morrisania Med. Soc.; N. Y. Neurological Society; Path. Soc. of Brooklyn.

Tuesday, May 4.—N. Y. Obstetrical Society; East River Medical Assoc.; N. Y. Dermatological Soc.; District Medical Society for the County of Hudson, Jersey City. Facial Paralysis, by Dr. Lampion. American Medical Association at Louisville, Ky.

Thursday, May 6.—N. Y. Academy of Medicine.

Friday, May 7.—Medical Library and Journal Assoc.

Original Communications.

ON SOME OF THE ELEMENTS OF DIAGNOSIS IN THE DIFFERENT STAGES OF DISEASES OF THE HIP-JOINT.

By C. FAYETTE TAYLOR, M.D.

(READ BEFORE THE NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION, APRIL 16, 1875.)

THE importance of an early and correct diagnosis of disease in the hip-joint must be apparent to all. But diagnosis implies much more than a recognition of existing disease. It embraces, or should embrace, such a careful analysis of the existing facts, as to resolve the condition into distinct and well-defined elements, which are separately comprehended, and which, being correctly interpreted, are the indications to which our treatment ought directly to respond.

Now, such a diagnosis is not to be evolved from one's "inner consciousness," nor is it to be arrived at through indefinite generalization. Of course there are stages and degrees of this disease which advertise it to the dullest comprehension and to the most careless observer. But to wait for a disease of such gravity to obtrude itself on one's notice is not the part of that scientific observation which seeks to anticipate disaster by searching out the evidences which precede and portend it. If these evidences are sometimes obscure and inferential, there is all the more reason for diligence and painstaking, and all the more honor for successfully anticipating the graver conditions which are sure to come.

An experience which has not been small, and an observation which has been as careful as I could make it, have brought me to these two general conclusions, viz.: 1st. The symptoms generally relied upon as diagnostic of disease of the hip-joint are worthless for all practical purposes of either anticipating the graver stages of the disease, or of affording indications for treatment. They pertain, for the most part, to the fully developed disease, and are therefore observed too late for the higher purposes of diagnosis; and 2d, the symptoms of impending danger to this joint exist, in the majority of cases, long before the time of actual danger has arrived, and it is possible—I might almost say it is *always* possible—to anticipate, by prompt and effective treatment, and to prevent, by cutting short the disease, the development of those symptoms which, at a later and less curable stage, are often relied on for evidence of the disease itself.

To be precise, let me say that I have no confidence in the fact of pain as a symptom from or through which we may justly draw conclusions of any definite value whatever, at any period of disease pertaining to the hip-joint. To those whose observation has been limited to painful stages of this disease, and who have witnessed the terrible sufferings of these patients, the above remark may excite surprise. But please remember that I am not denying the painfulness of this disease—there is none more painful; but I do deny that pain has any important diagnostic value. It is a symptom which varies more than any other in different individuals, and in different stages of the disease in the same individual. It does not always exist, and, when it does exist, it indicates nothing which is not better found out by more constant and more uniform indications. Therefore, as a necessary conclusion, I feel obliged to eliminate to a very large extent—not

wholly, but to a very large extent—the patient's own impressions in regard to himself, and to make my deductions from evidences outside of his consciousness. I believe in the traumatic origin of disease of the hip-joint as the ordinary cause. I do not deny that there are cases of its idiopathic development.

Indeed, I feel confident that I have seen such cases. But it is not necessary, for our present purposes, to discuss the etiology of this disease further than to say that statistics demonstrate the traumatic causation in the large majority of cases, and we will confine our theme to this majority. Now, there are accidents of sufficient severity—blows, falls, slips, strains—to cause immediate pain, or painfulness following after a certain interval. But the mere fact of painfulness is nothing unless it be accompanied by other and more important signs. We may have muscular or hysterical hyperæsthesia (I use the word for want of a better), or painfulness quite as severe, with the patient quite as reluctant to submit to handling, developed by an accident when there is no disease of the joint whatever. But the most important fact, in this connection, is that we may have a dangerous amount of disease of the hip in any stage, and especially in the early stage, without any painfulness whatever. To wait for painfulness to be developed in a case of suspected hip-joint disease, where this symptom is absent, is simply to wait for that combination of circumstances which develops pain. This combination of circumstances may occur at any stage in the progress of the disease.

In some rare instances it may be practically absent during the entire course, from the first inception to ankylosis. But what I more particularly insist on is, that the fact of or the amount of painfulness is a very imperfect indication of the presence of or the extent of disease in this joint. To me, in my experience, the absence of pain, or, which is not always the same thing, its denial by the patient, indicates a graver condition than the presence of acute suffering.

To point my remarks by an illustration, let me relate the history of the following case:

T. C., of Chicago, Ill., aged five years, applied June 17th, 1872. The records are long and not all of them pertinent to our inquiry, and I only condense so much as relate to the subject under consideration. The patient was found with the right hip flexed at an angle of about forty-five degrees, but walking briskly, limping in consequence of the shortening, but denying all pain.

I should here remark that by the absence of pain I always mean *conscious* pain—the pain which the patient, on being questioned, will localize and admit. But I do not include those involuntary and unconscious evidences of general physical distress which almost always exist, and, taken together, furnish some of our best diagnostic signs.

In this case, though the child ran about, apparently as freely as any child, and denied all painfulness either in walking or on being moderately handled, yet the mother admitted that he would occasionally cry out in his sleep. She had called at my office one year before to put the case in my hands for treatment for the existing deformity, but finding that I was absent and not likely to return soon, she had waited till she had heard that I was at home again. During all of this time, according to her story, the symptoms had remained unchanged; there had been no complaint in running about, no limping from conscious soreness in the joint or anything which, to her observation, required prompt measures of interference.

She was very much surprised when I told her that the child was in a very dangerous situation, and I re-

fused to have anything to do with the case except with the distinct understanding that, so far as suffering was concerned, the child would certainly be a great deal worse. Without treatment it was only a question of time, for death of the bone, with its attending dangers, would occur; and with treatment, increased physical suffering was inevitable.

Now, what were my reasons for such an opinion?—Simply these:

There is not a very high sensibility in the tissues pertaining to the hip-joint, unless developed by an acute inflammation, or by the swelling of the coverings of the articulations beyond the capacity of the narrow space to contain them causing pressure, or by the rubbing together of diseased surfaces.

Now, we may have an inflammation of the articular surfaces developed gradually by successive slight injuries—and indeed this is the way that the greater number are developed; the inflammatory process may be extending first to the cartilaginous investment, and then to the bone itself, but not at so rapid a rate as to reach the stage of conscious pain; or the swelling may not be sufficient to fill the space, and cause painful pressure. In such a state of things as I have described, the source of pain would be motion—the friction of inflamed surfaces. But if motion is estopped by uniform muscular action, there will be no pain, while the conditions above mentioned are maintained. But if the swelling and inflammation increase *beyond a certain point* the pain will be developed. Or, if the muscular contraction is not sufficient to prevent friction, or, if having been sufficient, it diminishes in consequence of rest, and a receding of the inflammation in the joint, there will be conscious pain. In other words, it is possible to have pain as a direct consequence of a partial improvement in the patient.

Now it so happens that in cases characterized by a diminished amount or entire absence of pain, during a certain period, there is invariably a uniform degree of muscular contraction sufficient for entire arrest of motion during locomotion, and on examination also, except with very delicate manipulation, or with a hurtful amount of violence. But an amount of muscular action sufficient to arrest motion in the joint (with the present effect of preventing the painfulness) is a very serious factor in the case.

The first effect of such strong and long-continued pressure is generally to deaden the sensibility, if there is only a moderate amount of inflammation. But such long-continued pressure must prove destructive to the parts pressed upon. Congestion, and finally the death of the bone, take place, with extensive suppuration and all the usual phenomena attending such a catastrophe. Moreover, a uniform muscular contraction, sufficient in degree to permanently arrest motion, is very often mistaken for ankylosis, and also is frequently confounded with the muscular rigidity resulting from long-continued disuse. I shall refer to these last-named conditions before the completion of this essay. It is sufficient for my present purpose to say that that form of muscular rigidity which results from the atrophy of non-use does not occur in the first years of disease of the hip-joint, nor, in fact, do the muscles ever lose entirely their irritability, contractility, and elasticity during any period of inflammatory action.

Fibrous ankylosis, except in rare instances, occurs very late indeed—generally several years after the subsidence of all diseased action; and osseous ankylosis is of such rare occurrence that it is not easy to meet with a specimen in pathological museums.

But to return to our case. It was a correct inference that there could not have been continued pressure in

the joint to the degree of arresting motion without damage. I could easily detect in his countenance and general appearance evidences of vital depression which a progressive disease imparts. I considered it a worse case than if there had been less muscular action and more painfulness during the preceding months.

I need not narrate the case further than to say, that on overcoming the muscular contraction through effectual counter-extension, painfulness on motion was developed which lasted for considerable time, but which finally subsided as time was given for the inflammation to subside, and the case was cured, leaving good motion at the joint.* I should say further that at one time we removed by aspiration a small amount of pus from close proximity to the joint. After diminishing the force of the muscular action, but before they were entirely overcome, and before the inflammation had time to subside, there was a period of spasmodic and variable muscular contractions, identical with what we see in other cases, which have not had periods of the uniform muscular action to which I am calling your attention. It is the unequal muscular contraction which is one of the greatest sources of painfulness, because we have variable pressure in the joint, accompanied with motion as the muscular action varies.

The kind of muscular action, whether uniform or spasmodic, varies immensely with difference of temperament, with the amount of, and also with the different stages of, the disease.

A difference must be observed between that which is purely of a reflex nature, as the direct consequence of local irritation, and that which is the result of an instinct—a physical instinct in contradistinction from volition, though the latter may also participate. Though all these different sources of muscular irritation often act together as factors in the production of a given result, they are nevertheless capable of practical analysis in any given case. As a matter of clinical experience, I find that where a case comes to me with a history of prolonged lameness, with intervals of apparent exemption from such lameness; the subject, as a general rule, having been treated for "rheumatism," or the mother told that it was a "habit" which the child would "outgrow" in time, but denying pain in walking; the child running about and, perhaps, going to school like other children, but with more or less uneasiness and occasionally crying out at night in sleep, we invariably find a case, on examination, of uniform tonic, muscular contraction, and an immovable joint. Very frequently, however, we do not see the child till after the prolonged muscular compression in the joint, assisted, perhaps, by some slight injury, has developed more active symptoms. Now, during all this period of occasional so-called "rheumatism" or "growing pains," but exemption from those more acute symptoms considered characteristic of disease of the hip—and which do characterize certain periods of that disease—we have had simply the operation of the muscular instinct to prevent motion, *because* there was disease in the joint. If this muscular effort to arrest motion was successful in the temperaments, and under the circumstances calling it forth, it does not follow that it will produce the same result in another temperament or under other circumstances. Hence, while in certain cases—notably those of slow accession of the disease—the first symptom

* Since this paper was prepared I have learned, by a letter from the patient's mother, that at her first visit to New York, during my absence, and a year before the commencement of his treatment, he was taken to a surgeon here who examined him under ether, and said there was no disease of the joint.

which attracts attention is a slight shortening of the leg, and consequent limping; the flexion *not* preceded by eversion and abduction, and apparent lengthening, together with an absence of pain in locomotion, and rigid and uniform muscular contraction rendering the joint immovable, we have other cases which have been incorrectly taken for types and stages, with limping from pain, whom we find intolerant of, and fearing motion, and on examination we find less muscular action and more motion; those are the cases which evert the foot, with abduction of the leg. As a rule, I find the class of cases first above mentioned—those temporarily without pain, or with so-called "rheumatic" pains—to be the more serious of the two. But it should be remembered and accepted as a cardinal principle in the diagnosis of any disease of the hip-joint, that the muscular instinct is much more quick, and precedes by a relatively long period, the mental consciousness. A very slight injury to the joint, the merest trifle of inflammation resulting from such injury, will cause an immediate response of muscular action which can be appreciated by the examiner for the purposes of diagnosis, while the disease must have advanced to a considerable degree before the patient becomes mentally conscious of anything wrong. Of course, I reject etherization as being utterly valueless as a means to assist in diagnosis, and am simply amazed that it is ever used for that purpose. To relax the muscles is to destroy the most delicate evidence of suspected disease. A case or two in illustration of the foregoing views may help to fix them more firmly in the mind.

D. W., aged seven years, in fair health and of healthy parentage, was brought to me on the 18th of June, 1874. A few hours before she had complained of an ill-defined pain in the right leg on rising in the morning, and limped observedly for the first time. Having an older child who had had disease of the hip-joint, the parents were alarmed and brought the child at once for examination, though the pain was so slight that no notice would ordinarily have been taken of it. On close questioning they remembered that a similar complaint—a mere passing allusion of an ache in the leg—had been made about two weeks before.

On examination, I found all the muscles involved in the movements of that thigh in a state of excessive tonic action. Unless the pelvis was firmly held it would move as the leg was moved, but with slow and carefully applied force, the pelvis being held, complete motion could be made at the hip-joint. But there was no consciousness of pain or shrinking from it on such motion, though there was evident muscular irritability. As the child's parents could not recall another instance of previous lameness, we deferred treatment, further than to order the recumbent position till the 20th, when, there being no change, we applied extension and carried it to the complete relaxation of the muscles. This required about six weeks to accomplish, when there was no apparent difference in the two joints as indicated by any difference in the condition or action of the muscles.

But we are not to assume that with the absence or subsidence of pain there is no disease. Neither are we to assume that with forcible relaxation of the muscles and the subsidence of all symptoms of active disease in the joint, the case is already cured. It requires time, and sometimes a good deal of time, to complete the reparative process.

It is evident that the protection of the joint must continue till the structures involved in the inflammation are fully restored to their former integrity. In this case the relief was too prompt and thorough, and

the parents' anxiety was so entirely removed, that, after a few months, they ceased their regular visits, when, returning after a longer interval than usual, I found that stiffening of the muscles had returned. On searching for the cause, I found that, with the growth of the child, which was very rapid at that time, and the natural yielding of the instrument from wear, it had become too short, or rather, the leg had become too long, and instead of being supported by the instrument it was simply running through it with the heel resting on the bottom of the shoe. Thus the hip was receiving the weight of the body once more.

The instrument was lengthened, and in a few weeks all extra muscular tonicity had disappeared. The same thing has happened in many other cases under similar circumstances, and several times through carelessness in the same case. I relate this case, which is simple enough in itself, because the watchfulness of the parents in the first instance, and their too great confidence in the second place, gave me an opportunity of observing certain phenomena at an unusually early stage, which I am satisfied take place in a very large number of cases, though we do not always see them till after what was at first mere hypertonicity of the muscles is gradually converted into uniform muscular spasm with complete and constant arrest of motion, and this condition, either by the natural progress of the disease, accelerated by the constant, injurious effects of the increased pressure caused by the muscular action; or, it may be, aggravated by an injury—a misstep, a slip, or, perhaps, a fall—but often so slight that no symptoms would follow in a healthy joint, passes rapidly after a certain stage into that stage which is accompanied by the exerting suffering so often witnessed.

It is my opinion that this is substantially the history of most cases of disease of the hip-joint; that there are very few cases where the disease is developed as the result of a single injury, though the injury immediately preceding the accession of the painful stage generally gets the credit of causing the disease. It follows as a logical inference, from the preceding,—and this conclusion is borne out by the facts which constantly come to notice,—that if there is danger in waiting for the development of the more distressing symptoms in case of suspected disease of the hip-joint, before admitting its presence, there is still more danger in abandoning any treatment which has been successful in relieving the pain, or in being satisfied with such treatment merely because it has been successful up to that point. Of course, any successful treatment must of necessity bring relief to the patient's sufferings. But such relief from pain may be more or less perfectly obtained by means which are quite incapable of effecting a radical cure of the disease. And here I think is the point where the inexperienced are liable to make the most frequent and disastrous mistakes both as regards modes of treatment, the length of time through which it should be carried, and the real condition of the patient. In many cases it seems to be assumed, that if a patient has been free from pain for a certain number of months, he is to be pronounced cured. There could be no greater mistake. The following cases are selected, with special reference to emphasizing the principles which I am insisting on. R. G., between three and four years old, was sent from Texas, with what was then called psoas abscess. The surgeons into whose hands he came at first considered it a disease of the hip-joint—rather by inference, as one of them informed me, than as having been made out from symptoms which they considered positive—and he was treated for such disease, at first by counter-

extension—various methods—the weight and pulley, and “Sayre’s” and Taylor’s splints, etc., and during several months of the time by the plaster-of-Paris bandage. Finally, after eighteen months or two years of treatment, as there was an entire absence of what they finally considered every indication of hip-joint disease, they came to the conclusion that the joint had not been diseased, but that there was a necrosis in its vicinity which involved and disturbed the muscular action, producing a certain amount of distortion similar to that which accompanies hip-joint disease. But this distortion could be readily overcome by the use of a little force, and the leg was easily brought down to its proper position without any pain or apparent inconvenience to the patient.

But on removing the opposing force, the thigh would assume its flexed and somewhat adducted position. At this juncture, viz., in January, 1872, Dr. Chrystie, in my absence, was called in consultation for the purpose of seeing if the existing deformity could not be removed by some mechanical means. On examining the child, he at once insisted that it was a case of hip-joint disease, then in active progress, and refused to treat it except for such active disease. A few months later, an abscess was discovered over the head of the femur, exploration revealed dead bone, and the joint was subsequently resected by Dr. Sayre, into whose hands the patient finally came. I have given this case, whose history is so exactly like many others, for the purpose of answering the questions which one of the surgeons attending him at the time Dr. Chrystie was called asked me not long ago. The first question was this. Said he: “We considered that there was an entire absence of any indication of disease of the joint. Now, what reason, in any symptom or condition of the patient, had Dr. Chrystie for coming to the opposite conclusion?”

My reply is, that Dr. Chrystie says he was satisfied that there was active disease going on in the joint the moment *he felt of the muscles*. It is the condition of the muscles which is the most constant and delicate diagnostic indication of hip-joint disease. “But,” continued my interlocutor, “the muscles were in a condition of contracture, technically so called. Now, how are we to distinguish between this case, where it is admitted there was disease, and another case in precisely the same condition which is actually cured?” My reply goes directly to the bottom of the whole matter. I deny that there are, or can be, two cases with the same condition of the muscles, one of which never has had the disease, or has been completely cured, and another who has any degree of joint disease. The mistakes in diagnosis arise from confounding as identical two conditions which are entirely different and wholly separable. A condition of so-called contracture is a permanent shortening of the muscles. It is characterized by increased rigidity and diminished contractility. The *diminished contractility* and diminished irritability are important to be remembered.

This condition of the muscles may result from various causes. It is especially likely to be found after long disease accompanied with the absence of all direct or reflex nervous excitation to action; as after fibrous or bony ankylosis and disuse of the joint.

But this condition of the muscles must not be confounded with nor mistaken for the constant, excessive, unrelaxing, tonic contraction, in greater or less degree, varied or not with spasm, but always present when there is any disease whatever in the joint. The latter may exist so slightly as not to prevent the extremest flexion and extension, or it may exist to such a degree

as to arrest all motion as completely as true ankylosis; but it can always be detected when we have a clear conception of its distinguishing characteristics. In the earliest stages of any injury to the joint, supposing such injury to be so slight as to produce the least possible inflammatory action, there may be a mere stiffening of the muscles, not enough perhaps to prevent motion, but always enough, when one is looking for it, for the educated touch to detect what I have named a *reluctance to relax*. It is quite independent of the patient’s volition, though it often requires careful management to prevent the voluntary efforts from mingling with and obscuring this condition, which is independent of the will. It is the first feeble involuntary intimation of an effort to arrest motion, which, further along, and after the disease has increased, becomes palpable enough to the most ordinary observation. It is chiefly in the earlier and later stages when mistakes of diagnosis are most likely to be made. In the beginning this symptom, being less pronounced, may be overlooked; and later, when it has increased to its greatest degree, it may be mistaken for contracture or permanent shortening; and it is also often mistaken for ankylosis when it is sufficient to arrest motion. In the stage of its higher activity there are two conditions by which muscular contraction—the increased, constant, tonic contraction here meant—may be distinguished from so-called contracture, or the muscular shortening for which it is so often mistaken. There is increase of irritability (independent of muscular power), accompanied with what may be called a relaxability, while muscles in a state of contracture or permanent shortening are characterized by want of irritability and by inelasticity. The former *relaxes* on the application of force. The latter stretches by its physical elasticity, or by the rupturing of inelastic fibrous tissue.

The one is a *physiological act*, the other is a *physical effect*. It is perfectly easy to distinguish between these two conditions. One is a physiological and the other is purely a physical condition. Now this physiological condition does, and necessarily must, exist during the continuance of any exciting cause, and it therefore becomes symptomatic of the cause which excites it. Not only that, any degree of increased muscular tonicity is not only symptomatic of the cause which excites it and clearly demonstrates the existence of such exciting cause, but it is of itself an important element in perpetuating and increasing the very condition which produces it. Anything more than the normal amount of tonic muscular action is a constant menace to the integrity of the joint on which its force is exerted. We may save ourselves the trouble of going behind the condition of the muscles. When the question relates to the hip-joint it is not necessary to demonstrate nicely the actual relative condition of the joint, for the indication for treatment exists when we have decided that the muscles are acting in the least degree beyond what is a usual and necessary functional tonicity. If we may infer, in certain instances, that the exciting cause is not probably within the joint, such muscular action, if not overcome, is likely to affect the joint sooner or later. In most cases it is only a question of time. Our first duty is to protect the joint, and then we may perhaps afford to wait, like Micawber, to see “what will turn up.”

I have already stated that it requires one (or more) favoring circumstances to develop painfulness; that this may happen at any stage of the disease when those conditions are present, and that the mere fact of a certain degree of painfulness, all other things being equal, is no true indication of the severity or extent of the

disease. Very much depends on temperament and the uniting of conditions favoring the production of painfulness, irrespective of the stage or of the amount of disease. The next case illustrates this aspect of the subject very well.

W. B. of Tennessee, thirteen years old, tall, well-nourished, but inheriting a nervous temperament, applied April 4, 1874, on recommendation of Dr. Agnew and Dr. Cook. Fifteen months before, he fell from a pony and hurt himself severely, but did not mention it for fear he would have to part with his pony. Soon after he began to complain of indefinite pains in the leg below the knee, which were called "growing pains," and often without complaining of pain he was seen to walk stiffly, or with a slight limp. Lately this had increased, and when he came to us his lameness was increasing rapidly. About the time his treatment began, severe paroxysms of pain set in with very great muscular contraction, so much so that the two well-padded perineal straps, which we use with our splint, could not be endured with the extension we felt necessary to give, and the weight and pulley were added to relieve, in part, the excessive pressure against the pelvis. I do not intend in this paper to discuss the mechanical treatment of hip-joint disease; but I will say here that I follow one indication, viz., to overcome completely the muscular action. I use the counter-extending force—not till the pain, if any exists, is relieved, but till the muscles relax.

In this case he had not only all the extension by the instrument which his perineum would bear without cutting, but besides the instrument the weight at the foot of his bed was increased till it reached fifty pounds. The equivalent of the instrument might have been a hundred pounds more. We had no means of estimating that. But it was carried till the muscles relaxed, and continued with this force—the instrument all he could bear and fifty pounds by weight and pulley additional—during six weeks, when the muscles were relaxed and he was let up, wearing the instrument only. He wore first the one and then the second instrument according to our method of procedure, and during the last two months he has been without anything. And now if any gentleman will examine him and can tell which was the affected leg, I should be very much obliged to him. Notwithstanding the violence of his symptoms, the disease must have been in its first stage or he could not have recovered so quickly and so completely. It should be borne in mind that I insist upon the fact of muscular action, rather than the degree of it.

Another case with a different history was a young lady, eighteen years old, of a healthy family, to whom I was called in Sept., 1872.

Some four or five years before—the time was a little indefinite in the remembrance of the family—she had slipped on the ice and had fallen in going to school. No immediate effects seemed to follow, but the family date a certain hitch or limp in her walk to about that time. There would be "rheumatic" pains from time to time, though not easily localized, but nothing to prevent her from attending to her ordinary duties, going to school, etc., till within a few months or perhaps a year before I saw her. Within that year she had several slips or slight accidents which aggravated her condition, and her attending physician, a few months before, had put her upon crutches, as a means of treatment, but not because she could not get about in tolerable comfort without such aid. Three weeks before I saw her, her crutches had slipped and she had fallen directly upon the affected hip. She was then put to bed, where she remained when I was sent for. She re-

ported having considerable pain during the first week following the accident, but after that she had been entirely comfortable. I found her exhibiting relatively few signs of physical distress. With care, the leg could be moved without moving the pelvis, and she complained of no hurt during such movements of the joint as I thought it necessary to make. At the time I saw her there was a virtual absence of all those symptoms of painfulness, rigid muscles, pelvis moving as the leg is moved, or pain in the knee, or muscular spasm; and except for the proper inference derived from the history of her case, the only indication which I had to guide me in making a diagnosis was the peculiar quality of muscular action about the suspected joint. The educated touch could not be deceived, and I gave the unhesitating opinion that the joint was seriously affected.

I give a synopsis of the history of this case more especially in order to introduce what follows. Several months afterwards, though she had no pain in the meantime, and the muscular contraction had been overcome, there were several symptoms which attracted my attention, the principal of which was a kind of stinging sensation at or near the acetabulum, and I made up my mind that there was pus in or about the joint. I consequently determined to aspirate it. On March 27, 1873, after taking the bearings as carefully as I could, I introduced the aspirating needle, intending to strike the joint on the inferior margin of the acetabulum. Whether I hit the point aimed at or not I cannot tell, for you must remember the thickness of the thigh of a young lady of ordinary size and in good flesh; but this I know that, on second trial, I drew out about a drachm of very thick pus.

The subsequent history of this case is interesting, especially in two points of view besides the want of ordinary intensity of diagnostic symptoms: First, as showing how extensive disease of the thigh may depend on previous disease of the hip-joint; and secondly, how the former may go on while the latter is recovering.

One aspiration followed another whenever there was any suspicion of pus, and several attempts were made without finding any, and so soon as fluctuation could be detected free incisions were made and every means used to evacuate the pus whenever and wherever it could be detected. Notwithstanding all efforts, pus was found as far down as just above the knee. Evidently portions of the fluid originating in the joint had percolated along the femur, stripping it of its periosteum and establishing points of independent disease at different distances from the original affection. In the meantime the joint itself has done remarkably well, and is now, to all appearance, entirely free from disease. It required, after the first few months, but the smallest amount of extension, there has been no pain, and the motion is perfect. In fact, I consider the joint itself to be well. But it should be and will be protected till the last evidence of necrosis of the femur, now fast improving, has disappeared.*

I may say, in this connection, that, as a rule, disease of the hip-joint in adults is accompanied with less severe symptoms than in children. Especially do we find a markedly diminished muscular action as compared with the same disease earlier in life. This may be the reason that I have found so many cases of disease of this joint in adult life which made slow and nearly painless progress through successive years, and arrived

* Several times during the course of the treatment of this case, in order to test the fact of origin of the disease still further, I tried the experiment of letting up the extension. In every instance, after a few days, there was observed a stiffening of the muscles, and once accompanied with soreness in the joint.

at the stage of ankylosis almost without the patient being aware that anything serious was the matter with him. Diminished vascularity, as age advances, may be reason for diminished intensity of the inflammation in adults when compared with children.

I hope I have been successful in satisfying those who have followed me so far, that it is never safe to dismiss a case as cured, no matter what may have been the method of treatment employed, merely because the pain has been relieved or that there is no hurt in locomotion.

I hope I have also made a sufficient impression to cause those who may place any reliance on my statements, to examine further and more carefully before concluding that want of mobility of the joint, without violent force, indicates ankylosis. A case on this point may be impressive.

In May, 1873, F. F. was brought to me for examination and opinion. She was then eight years old, bright and healthy, of excellent parentage, and had contracted hip-joint disease about five years before. The following items concerning the different stages of her case were taken from her father's statement: During the summer of 1868, fell on waxed floor in Paris; next January (1869) she was ill with scarlet fever, and complained of her knee and limped. Treatment begun January, 1870. Weight and pulley six months. Afterwards "Sayre's" splint was worn till October, 1870, when it was taken off and the patient pronounced cured. Summer of 1871 quite lame; electricity and *passive motion* (?) of leg twice a week. 1872, quite comfortable; limped a little. I saw her the first days of May, 1873. The leg was a good deal flexed, somewhat adducted, and the joint immovable from very strong, steady, uniform muscular action. I was told that the case had been pronounced cured by ankylosis. The occasional dull pains were said to be "rheumatic," for which White's rheumatic pills, Vichy water, and Russian baths, and various other things, were taken.

I gave my opinion in writing that the child had active inflammation in the joint, and that it was only a question of time before serious symptoms would be set up. The steady pressure of the head of the bone into the socket by the powerful, uniform, muscular action, was certainly increasing the mischief while they were dwelling in fancied security. My opinion was not acted on—it was probably scouted—the deformity must be overcome, and on the 6th of May, and again on the 15th, tenotomy was resorted to, accompanied with forcible extension, and the leg was brought down. Now, what was the condition left after tenotomy? Though temporarily diminishing the pressure in the joint, this procedure had made it impossible to prevent motion. A splint was worn for awhile, I believe, after getting up from the treatment connected with the operation, and finally removed. Now, if the thigh is extended on the pelvis, it only makes each step a harder blow in the unprotected joint than it would be if more flexed; and there is, in addition, the grinding motion with the compression of the still acting uncut muscles. The consequence in this case was, that the child began to grow worse immediately after beginning to walk about. I was again called ten months afterwards, viz., on March 18th, 1874, and found her lying with the leg flexed at right angles with the pelvis and abducted to the fullest extent possible (the adductors having been cut), and the little patient was in the most excruciating agony.

This stage had occurred much sooner than I had predicted, because the treatment had not been responsive to the indications then present. For I have never seen a case where the evidence of most powerful and

uniform muscular action indicated more clearly active disease in this joint than in the case above described.

My object in relating this is because it embraces so many and so clear points bearing on diagnosis. I do not wish it to be inferred that because tenotomy, according to my interpretation of symptoms, was not responsive to indications in the case above related that I condemn such a procedure in other cases or when it may be indicated. To cut tendons of muscles in active contraction is what I object to. The utter failure of tenotomy in this case was due to not distinguishing active, uniform, muscular contraction from ankylosis and the muscular contracture.

If the latter condition had existed it would have implied a cessation of diseased action in the joint, and the operation would have been probably successful. The failure was explained to me by the attending surgeon on the theory that there was ankylosis. That there could have been no union in the joint is proved by the fact that she now has excellent motion.

I will now give another case of tenotomy. A. S., from Canada, a girl nine years old, double hip-joint disease with several discharging abscesses on each side. This was a dispensary case. The girl was first taken (1869) with the disease in the right hip, and during the most painful stage the attending surgeon divided the tendons of all the muscles, apparently, which he could reach. I never saw such extensive tenotomy practised. To judge by the appearance left, and the almost utter want of use of the legs, I should infer that they had been nearly cut off. Immediate and complete relief followed the operation. The child went to sleep and slept through the night for the first time in many weeks. Later on (1870) the left hip became diseased, when tenotomy was again practised in the same manner, with the same immediate relief from suffering. This freedom from pain lasted from that day to the time of examination.

But this heroic treatment, notwithstanding its first effects, did not prevent the disease from progressing, and both hips became subsequently involved in extensive ulcerations, and abounded in abscesses; besides which, she had not sufficient muscular power left to move her legs properly. Ankylosis of both joints would have left a better result. I think that such extensive division of the tendons, without at the same time protecting the joint in locomotion (for only the weight and pulley were used for a while), the effect of which was to promote motion in a joint unprotected by efficient mechanical means and exposed to the influence of concussion and external pressure, afforded less chance of recovery than if the joint had remained immovable though subjected to the increased pressure of muscular contraction. The result in this case—the disease going on to the death of bone a long time after the operation had relieved the painfulness—seems to point that way.

My opinion is frequently sought by medical men in cases which seem to perplex them on account of the variableness of the symptoms; not seeming to know that variableness is almost a diagnostic characteristic of this disease. The child gets lame, and, after a time, gets apparently entirely over it. Then he is observed to limp, but on being interrogated may deny it, or for a time may have actual pain, especially at night; then he seems to be as well as ever. So it goes on perhaps for one, two, or three years possibly without any treatment, or it may be with short seasons of little dabs of treatment, first of one kind, then of another; but in every case, whatever is done is abandoned so soon as there is no more painfulness or the lameness is improved. Of course, if I were writing on *the treat-*

ment of hip-joint disease, I should say that treatment should have reference to certain conditions to be changed, and is not to be influenced by temporary alterations of symptoms. But this intermitting and changeable character of the symptoms, which seems to be the stumbling-block to the careless and inexperienced, is really an important diagnostic consideration. It points directly to disease of the joint, and represents the early history of the majority of cases. It is true, however, that careful examination at any period in the intervals of lameness, as well as at other times, would almost always reveal a tension of the muscles and impaired motion at the joint, which would clearly establish the character of the trouble. Our records are filled with cases like the following:

J. K. was injured by a fall in 1867; had no pain, but was very lame. Treated by family physician by recumbent position for eleven months; extension by weight and pulley attached to *ankles*; "cured," but still limping. Then counter-irritants to joint were applied. This condition continued two years, during which time the family traveled in Europe, and many surgeons were consulted in regard to lameness,* very few of whom, the father reports, suggested disease of the hips. I saw her in 1870, and at once saw the symptoms of progressive disease of the joint, and warned the father of approaching disaster unless timely aid was given. But he would not believe it. She had been pronounced either cured or without disease too many times. During all this time both parents and patient insisted that there had been no pain or soreness, and they, with their medical adviser, had rejected the idea of disease.

But the leg was somewhat flexed, which caused a halting walk, and it was for this lameness that we were applied to. However, as time passed, painfulness at times began to be manifested, though still refusing treatment, till one night we were sent for in great haste, and Dr. Chrystie responding, found her in great agony with the interrupted muscular spasms, which are so distressing a feature in certain conditions during this disease. An abscess afterwards developed, and the case terminated in ankylosis.

The significance of sudden relief from a paroxysm of pain is very often misunderstood. When a patient applies to me saying, that he has been in great suffering, but at such or such a time became suddenly better—that is, was suddenly relieved of his pains, more or less completely, and has been gaining since—I am very apt to put a different interpretation upon the circumstance than the patient. I am very apt to make the parents understand that the supposed improvement is delusory; that the sudden relief, in the absence of other assignable cause, was occasioned by the escape of fluid from the joint, with freedom from the internal pressure of such fluid, and that an abscess within three, six, or nine months is to be expected, for such has been the rule in my experience. I have intimated that for purposes of diagnosis the chief reliance is to be placed on the touch—the educated touch. It is the quality of the motion, rather than the amount of it, which we need to determine. It is the character of the resistance which has diagnostic significance. The leg may be moved with comparative ease in all directions, and to the fullest extent; but if that is the only fact observed, it signifies nothing and determines nothing, in a large number of cases. Striking on the heel or knee, or pressure over the joint to see if it produces pain, is of still less value. Of

course there are plenty of cases where such a procedure would cause pain; but such pain or soreness determines nothing, and there are many cases of active disease when any reasonable force would not cause sensible pain. It is also a manipulation which may do harm, and ought to be rejected as utterly worthless in a diagnostic point of view.

The following case will illustrate the importance of appreciating, by the touch, delicate qualities of motion.

Mrs. S., of Newark, N. J., was first seen March 26, 1874. In October, 1872, seventeen months before, she was very ill with typhoid fever which lasted for twenty-one days. Was very much prostrated for a long time and unable to move head or hands, and it was spring before she could be got into the upright position. Had a great deal of pain running from knee to hip, and had never been able to bear weight on the left leg. The muscles of both lower extremities were contracted and rigid, both thighs and legs flexed, but the left much more than the right. The left was also strongly adducted across the pelvis. The right hip we pronounced sound, but the left joint exhibited unmistakable evidence of disease. There were commencing adhesions in the joint; in fact, incipient ankylosis existed, and we gave the lady and her husband to understand that a stiff joint could not be avoided. We would undertake to put the thigh, which was badly flexed and adducted, in a better position if they would be satisfied with that; but that was all we could lead them to hope for in regard to the left leg. The contraction at the right knee and hip could no doubt be wholly overcome and that leg fully restored. With regard to the condition of the left hip-joint I have no doubt that the injury was due to muscular compression while she was in an impoverished state of health. Muscular spasm is not an unfrequent occurrence, and I have known dislocations and other injuries to the joint to arise from this cause during severe typhoid attacks. The motion at the left hip was restricted, but easy enough to make. Now, that being the case, what caused me to think that adhesions had commenced in that joint?

This knowledge was gained purely by the sensation imparted to the fingers while balancing the leg delicately in the hand. A ponderous oaken door, swinging on well-oiled hinges, imparts a sensation of smoothness to the hand that moves it, quite independent of and distinct from the resistance it offers; while a light pine weather door, closed by a spring, though yielding to a gentler touch, imparts a clear and true sensation of a bending substance. So in this case, with my hand at the knee I could feel the resistance at the joint, and could determine that it was not muscular, and that the resistance, though slight, was in the joint. The result has proved the correctness of my diagnosis. There is now ankylosis in the left hip-joint, as predicted.

You will find this case reported in the *MEDICAL RECORD* for May 1st, 1874, under the title of "a Case of Muscular Contraction and Deformity Simulating Hip-Joint Disease." It was a clinical lecture by an eminent surgeon, delivered in Bellevue Hospital, some two weeks before this case applied to us.

But, though I believe the condition within the joint may be much more readily determined through direct sensation by delicate manipulations than by anything approaching violent handling, it is still true that the relative condition of the muscle affords the most sensitive guide to indications for practical treatment.

If I dwell on this subject at wearisome length, it is because I would give the inexperienced the key to suc-

* I use the words "lame" or "lameness" in this essay to describe a faulty walking, and not to imply a painful walking.

cessful diagnosis in this class of cases where failure in diagnosis is often so disastrous to the patient. Please bear with me while I introduce another case more in illustration of this branch of our subject.

S. G., of Mobile, Ala., eight years old, daughter of a physician, applied May 20, 1874. She was what might be called a "good case." Her father, then attending lectures in New York, had been written to that his little daughter had had various attacks of "rheumatism" from time to time during the several preceding months, and there was just a perceptible lameness.

The father divining the cause of the difficulty, had her brought to New York, and placed under our care. At that time she complained of nothing whatever, and it was difficult for the unpracticed eye to discern any defect in walking.

Examination revealed the stiffening of the muscles, which is so characteristic of inflammation in the hip-joint, though ordinary motion was painless and could be carried to very nearly the natural extent. Treatment was at once begun and pursued in the usual way, with decided benefit from the first. That is, the muscles relaxed and motion in the joint was less obstructed than before, but I was troubled to account for the fact that the muscular relaxation was not total, and motion in the joint was not so completely free as I had reason to expect in a case taken in so good season. Thus the case went on, for six months or more, without one untoward symptom except the barely detectable incompleteness of muscular relaxation before mentioned. Then an abscess was discovered directly above the trochanter major. The child was quite fleshy, and this abscess had been burrowing beneath the muscles, where it had exerted a certain amount of pressure within the joints. This internal pressure, extension of the leg of course could not remove. Hence a certain amount of stiffening or reluctance to relax remained in the muscles, notwithstanding efficient counter-extension. The abscess was promptly opened and complete relaxation followed quickly after the discharge of the pent-up fluid. The abscess soon healed. There is now complete relaxation of the muscles and perfect motion in the joint.

In differentiating between muscular contracture and persistent, uniform muscular contraction, no inference can be safely drawn from the length of time during which a condition has been maintained. We may accept it as the rule that while there is disease there will be active muscular contraction, and while there is active muscular contraction we may take that fact as a sure indication of disease. Furthermore, while there is motion in the joint, no matter how slight and restricted, there will never be complete loss of muscular irritability and contractility. But, on the other hand, so soon as motion in the joint is utterly prevented from any cause, and the disease has subsided, so that there is no direct or reflex irritation, the muscles pass rapidly into the passive mechanical condition called contracture, irrespective of the length of time it has required to arrive at this stage. Almost the whole diagnostic art, then, in these cases resolves itself into the ability to detect delicate shades of muscular conditions and otherwise imperceptible amounts and qualities of motion, which, when clearly made out, in kind, quality and degree, carry absolute conclusions regarding diagnosis, treatment, and prognosis.

It is surprising for how long a time a case may remain in the same relative condition, after a certain period has been reached.

A young lady, eighteen years old, from Williamsburgh, Miss P., had had double hip-joint disease, as she

said, all her life. For at least ten years, according to the account, she had walked with the knees in forcible contact, thighs flexed to an angle of 75 degrees or more, body bent, hands resting on two sticks, and progression made entirely by movements at the knee; and yet the joint on one side was good, and after stretching the muscles and restoring their action, she now stands upright and can take steps of almost the natural length, moving at the hip. Of course, there may be necrosis in the vicinity of the hip-joint, which may involve the muscles of the thigh in their influence, and we may have contractions which distort the position similar to that produced by disease of the joint. Disease of the lower dorsal and of the lumbar vertebrae, by causing contraction of the psoas muscle, will flex the leg, sometimes with adduction, and even be accompanied with a sensitiveness to manipulation which might be mistaken for evidence of disease of the hip-joint. But there ought to be little difficulty in distinguishing between the action of the flexor muscles alone, as when the psoas and iliacus muscles are irritated, and contractions which involve all the muscles concerned in movements of the femur.

Besides, the aspects of the two cases are strikingly dissimilar. When there is disease of the hip-joint the forward curve in the lumbar spine is increased, while in incipient spinal disease there is likely to be a straightening of the lumbar curve. The flattening of the natis on the affected side, and the conversion of the fissure between the nates from a vertical to a diagonal line may happen in both cases, and such change being often wanting in true hip-joint disease, and for other reasons, I regard it as of no importance as a means of diagnosis. When it exists the case can be made out perfectly well without that appearance. Its unreliable character should lead us to reject it.

This essay would not be complete without a few words upon the subject of so-called "hysterical joint," and some of the principal means of differentiating between the latter and true hip-joint disease.

Any one having much familiarity with joint diseases must have remarked the frequent recurrence of cases with painful and sometimes distorted joints, simulating in some respects disease of the joints to the inexperienced. The term "hysterical" serves well enough for the purpose of distinction, and was undoubtedly so called in consequence of its frequency in hysterical women. But it would be a mistake to suppose the painful joint without disease, to be confined to women or to hysterical women, although most frequently to be met with in unmarried women of a certain age.

But I have frequently met with it in children of both sexes, and, though less frequently, in adult males. There is a little girl in Brooklyn who has been brought to me regularly several times a year to be treated for hip-joint disease, to be as regularly sent home with the assurance that there was no disease of the joint whatever. She was a bright, nervous, delicate child, about seven years old. One day she saw a child lame with paralysis, and she immediately began to draw up her leg and to limp, and so she has continued to do for five or six years past. At one time she was treated by weight and pulley and recumbent position, for hip-joint disease. The leg was brought down readily enough, and after three months' confinement with the leg in the natural position the case was pronounced cured.

The attending physician, who related the circumstances to me, said you may imagine my surprise, when, after gathering the family to see the wonderful cure, on letting her up to see her start off on her feet, walk-

ing exactly as she did before her confinement. We have a patient under treatment for another disease, a boy, ten years old, who has walked lame, with his leg drawn up similar to the position assumed in hip-joint disease, for several years past, whereas there is no disease of the joint or muscles. Any form of treatment by directing the attention towards the part treated, only aggravates such cases.

Both the above-mentioned cases are now nearly well, and both began to improve not long after they were left severely alone, so far as their joints were concerned. But this is not so easy when a young lady applies to you with a painful joint—perhaps has come a long distance with a letter of introduction from her family physician, expecting you to put her into a splint and make a brilliant cure of her case. To tell her and her friends that there is no joint disease, and that this symptom depends on a general systemic condition, even if you succeed in avoiding the use of the word "hysteria," is very apt to be unsatisfactory, if it is not positively offensive.

This subject is very attractive to me, but I can stop only to call attention to the more prominent points of difference between an hysterical hip-joint and a true hip-joint disease. Of course, this comparison can apply only to a diseased joint at an early stage where the positive indications are more or less obscure.

In the first place, in hysterical joint there is generally excessive sensibility to the first contact of touch, rather than to motion, after the leg is fairly grasped. There is variability instead of general uniformity of character and amount of lameness in the same day. There is indefiniteness in regard to location of pain or soreness on motion, and there is the appearance and general history of the patient.

But here again, the best evidence of the nature of the difficulty complained of, is to be obtained by the sensation imparted to the hand of the experienced examiner. By a little management and patience, and perhaps several examinations, the subject's attention may be diverted so that we can very readily perceive that a large part of the muscular action is under the control of the will, which, of course, is diagnostic of the hysterical condition.

But there is another class of cases where I confess it is not so easy to make out the exact condition, under all circumstances. It is when we have real inflammation of the joint in a highly nervous and hysterical subject. While one should be on his guard against accepting appearances for realities, we must not, on the other hand, run into the opposite extreme by the assumption that because the subject is evidently hysterical she cannot have hip-joint disease. As a clinical fact we find a due proportion of cases of disease of the hip-joint among this class of subjects. And it thus happens that an actual disease may act as the disturbing element in the display of a large amount of nervous phenomena. Such cases are constantly occurring, and they require the most careful management and the exercise of judicial patience, in order to justly discriminate between those symptoms which flow directly from the disease, and those generally more demonstrative manifestations depending primarily on a hysterical constitution, and only secondarily on the local disease as an exciting cause. It is never safe to "jump at conclusions," or to think we know our case whatever our first impressions may be, till after we have fairly made it out by patient investigation.

SCHOOL HYGIENE is being made the subject of a formal inquiry in Davenport, Iowa.

SALICYLIC ACID AS A THERAPEUTIC AGENT.

By A. MEAD EDWARDS, M.D.,

NEWARK, N. J.

EVER since the attention of the medical fraternity has been called to the subject of salicylic acid, I have watched the journals for records of its use and success, since many years ago, as a chemical student, I experimented chemically with the substance, and always felt that some day a useful practical application of this hitherto neglected substance would before long be found. It has remained for our German brothers, as usual, to point us a way, and I trust it will naturally follow that we Americans will outstrip our teachers. As early as possible I have put salicylic acid on trial, with the following results: On the evening of the 25th March, I exhibited specimens of salicylic acid before the Newark Scientific Association, and suggested to the medical members present the desirability of trying it in diphtheria, not being at that time aware of the success attending its use in this disease abroad. Dr. G. A. Van Wagenen took some, and the succeeding Saturday morning I received the following note from him, dated the night before:—

"DEAR DOCTOR—When I received specimen of salicylic acid I hardly thought an opportunity would present so early to test its virtues. Before I left home yesterday evening one of my patients came to the office for some of the mixture of iodine, carbolic acid and glycerine, saying that her sister had been suffering from sore throat all day; that her mother had painted her throat with tinct. iodine; and, as it was no better, wished to apply what I had used in two other cases in the family. She said she would let me know in the morning (that is this A.M.) if there was no improvement, and if so would like me to see it. The solution was used once last night and once this morning; and about 10.30 I was called, no improvement having taken place. On examination, glands at bifurcation of carotid enlarged and tender, tonsils and pharynx swollen and reddened, with a delicate white membrane distributed in patches over whole pharynx and soft palate, and coming forward over the edge of the hard palate into the mouth; tongue deeply coated; temp. 102.2° F., pulse 120; face flushed, headache, pain in bones, and great prostration, etc. I give the history in order that you may know whether I made a mistake when I called this a case of diphtheria (non-malignant), and that you may have an idea of the test to which the acid was put. The delay had given time for the case to get under way, as the mother acknowledged herself. I suspended 2 grs. salicylic acid in 1 dr. glycerine (it would not dissolve with the moderate heat I used), and at 11 A.M. carefully painted over the whole throat, using 15 minims of the glycerine (gr. $\frac{1}{2}$ ac. salicylic). Also dissolved 5 grs. of the acid in a pint of water, to be used as a gargle every twenty minutes or half an hour. At 1.30 P.M. her mother examined the throat, and says she could see no membrane. As soon as I finished my calls I went back to see what effect had been produced, and at 5.30 the pharynx and palate were entirely cleaned, leaving a very bright red surface. Only a very small patch remained on the back part of the right tonsil, which I may not have thoroughly reached. I reapplied the acid and continued the gargle. Nothing else was used with, or in connection with, the acid. I had hardly hoped for so early and favorable a report. I will send you the case in time."

Subsequently he told me the lady recovered entirely in a day or two.

A few days after I was called to see a lady, who complained of a severe sore throat, with the following symptoms: Pulse 100, temperature 99.4° F., tongue very much coated, great prostration, with severe pains in the back and down the arms, and especially in the back of the hands, with great headache. The sense of stiffness of the neck spoken of by authors when treating of diphtheria was very apparent, and was shown in the erect position maintained by the patient as she sat in her chair, and she also characteristically expressed the fear that she had caught a cold in her neck. There was considerable difficulty in swallowing, and an examination showed the tonsils to be covered with large whitish patches of the characteristic diphtheritic type. The rest of the mucous membrane, far up into the hard palate, was of a deep red hue, and considerably swollen. As the patient gave me a history of malaria, eight grains of sulphate of quinine in powder, followed by about twenty-five grains of bromide of potassium, were at once administered, and a gargle of a saturated solution of salicylic acid in water given, to be used as often as convenient. She had not slept the night before, and the night after I saw her she was kept awake almost until morning, during which time the gargle was freely used. The next morning I saw her, and all the white patches but one were gone. A solution of salicylic acid in glycerine, diluted with water, was given in a hand atomizer, and directed to be used every hour during the day, and the quinine and bromide to be repeated at night. That evening when I saw her the throat was quite clear, and the angry and swollen appearance of the mucous membrane had very much subsided. The next day she was convalescent, and two days after expressed herself as feeling perfectly well.

Dr. Archibald Mercer, House Physician at St. Barnabas Hospital, to whom I had given a sample of the acid for experiment, reported as follows:

"MY DEAR DOCTOR—Many thanks for your specimen of salicylic acid. I have used it in two cases with most unhopd-for success. 1st, a fracture of the tibia and fibula, comp. by the protrusion of the lower fragment of the tibia through the integuments. I endeavored to convert it into a simple fracture by the free use of collodion and only partially succeeded. At the end of the second week the opening began to suppurate and I was obliged to remove my collodion cover, leaving a mass of granulations nearly an inch square. In a few days an abscess formed under this mass, and just after I had opened it I used your acid. I sprinkled the dry powder over the mass of granulations, and the next day I had a hard crust about one-quarter of the size of the original mass. And since then I have given it no attention. One application cured.

"2d. Large granulating surface following sloughing of toes from frost-bite. In this case the acid is most rapidly diminishing the size of the surface, at the same time nearly completely preventing suppuration and relieving parts completely of all bad odor (there being a slight necrosis of one of the phalanges).

"I have used it with very marked success in several cases of uterine disease; all foul odor present in the discharges is removed at once, and so-called ulcerations upon the os have disappeared after the use of one pad of cotton containing a grain or two of the acid and steeped in glycerine. A case of vaginitis in a woman of 68 was markedly improved, and a case of eczema cupritis of great severity and long standing seems to have changed for the better under its use."

I trust that the importance of the subject will be sufficient excuse for the disconnected character of this communication, and that the profession at large will

give this new drug a fair trial and let us know what it will do.

Dr. Clark, of Belleville, to whom I gave a sample of the acid, reports very favorably of its use in the form of a powder in a severe case of bed-sores.

ZEISSL'S METHOD OF INTRODUCING LIQUIDS INTO THE MALE BLADDER WITHOUT THE USE OF THE CATHETER.

By A. ROSE, M.D.,

NEW YORK.

As the use of the catheter in injecting liquids into the bladder does harm to the mucous membrane in hemorrhage, a new method has been invented by Dr. H. Zeissl, of Vienna (*Wiener med. Wochenschrift*, 1874, Nos. 51 & 52). He simply fits the point of an irrigator into the mouth of the urethra, while the patient is placed on his back, with raised nates, the penis being stretched along the abdominal walls.

I have employed this method on one of my patients under the following circumstances: M—K—, 60 years old, having retired from active business and leading a life of ease, is the father of a healthy and numerous family, having always been healthy, with the exception of a gonorrhœa contracted 40 years ago, was seen by me, for the first time, on March 22d, 1875. The patient complains for two weeks of frequent and painful micturition. The urine is turbid, and contains a large quantity of muco-purulent sediment. He is feverish, has neither sleep nor appetite. I tried to enter the bladder with a double catheter, but did not succeed on account of strictures. I then tried dilatation, beginning with a No. 6 steel sound, and finally succeeded in introducing No. 12. The first dilatations were painful, and followed by chills. In spite of the administration of quinine, and the hypodermic use of morphia, the patient claimed to have these chills still. He refused to let me make an incision into the strictures. On April 8th I introduced a double catheter, No. 10, which I connected with a fountain syringe filled with tepid water. Mucus and blood coagula filled one canula to such an extent that, while the water entered freely, it could return only through one channel. During and after the introduction of the catheter there was great pain and fever. I saw the patient again on April 12th. The urine was clearer, and but little sediment was found. For internal use I had ordered the bicarbonate of soda, and lime water with milk, and Vichy water, to be used alternately. Want of appetite and sleep still existed.

Having in the meantime read of Zeissl's method, I introduced a glass tube into the urethra, having first connected it with the India-rubber tube of a fountain syringe, which contained about eight ounces of a tepid solution of tannin, which I allowed to pass into the urethra from a height of four feet. The patient experiences, after half a minute, while the liquid entered the bladder, a feeling of comfort, just as described by Zeissl's patients. I removed the glass tube as soon as the liquid began flowing out of the urethra alongside of the tube. The patient, feeling a desire to pass the water, emptied a liquid containing mucus and tannin.

April 13th, there is a decided improvement in every respect; the urine is nearly clear, there being but a very small quantity of sediment. The patient has been able to sleep a few hours.

April 14th, renewed introduction of solution of tannin into the bladder.

April 15th, patient has slept better than ever since he took sick; has no fever; his appetite is returning; and he feels altogether encouraged. Steel sound No. 12 passed for the first time with ease and without leaving any pain.

Progress of Medical Science.

BASTIAN ON THE GERM THEORY OF DISEASE.—At the meeting of the Pathological Society of London, on April 6th, Dr. Bastian opened the discussion by an address on the germ theory of disease; viz., the causal relation between certain virulent inflammations or specific diseases, and the presence of low organisms in the affected tissues. He alluded to the two main theories in vogue; the one which ascribes the origin of such diseases to certain ferments, or substances allied to the ferments, which Pasteur had at one time believed and stated to be the cause of all fermentative and putrefactive processes; the other, the physico-chemical theory which Liebig had advanced more than twenty years ago, and which, as it may be stated at the present day, affirms that living organisms, though they may act as ferments, act in this capacity merely by virtue of the chemical changes which the carrying on of their growth necessitates; and that other chemical changes taking place during the decay of organic matter, may make fragments of it (in the dead state) almost equally capable of initiating fermentative changes in suitable media; while in either case bacteria or allied organisms are prone to be engendered as correlative products.

In regard to the special question, whether gonorrhœa, purulent ophthalmia, erysipelas, hospital gangrene, puerperal fever, pyæmia, septicæmia, and the like, are due to the presence of low organisms, he states the following facts in opposition to such a view: 1. The experiments of many investigators prove that the alleged causes of disease may be actually introduced into the blood-vessels of low animals by thousands without producing any deleterious effects in a large majority of the cases. 2. Bacteria, if not actually to be found within the blood-vessels of healthy persons, do nevertheless habitually exist in so many parts of the body in every human being, and in so many of the lower animals, as to make it almost inconceivable that these organisms can be causes of disease. In healthy persons they may be found in myriads in and about the epithelium of the whole alimentary tract from mouth to anus; they exist throughout the air-passages, and may be found in mucus coming from the nasal cavities, as well as in that from the minute bronchi; they are absorbed in immense numbers with the food; and lastly, in persons with open wounds, bacteria are constantly to be found in contact with such surfaces, especially if the wounds are not well cared for, though the injured person does not necessarily suffer at all in general health. 3. The argument that the bacteria of such diseases are different from those of health, has yet to be proved, while, on the other hand, it has been shown that the forms which these two organisms exhibit is probably due to the peculiar conditions in which they find themselves. 4. The virulence of certain contagious mixtures diminishes in direct proportion to the increase of the bacteria in them, and again, fresh and contagious menstrua lose hardly any of their virulence by being subjected for a few minutes to a temperature of 212° F., and after being boiled in alcohol, both of which experiments, the author states, are known to be destructive to all recognized forms of living matter.

The presence of bacteria in the fluids and tissues of diseased persons, Dr. Bastian explains by the fact that certain changes have previously taken place in the constitution and vitality of such fluids and tissues, and that bacteria and allied organisms have appeared therein as pathological products.

As to the question, whether the germ theory is applicable to artificial tuberculosis, syphilis, typhoid, typhus, relapsing fever, cholera, measles, scarlet fever, small-pox, and other contagious fevers, the following statements are made: 1. With two exceptions, no definite germs or organisms are to be met with in the blood of patients suffering from these diseases during any stage of their progress. 2. The virus or contagion of some of these diseases, whatever it may be, does not exhibit the properties of living matter. 3. The virus of most of these contagious diseases with which definite experiment has been made, is most potent in the fresh state, while its power diminishes in intensity as organisms reveal themselves more abundantly in it. Reference is made to the facts mentioned by Obermeier, that the blood of relapsing fever patients exhibited spirilla, and to the statements of Klein, who claims to have discovered certain peculiar bodies among the lesions of typhoid fever, especially in Peyer's patches, while there are two diseases, sheep-pox or ovine small-pox and splenic fever, a disease occasionally communicated to persons from cattle, where it is now said there are certain low organisms in the tissues that appear to have some causal relation with the diseases. Our present notion of zymotic or ferment disease must, however, according to Dr. B., be subjected to modification, if we regard such diseases as due to the operation of low organisms in the sense that Pasteur claimed fermentation was due to the multiplication of such agents. The real fact is, that Pasteur and his followers have modified these views so considerably, that it is now acknowledged that such organisms are not essential factors in fermentation, and, indeed, such processes may go on quite independently of them; fermentative changes are produced under the influence of altered chemical processes taking place in unhealthy vegetal tissue.

Some such chemical action, it is suggested, may be at work in these diseased processes, and some of the complex compounds may be thrown off, and act as contagious principles.—*The Lancet*, April 10, 1875.

STATISTICS OF A HUNDRED CASES OF OPERATIONS FOR STONE.—Sir Henry Thompson has given a brief record of his last hundred cases of operation on the *adult*, excluding all cases below 22 years of age, of which there happened to be one. There are in the list only four cases below 50, sixty-five cases being above 60, and the mean age of the entire list of cases being not less than 63½ years. The first operation of this series was done shortly before Christmas of 1872, and the record represents all his work in this direction for two years and a quarter, the case of the Emperor Napoleon being the third of the series. Ninety-six were adult males, and four were adult females. Of the ninety-six males eighty-seven were operated on by lithotripsy, and nine by lateral lithotomy.

The mean age of the eighty-seven operated on by lithotripsy was 63½ years, the oldest being 83, the youngest 22, but only four were below 50 years.

The mean age of the nine operated on by lithotomy was 63½ years also, their ages being also between 36 and 79. Among the eighty-seven operated on by lithotripsy were four deaths; the ages were 65, 65, 66, and 81. Among the nine operated on by lithotomy

were two deaths, viz., at 61 and 63. Thus it is observed that there was a total of six deaths in ninety-six patients, by the two operations, with a mean age of 63½. In this series allusion is made to what may be termed an extraordinary run of luck. It was a succession of fifty-one elderly cases without a single death, these cases having a mean age of 64 years. The author states that he hopes soon to publish his experiences in an unbroken series of 500 cases in the adult male, besides the cases of women and children.—*The Lancet*, April 3, 1875.

ADDISON'S DISEASE.—Dr. Greenhow, in his Croonian lectures at the Royal College of Physicians of London, has given us the results of a careful revision of over 300 reported cases of this disease of the supra-renal capsules. He found that the clinical phenomena which Addison associated with the peculiar lesion of the capsules were of very frequent occurrence, as evidenced by post-mortems in 228 of the cases. He describes the constitutional symptoms as mainly those of progressive asthenia, great languor, and indisposition for exertion, cardiac weakness, loss of appetite and gastric irritability, pain in the loins, epigastrium, and one or both hypochondria, while there is no emaciation, but often, on the other hand, a considerable excess of fat; the temperature is usually below the normal, the skin being cool, if not cold. The skin has a dusky, smoky, or yellowish-brown hue, but sometimes it is of an olive or green-brown color, or approaches in parts to the tint of negro skin. The discoloration is never uniform, but commences earlier and becomes deeper in the more exposed parts, and also in those parts where there is usually an excess of pigment. Sometimes there appear to be remissions and then constitutional symptoms and the discoloration of the skin disappear. Such alternations may take place several times before the fatal paroxysm, but on each occasion the patient takes one downward step that he never regains.*

In typical cases of the disease he generally found the capsules enlarged, hard, and nodulated, though in rare cases their size was normal, or even less than normal. On section they scarcely ever presented any trace of the distinction between cortex and medulla. In fresh specimens the cut surfaces had a marbled appearance, from the admixture of two materials of different consistence and color. One of these materials had a grayish, semi-transparent appearance on being freshly cut, but a pinkish hue at a later period. The other material had an opaque-yellow, or cream color, and existed generally in the form of irregular, roundish masses of a more or less friable consistence, and was imbedded in the translucent tissues, from which, in many cases, it could easily be enucleated. These opaque, cheesy nodules were sometimes replaced by cretaceous masses, and then the capsules were smallest. Sometimes this material became fluid, making it appear as if there were abscesses, and, in fact, some observers had described them as such. The relative quantity of these two materials differed in different cases, and depended solely on the duration and intensity of the disease. The translucent material consisted of a fibrillated stroma, containing numerous lymphoid corpuscles; the opaque, cheesy matter consisted of amorphous, granular matter, with an admixture of shrunken cells, nuclei, and oil. In his own cases the capsule was thickened and was united by adhesion to neighboring organs, such as the liver, pancreas, kidneys, stomach, while the nerves of the supra-renal and solar plexuses had a thick, fibrous investment. He had also observed changes in the lymphatic glands of the neighborhood, and changes in the glands of the

intestines and stomach. He does not think that the enlargement of the spleen was of constant occurrence.

Of all these cases 101 were regarded as typical, because in them the train of constitutional symptoms and the peculiar change of color in the skin was observed, and the disease was found in each instance, by post mortem examination, to correspond with the particular lesion already described, and in no one of these cases was there any other organic disease of any consequence. The author believes that a large measure of the doubt that has prevailed in regard to the existence of this affection as a distinct disease has arisen in part from the fact that Addison himself included in his list of cases some that were not real examples of it, while cases of pityriasis versicolor, syphilis, etc., have sometimes been mistaken for it; and further, the results of post-mortem examinations have not been correctly interpreted.—*The Lancet*, March and April, 1875.

SLOWNESS OF PULSE.—At a recent meeting of the Clinical Society of London, Mr. Thornton narrated the history of a case in which the pulse was so infrequent as at one time not to average more than sixteen beats per minute, while for several weeks together there were never more than twenty-four beats in the same time. The patient was a young married woman, upon whom, in 1872, he had performed tracheotomy for syphilitic laryngitis. Her pulse at the time of the operation was forty, and it was not until six weeks after, when the tracheotomy tube was removed, that the extraordinary slowness of the pulse was noticed. This infrequency had been accompanied by transient attacks of an epileptiform character. It appeared that she was first seized with these fits in the summer of 1870, the attacks happening daily for about two months, and the pulse averaging about twenty-four pulsations per minute. At the time of the narration her pulse was constantly at forty-eight, and the woman was in good health, except that at periodic intervals she was obliged to take iodide of potassium to abort an attack of laryngitis. Mr. T. offered no explanation of this curious phenomenon other than that the pneumogastric might have been affected by the specific poison. Mr. Callender stated that he had recently observed a pulse of thirty-two in a very robust man under his care. A case was alluded to which had been reported in an early number of the *Medico-Chirurgical Transactions*, where a pulse was observed to have ranged between twenty-five and seven. At the post-mortem examination it was found that the foramen magnum was so small that it would barely admit the tip of the little finger, and there was hypertrophy of the superior cervical ganglion of the sympathetic nerve.—*The Doctor*, April 1, 1875.

MERCURY IN SYPHILIS.—Dr. Drysdale, one of the most active opponents of mercury in syphilis, has recently had the courage to state that he has altered his views, and now believes that in many cases of primary and secondary lesions mercury may be used with benefit. His own prolonged treatment of secondaries with the iodide of potassium has taught him that the appearance of tertiaries is not mainly attributable to the abuse of mercury, but rather that it is apt to be induced by dissolute habits, constitutional vice, old age, and the like. He agrees with Fournier that judicious courses of mercury are very potent in warding off the tertiary stage. In the treatment of these later forms he believes that great reliance may be placed upon the iodide of potassium, or the iodide of iron, which he finds all-powerful agents, though at the same time he infers that in rupia and pustulo-crustaceous forms mercury is of signal service.—*The Doctor*, April 1, 1875.

MEDICAL LEGISLATION IN NEW JERSEY.

THE course of legislation in New Jersey in reference to matters of medical and sanitary interest has been such the past winter as to require some attention on the part of medical men. It was the intention of the Sanitary Commission to offer a bill to both Houses for the establishment of a State Board of Health. When the bill had passed the Senate and came to the Judiciary Committee of the House, the homœopaths appeared in full force to oppose the bill, unless at least three of their school could be named upon it. In that case they were ready to offer their own names on the bill, and objected either to leaving it to the Governor or Supreme Court to appoint. It is well known that these men embrace every opportunity to legislate themselves into position.

The bill did not specify that any of the Board should be physicians, and the Commission very properly claimed that it was not a bill for legislating any class of men into position. Although physicians or druggists, or persons who had served on Health Boards, might thereby be better fitted for service on such a Board, yet there was no reason why the State should recognize different sects of medicine in a bill for the public health, or specify the occupations of the Board. It was evident, from the construction of the Committee and the predilections of the majority toward irregular medicine, that if they reported the bill they would force some such amendment. So the Commission preferred to let the State wait for proper sanitary legislation rather than to recognize a Board on such a basis. It is not claimed that a homœopathic or botanic physician is by his vocation debarred from such a board, if the Governor found in such a one a proper sanitary officer, but it is claimed that no sect shall thus be allowed to legislate itself into place, and that a bargain, in which four of the old practice and three specialists nominate themselves for place, is a kind of

coalition not productive of health interests. Hudson, too, a year or two since, made some such arrangement, which does not bring forth good fruit. Their highest ambition seems to be to tax every corpse twenty-five cents for passing through the County, and to compile vital statistics, which they well know, without a system in the State, is of no practical value. Yet they have succeeded in spending several thousand dollars of the public funds, and are not endorsed by the best physicians of the County.

A general registry bill which was introduced also had a strange history. After passing to a second reading, it could not be found, until one day it made its appearance on the floor behind the speaker's desk, where it had been innocently mislaid, and was thus discovered too late for passage.

In the meantime the *Eclectic* school of medicine, consisting of men and women, had a bill introduced authorizing them to license and practise. With this the regulars interfered but little. They took the ground that as the old practice had several years since relinquished all special chartered rights, they had but little interest in the method. On the other hand, the homœopaths, who had procured a charter some few years since, seemed jealous of this sect of eclectics, which is quite as respectable as the former, and secured the defeat of their bill. The homœopaths claimed that they are very particular to have no one practise without a diploma. How little this means we all are aware, because we know how much a diploma from some colleges is worth.

In the meantime another bill coming from Hudson County was introduced to appoint for the State a Board of Examiners with sole power to license, consisting of homœopaths and regulars, to constitute a board, each examining its own sect. Under the guide of the pliant Chairman of the Judiciary Committee of the House it was passed there, but was quickly defeated in the Senate. The whole course of legislature on medical matters in New Jersey has been quite instructive. The old profession of that State has eminent respectable men; is made up of many of the best graduates from New York and Philadelphia, and is ever alive to the progress of the art of medicine. It is in vain that the "mongreis" talk of it as old-fashioned, and represent themselves as new and progressive. The attempt to designate the regulars also as allopaths is a failure. They claim to be antipaths, and adopt this as their true title, because opposed to suffering, and doing all they can to overcome it. They are not practitioners of any system which asserts that contraries are cured by contraries. While homœopaths and eclectics, of course, secure some practice, and now and then one of them rides into style and wealth, yet there is a want felt of general respectability and recognition. This they propose to supply by legislation, instead of showing by their contributions to science their ability to entitle themselves to be classed as a scientific profession. Hence not even a sanitary matter

can be brought forward unless in some way they seek through it professional recognition. We believe that the joint interests of the public and of the profession indicate that but little should at present be attempted in the line of medical legislation. Our legislatures are not sufficiently informed as to the merits of any particular system, nor are the people prepared to accept any special State endorsement of any school. The people must be left to find out in this as in other departments where and how they can be best served, and must make their own choice as to who shall attend them in sickness.

But all this should not in anywise interfere with sanitary legislation. The prevention of disease is far more eminently and practically the care of the government than is its treatment. There is no possible reason why, when a bill relating to public health is introduced, which does not even specify physicians, a host of sects should stand and ask for special legislation and recognition on their behalf. The readiness to bargain shows place-seeking, and the readiness to seek defeat unless bargain can be made, shows how little real interest such men have in sanitary matters. Thus sanitary legislation is delayed, and the people suffer. The only selfish consolation is that we doctors have more to do. If the people can stand it, we can. As citizens and as philanthropists we are sorry. As physicians we are consoled, because it makes business brisker, and we have better opportunities for the study of pathology.

There were possibly four of these cases which died from hip-joint disease; but whether they would have been saved by exsection he did not know. If any would have been saved by the operation, perhaps so far he had neglected his duty; but hip-joint disease is a very curable disease.

DR. PEASLEE asked Dr. Taylor whether, if he was aware that the head of the femur is necrosed, he would remove it or not?

DR. TAYLOR replied that he did not object to its removal, but that they had had such favorable results in the treatment of such cases when it had not been removed, and had found that such patients do not die but get well, that the operation had not been resorted to. Either it so happened that they do not have bad cases, certainly do not see cases which would be improved by the operation, or else the operation was many times performed when it was unnecessary. That exsection was carried too far he had no doubt, but that there are cases in which the operation would be justifiable he does not deny; yet he had not seen such cases. He had, however, seen cases of hip-joint disease in which there was free discharge of pus from the joint, together with pieces of bone, and yet the patients have recovered with a good joint.

DR. PEASLEE. Then you have such cases?

DR. TAYLOR. Oh, yes, we are having such cases constantly.

DR. GARRISH remarked that all the cases of hip-joint disease he had seen had been the result of injury, and he was of the opinion that we never have the disease occurring spontaneously.

DR. TAYLOR remarked that he regarded it as of very infrequent occurrence except as the result of injury, but that it is possible for the disease to occur independent of an injury, he is convinced, and believes it is going too far to say that it never occurs from any other cause.

Reports of Societies.

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting, April 16, 1875.

DISCUSSION OF DR. C. FAYETTE TAYLOR'S PAPER.

DR. GARRISH asked Dr. Taylor if he recommended the operation of exsection of the hip-joint?

DR. TAYLOR replied that he had been looking for a case which would justify the operation, but had not yet found one.

DR. GARRISH asked if he understood the doctor to say that he did not approve of tenotomy?

DR. TAYLOR replied that he does not object to tenotomy, but that it is not necessary when the muscles will relax; but in cases where either cutting or tearing must be resorted to in order to overcome muscular action, he preferred to tear rather than cut the muscles and tendons.

With regard to exsection he further remarked that he could do no better in answering Dr. Garrish's question than to present some statistics made up from the dispensary.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 14, 1875.

DR. F. DELAFIELD, PRESIDENT, in the Chair.

FATTY HEART, WITH FEW SYMPTOMS DURING LIFE.

DR. SATTEITHWAITE presented a specimen of fatty degeneration of the heart, which was rather interesting, in connection with a few prominent symptoms that the patient had during life. The history was obtained from the attending physician, and Dr. Sattethwaite was present at the autopsy. The patient was a gentleman seventy-one years of age, who had led a very active life, and had been in a very healthy condition. The only trouble that he had, so far as was known by his family physician, was an attack of acute rheumatism, which, however, passed away rapidly, without leaving any ill effects.

About one year ago he was travelling in California, and in walking up and down the hills during his short excursions, he noticed that he was short-winded. This inconvenience, as it was only temporary, did not give him any anxiety. About seven weeks ago he took a twenty-five mile sleigh-ride, and on returning he felt very weak. A little stimulus soon revived him, and he felt better. About five weeks ago, while riding up home in a horse-car, he partially lost consciousness, but by the help of some one he found his way home. His wife, finding him in a weak and confused condition, administered some stimulants with a good result.

The family physician was then sent for and pronounced the patient in a very weak and anæmic condition. On examination the heart was found to act very feebly, the beat being scarcely appreciable at the apex. His pulse could not be felt at all. His urine was examined, but neither casts nor albumen were found; it was from 1002° to 1018° in specific gravity. His pulse could not be felt at all. Tonics and stimulants were administered, with, however, no effect, and he gradually failed and died.

At the post-mortem examination the first noticeable thing was the skin of the patient, which was of an unnatural whiteness. The patient was well provided with fat. On opening the thoracic cavity the lungs were found to be marked by œdemas. The pleural cavities were filled with bloody serum, as was also the case to a limited extent with the pericardium. The heart itself was not specially enlarged, but was very pale and flabby. There was no trouble about the valves. The aorta was somewhat atheromatous.

It was very evident, in looking at the left ventricle, that it was very fatty. In the right ventricle this condition was not so much marked. A microscopical examination confirmed the conclusion in regard to the pathological condition alluded to. On the inner side of the left ventricle the markings of the muscular tissue were entirely gone, but on the periphery of the heart the muscular tissue was less fatty.

The liver was small, but not fatty, and the cells were large and granular. The kidneys were remarkably pale, fatty, and friable, particularly the right, the upper portion of which was particularly soft. This latter condition was due to a parenchymatous degeneration of the tubes. It was hard to recognize any cells whatever in the tubes of the lower portion of the right kidney.

The interest of the case seemed to be connected with the existence of fatty degeneration of the heart of a well-marked character, and yet without any prominent symptoms during life.

DR. DELAFIELD thought that it was oftentimes very perplexing to determine how much degeneration of the heart fibre was sufficient in a given case to cause death. In some cases a very moderate amount of degeneration was the only recognizable lesion, while in others the heart was extremely fatty.

DR. LOOMIS remarked that the size of the heart cavities had a great deal to do with the cause of death. When there was a great deal of dilatation, a very small amount of attendant fatty degeneration might be a sufficient cause for death, and *vice versa*. Wherever there was a feeble action of the heart, and indistinct first sound, indistinct apex beat, with increased area of dulness, the prognosis was apt to be unfavorable, but where there were no evidences of dilatation, the chances for living were good.

DR. DELAFIELD remarked that dilatation always attended fatty degeneration, and one condition was usually a mark of the other.

MISCELLANEOUS SPECIMENS.

DR. MESSENGER presented specimens of interstitial nephritis removed from a patient aged sixty-four, with very obstinate rheumatic pains and persistent ascites.

DR. BURRAL, by invitation, presented a specimen of congenital laryngismus, after which the Society went into executive session.

LA PHARMACIE DE LYON is the title of a new pharmaceutical journal which is being published at Lyons, France, since the 1st of March.

Correspondence.

CASES OF HIGH TEMPERATURE.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In a previous issue is an excerpt from the *Lancet*, of March 6, on "Extraordinary High Temperature."

Thinking a brief statement of two cases of Pneumonia, which I have still under treatment (though now convalescent) might interest your readers, as regards temperature, I submit them. The first case, a girl aged 16 years, strong and full-blooded, had pneumonia of the left lung. Temperature began rising up to fifth day, when it stood, as carefully noted by a self-registering thermometer, 107.5. The sixth day it fell to 104° by evening. The condition of the patient otherwise showed no cause for alarm as far as consultation could decide. She is now about, and free from cough, and gaining her strength fast.

The second case was her brother Frank, aged 20 years. He was seen twelve hours after he began to complain. Pulse 165, wiry. Slightly, delirious. Examination reveals pneumonia of right lung. Temperature, *very carefully* taken thirty-four hours after I called, was 110°. I could not believe my eyes until I had repeated the experiment several times with the same result. The expectoration was nearly pure blood for forty-eight or fifty hours; cough harassing. Now here is a strange feature (to me) in this case: the temperature was 110° at 5 P.M., and next morning at 9.30 A.M. it had fallen to 99, or rather 98.08. Treatment: potas. iodid. and tr. aconite during the night. An intense diaphoresis occurred which continued for twenty hours.

Yours respectfully,

J. G. BACON, M.D.

SARATOGA SPRINGS.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 25th to May 1st, 1875.

SLOAN, WM. J., Surgeon.—When relieved by Surgeon Head, to report in person to the Commanding General Department of Dakota for duty as Medical Director. S. O. 73, A. G. O., April 23, 1875.

HEAD, J. F., Surgeon.—To report in person to the Commanding General Department of the South, for duty as Medical Director. S. O. 73, c. s., A. G. O.

BYRNE, C. C., Surgeon.—Transferred from Willet's Point, N. Y. H., to Department of Dakota. S. O. 73, c. s., A. G. O.

BACHE, D., Surgeon.—Relieved from temporary duty in Baltimore, and to resume his duties at Fort Meigs, Md. S. O. 76, A. G. O., April 28, 1875.

FRANTZ, J. H., Surgeon.—Transferred from Department of the South to Military Division of the Atlantic. S. O. 73, c. s., A. G. O.

WEEDS, JAS. F., Surgeon.—Transferred from Department of Dakota to Department of the South. S. O. 75, A. G. O., April 27, 1875.

WOLVERTON, W. D., Assistant Surgeon.—Transferred from Department of the South to Department of Dakota. S. O. 75, c. s., A. G. O.

GIBSON, J. R., Assistant Surgeon.—Transferred from Department of the South to Department of the Platte. S. O. 73, c. s., A. G. O.

O'REILLY, R. M., Assistant Surgeon.—Relieved from duty in Department of the Platte, to report in person to the President of the Army Medical Board, New York City, for examination for promotion, and, upon its completion, by letter to the Surgeon-General. S. O. 73, c. s., A. G. O.

MATTHEWS, W., Assistant Surgeon.—Transferred from Military Division of the Atlantic to Department of California, and prior to his departure, to report to the President of the Army Medical Board, New York City, for examination for promotion. S. O. 73, c. s., A. G. O.

MUNN, C. E., Assistant Surgeon.—Transferred from Military Division of the Atlantic to Department of the Platte. S. O. 73, c. s., A. G. O.

COWDREY, S. G., Assistant Surgeon.—Relieved from duty in Department of the Missouri, to report to the President of the Army Medical Board, New York City, for examination for promotion, and, upon its completion, by letter to the Surgeon-General. S. O. 73, c. s., A. G. O.

PINLEY, J. A., Assistant Surgeon.—Transferred from Military Division of the Atlantic to Department of the Missouri. S. O. 73, c. s., A. G. O.

BEDAL, S. S., Assistant Surgeon.—Transferred from Military Division of the Atlantic to Department of Texas. S. O. 73, c. s., A. G. O.

HAMILTON, J. B., Assistant Surgeon.—Transferred from St. Louis Barracks, Mo., to Department of the Columbia. S. O. 73, c. s., A. G. O.

Medical Items and News.

DR. E. G. JANEWAY has been appointed Health Commissioner in place of Dr. S. Smith, whose term of service expired. The appointment is an exceedingly good one, and cannot fail to be satisfactory to the profession of the City.

THE ASSOCIATION OF AMERICAN MEDICAL EDITORS held its annual meeting at the Galt House, Louisville, May 3d. The President, Dr. Edgar, editor of *The St. Louis Medical and Surgical Journal*, delivered his annual address on the subject of medical education. This gave rise to an interesting discussion, participated in by Drs. Davis of Chicago, Parvin of Indianapolis, Bell of New York, Cuthbertson of Cincinnati, and D. W. Yundell, of Louisville.

The following officers were elected for the ensuing year: President, Dr. Bell, editor of *The Sanitarian*, of New York; Vice-President, Dr. H. C. Wood, Jr., editor *Philadelphia Medical Times*; Secretary, Dr. F. C. Davis, editor *Chicago Medical Examiner*.

DR. D. W. CHEEVER has been appointed Professor of Clinical Surgery in the Faculty of Medicine at Harvard University.

VISITING PHYSICIANS TO THE PRESBYTERIAN HOSPITAL.—Drs. Samuel T. Hubbard, G. M. Smith, F. A. Burrall, and V. S. Wooley have been appointed visiting physicians to the Presbyterian Hospital.

NEW YORK HOSPITAL.—Mr. John C. Green, President New York Hospital, and Mr. Wm. Dennistoun, Treasurer, both died of pneumonia within twenty-four hours of each other. They were interred on the 3d instant.

THE NEW YORK ACADEMY OF MEDICINE will occupy its new building, No. 12 West 31st street, on Thursday, 20th inst.

TRANSFUSION.—According to the daily papers, Gen. Frank P. Blair, of St. Louis, Mo., is paralytic and has been the subject of transfusion. Six ounces of blood are reported to have been thrown into his veins with favorable results.

THE JEWISH HOSPITAL of Philadelphia is pronounced by the Agent of the Pennsylvania State Board of Charities to compare favorably with the best hospital in the land, and recommends its adoption as a model for hospitals of similar size and purpose.

DIPHTHERITIC MEMBRANE.—The physicians appointed by the Health Board of this city to make studies in the pathology of diphtheria, have requested us to say that they will esteem it a great favor if they can be furnished with fresh specimens of diphtheritic membrane, or granted opportunities to attend post-mortems in diphtheria cases. Scraps of membrane can be wrapped in a bit of moist wax, and this in gutta-percha tissue or oiled silk, and forwarded by mail to Dr. T. E. Satterthwaite, care of Allan Cummings, Esq., 442 Fourth Avenue, to which address also any communication may be sent.

GERMAN DIPLOMAS IN NEW JERSEY.—A question is now in abeyance before the County Board of Health of Jersey City with regard to the physicians practising in the county. It appears that a great many have diplomas from foreign countries, in Germany chiefly, and the Board have written to the various universities at which the physicians have been graduated, to inquire as to their right to practise. Seventeen letters have been written, but only twelve answers received, and these not at all satisfactory, as they assert that the names of those that have been submitted have not passed the State examination which enables them to practise in their own country.

PNEUMO-THORAX, by Austin Flint, Sr., M.D. The third of this series of American Clinical Lectures, published by G. P. Putnam's Sons, is at hand, and embraces some eighty-one pages. The substance of the lecture was given in clinics at Bellevue Hospital, during the Session of 1874 and 1875, and the subject is arranged under the following heads: I. Pneumo-thorax in Cases of Emphysema. II. Pneumo-thorax in Cases of Interstitial Emphysema. III. Pneumo-thorax in Cases of Circumscribed Gangrene of Lung. IV. Pneumo-thorax in Cases of Phthisis.

A PHILADELPHIA SCHOOL FOR NURSES.—W. H. Hutt, M.D., has established a school for nurses at 1017 Morris street, Philadelphia, which is designed to give instruction to women in nursing, and also to prepare and furnish food suitable for such sick persons as are unable to procure necessary diet.

THE MEDICAL DEPARTMENT OF HARVARD UNIVERSITY has established an examination for admission.

On and after September, 1877, all students seeking admission to the Medical School must present a degree in letters or science from a recognized college or scientific school, or pass an examination in the following subjects:

1. Latin. The translation of easy Latin prose. French or German will be accepted, however, as a substitute for Latin.

2. Physics. Candidates will be required to show such a knowledge of this subject as may be obtained from Balfour Stewart's elementary works on Physics.

The examinations will be conducted in writing, and in judging the work of the candidates the spelling, grammar, and construction will be considered.

Graduates in medicine will not be required to pass this examination on joining the school.

Original Lectures.

THE GENERAL PHYSIOLOGY OF THE MOVEMENTS IN THE BODY.

By J. W. S. ARNOLD, M.D.,

PROF. OF PHYSIOLOGY, UNIVERSITY MEDICAL COLLEGE, N. Y.
Phonographically reported for THE MEDICAL RECORD.

LECTURE II.

GENTLEMEN:—To-day we will continue the study of muscular phenomena. If to a healthy muscle a piece of red litmus paper be applied, it becomes slightly blue; that is to say, a muscle when, as far as possible, in the normal condition gives an *alkaline* reaction. This occurs when the muscle is at rest [experiment]. But if the nerve be irritated so as to produce a continued contraction or tetanic condition, then the blue test paper turns red as you see [experiment], showing that while the muscle was contracting the reaction has been changed from alkaline to acid. I place the muscle in warm water, so as to kill it, and then touch it with the test papers. After rigor mortis has been fully developed, the reaction is acid again [experiment]. From these experiments we conclude.

A muscle at rest and in a normal condition is alkaline. The same muscle during contraction is acid, and is also acid during rigor mortis.

A piece of perfectly fresh living muscle, viewed under the microscope, is quite transparent. Kill the same muscle and then examine it, and it is opaque. How is the change produced?

It is due to a coagulation that occurs in the muscle of certain albuminoid substances. This is the manner in which rigor mortis is produced. The normal structure of a muscle consists of the sarcolemma and its contents, namely, the muscular tissue proper, permeated by the muscular fluid. When the muscle dies, a coagulation of this fluid takes place. It is on account of the coagulation of this fluid that the muscle becomes stiffened and hardened soon after death occurs. After a time, however, this coagulation liquefies and the muscle again becomes soft. This is the ordinary flexibility observed at about the time the body shows the first signs of decomposition.

There is a peculiar *sensibility* connected with muscle which is characteristic. While a muscle is in a state of spasm we perceive a peculiar sensation. When we lift a weight, or tread upon certain substances, or when we are pulling against a resisting force, the peculiar sensation produced belongs to the muscles and is called muscular *sensibility*. There is but little actual pain connected with destroying a muscle, but there is a sensation peculiar to muscle and distinct. A good illustration is that peculiar sensation of fatigue felt in the muscles, which we all have appreciated after carrying a weight for a long time. I have already told you that muscle possesses a property known as *irritability*, by means of which it contracts when under the influence of a stimulus. In order that this property may manifest itself certain conditions must be fulfilled, namely, the muscle must be anatomically and chemically intact. That is to say, as soon as an alteration takes place in the normal chemistry of the muscle, this irritability ceases, and the same is observed when its anatomical elements are destroyed. For example, if we plunge a muscle into hot water and coagulate certain substances, which in a normal condition are fluid, the muscle becomes changed chemi-

cally; and on the other hand, if we cut, or tear, or stretch a muscle beyond a certain point, we have injured it anatomically. In either instance the muscle ceases to respond to irritation.

A curious experiment has been performed by Brown-Séquard upon muscle after rigor mortis has commenced. [We know that during the time of rigor mortis it is impossible to obtain muscular contraction in response to the action of a stimulus.] Brown-Séquard injected into the arteries of a limb in this condition a certain quantity of fresh defibrinated blood. Of course this blood returned by the veins, and in this manner a new quantity of nutritive material was sent to the parts; and when this had been continued for a certain length of time, he found that contractions followed the application of an irritant. In other words, he found that after rigor mortis had been established, the simple injection of defibrinated blood caused *irritability* to return. It has been shown, furthermore, that when the abdominal aorta of the dog is ligated, in the course of a minute or two all voluntary movements cease, and the muscles refuse to respond to stimuli. But when the ligature is removed and the circulation allowed to become re-established, the muscles will be restored to their normal condition. The foregoing proves that the muscle must be supplied with a sufficient amount of nutriment in order to retain its irritability for any length of time.

I wish now to show you a series of very curious phenomena, namely, the *electrical currents* in muscles. These currents were discovered a number of years ago, and have been the subject of a large amount of experimentation. I will first explain the theory and then show you, as well as possible, the actual experiments. The adjustments for these experiments are exceedingly delicate and are really more fitted for the laboratory than the class-room.

Imagine a piece of muscle, with a longitudinal surface either natural or artificial, and a transverse surface, either natural or artificial; there are currents passing from the longitudinal to the transverse portions,—be the distance great the current will be more intense, and vice versa.* This depends, according to Du Bois-Reymond, upon the peculiar electrical condition of the molecules of the muscle. He supposes that a muscular fibre is made up of electrical molecules, called *peripolar molecules*, and that each molecule has an equatorial belt showing positive electricity; this positive belt is placed between two polar regions of negative electricity (as shown in figure).

Fig. 1.

In a transverse section the negative poles are bare, and consequently the current flows from the positive longitudinal to the transverse section.

This is what is called the reflecting galvanometer,† which is very sensitive.‡

For the purpose of experiment I use the gastrocnemius of the frog [preparation made], and place its

* Illustrated by diagram.

† The instrument used was a reflecting galvanometer on Sir W. Thomson's principle, of 5,000 Ohm's resistance. Instead of employing the ordinary coal oil lamp, the calcium light was substituted, thus enabling, by the projected reflection, all present in the lecture-room to follow the deviation on the scale.

‡ Diagram and description of instrument followed.

longitudinal surface on the cushion* of the galvanometer, its transversely cut surface I bring to the other cushion.

Now watch the spot of light [at zero on the scale]; as the transverse surface touches the second cushion you see the instant deflection shown by the moving spot of light. I place the muscle in the opposite position on the cushions, and you perceive the deflection is in the opposite direction.

Thus, gentlemen, you see there are electrical currents in muscle so long as it is in a living condition. Next, suppose I kill this muscle by immersing it in hot water, and then attempt to find these currents [experiment made]. They cannot be found, which demonstrates to us the fact that during *life only* these currents existed.

There are various other currents found in connection with the living body.

Should a piece of nerve be placed between the electrodes, or cushions, in the same manner as the muscle, we shall find that while the nerve is living it will give a variation which follows the same law as that which was observed in the muscle.

If the nerve be killed by dipping it in hot water, it loses its irritability, and the currents disappear. This nerve-current is modified, as we shall see further on, when certain constant electric currents are passed through the nerve.

At the preceding lecture I told you that when a muscle contracts a wave passes through it; if the muscle itself were stimulated, a wave passed that could be appreciated, and when the nerve which supplied the muscle was stimulated, a large number of waves were developed, and in this manner the contraction became very rapid.

Fig. 2.
MUSCLE STIMULATED.

I propose to show you this morning, if possible, the wave of muscular contraction following the stimulation of the muscle itself. Before making the experiment, we wish to eliminate all action of the nerve; for the purpose I introduce into the body of this frog a sufficient quantity of woorara to paralyze all the motor nerves of the animal. In this way we remove all nerve influence from the muscle, leaving the muscular irritability.

Fig. 3.
NERVE STIMULATED.

I now decapitate the animal [frog being completely paralyzed], amputate the leg, and separate the gastrocnemius muscle. I next attach a ligature to the tendo Achillis, to be used for stretching the muscle, separate the remaining muscle from the bone, leaving the gastrocnemius as free as possible, and place another ligature upon the bone, to be used also for the purpose of holding the muscle tense, and lay the preparation in this little trough.†

* Cushions are non-polarizable electrodes to prevent any extraneous currents from forming, which produce errors.

† The trough, made of hard rubber, has a post at one end, to which the bone is made fast; at the other end the ligature, attached to the tendo, passes over a pulley and is weighted to keep the muscle stretched. Two levers lie across the muscle, one near the tendo, the other near the

bone, the distance between being accurately measured. Both levers are in communication with writing levers, arranged so as to record exactly, one above the other, on the cylinder.

PHTHISIS PULMONALIS.

By FRANCIS DELAFIELD, M.D.,

LECTURES ON PATHOLOGICAL ANATOMY AT THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK CITY.

GENTLEMEN:—We will now pass to the study of those lesions in the lungs which are usually classed together under the names of pulmonary phthisis, tuberculosis, or consumption. You are doubtless aware that much difference of opinion exists as to the real nature of these lesions, and you may even have been discouraged by reading the different views expressed in your textbooks concerning them.

It is my wish to try to render the subject somewhat plainer to you, by stating as definitely as possible what the terms of the problem are which we are called upon to solve.

One of the first points which strikes us in our study of this question is that we have to deal with three distinct conditions—scrofula, tubercles, and inflammatory products. Let us, therefore, consider these three conditions separately, and then try to see how they are related to each other.

Of scrofula we see so little in this country that it is difficult for us to appreciate the prominent place it holds in the minds of physicians in European countries. It is a condition which is hardly susceptible of a definition, and yet it is not hard to understand what is meant by the term. It means this: When an individual acquires an inflammation of a mucous membrane, of the skin, of the joints, of the bones, of the genito-urinary apparatus, or of almost any part of the body, such an inflammation usually runs an acute course, and terminates in resolution, or in suppuration, or in the formation of organized new tissue. But if the inflammation, instead of doing this, simply reaches a certain point and stays there, and then, instead of resolving, or of suppurating, merely goes through a succession of degenerative changes, such an inflammation is said to be scrofulous. The scrofulous inflammations have several well-marked characteristics. They are very slow in their progress; they are very rebellious to treatment; they are accompanied by an extensive cellular infiltration of the inflamed parts, so that when the degenerative changes ensue there is large destruction of tissue. The degeneration which occurs in the products of such a scrofulous inflammation is peculiar in its nature; it is commonly called cheesy degeneration, and consists in the transformation of the products of inflammation into a dry, yellow mass composed of amorphous granular matter. Examples of this form of inflammation will at once occur to you. Caries of the vertebrae, hip-joint disease, white swelling of the knee-joint, scrofulous orchitis, and enlarged lymphatic glands are all of frequent occurrence. Of

bone, the distance between being accurately measured. Both levers are in communication with writing levers, arranged so as to record exactly, one above the other, on the cylinder.

* The irritation was accomplished by a single induction shock applied to the end of the muscle nearest the bone. As the various portions of the muscle became thickened during contraction, first one lever recorded and then the other; thus producing curves as in Fig. 2. Had all parts of the muscle contracted at the same instant both tracings would have been made at the same instant, Fig. 3. The cylinder was revolving once in one second. Circumference of cylinder 42 centimetres. By means of a recording tuning-fork the exact time can be most easily obtained. In Fig. 2 the vibrations of the fork are recorded just under the lever tracings.

the scrofulous inflammations of the skin and mucous membranes we see but little in New York.

You will see at once that such inflammations as these, running this peculiar course, can be explained in two ways. We may say that a certain number of individuals are born with, or acquire the scrofulous diathesis—that they are scrofulous persons—and when any part of their bodies becomes inflamed, that in consequence of this scrofulous diathesis, the inflammation takes on the scrofulous character. Or we may hold that, just as we find croupous, or catarrhal, or suppurative inflammation occurring in different individuals, or in the same individuals at different times, so we may find the scrofulous inflammation; and that it is no more necessary to suppose a scrofulous diathesis than a suppurative, or a catarrhal, or a croupous diathesis.

Our views on this subject can hardly fail to be influenced by our surroundings. In Germany or in France we see great numbers of persons, especially children, who at once strike us by their unhealthy appearance. We see that every inflammatory process set up in them takes on the scrofulous character. We see their faces scarred with scrofulous sores, their glands swollen, their bones destroyed, and it seems natural to class them all together as the victims of some constitutional disease.

In this country, however, our experience is somewhat different. We see, indeed, a certain number of such unhealthy persons, but we also see the same scrofulous inflammations occurring in persons otherwise healthy. We see caries of the spine produced by injuries in healthy adults; we see healthy children attacked by hip-joint disease, recover from it, and go through a long life in perfect health; we see lymphatic glands pass through all the stages of scrofulous inflammation and degeneration without any permanent effect on the health of the patient. So here it is not unnatural for us to think it possible that this form of inflammation is merely one of the natural varieties of that process.

Two other questions concerning scrofulous inflammation are still to be considered: 1st. Are tubercles present in scrofulous inflammation? 2d. Does the cheesy degeneration which accompanies scrofulous inflammation give rise to tubercle.

1st. Are tubercles present in all scrofulous inflammations? We find this question answered in four ways. Some hold that a scrofulous inflammation is really nothing but the infiltration of the affected part with tubercles. Some hold that there is first a formation of miliary tubercles, and that these become cheesy and are accompanied by inflammatory changes. Some hold that the process is simply an inflammation, succeeded by degeneration, and that no tubercles are present. Some hold that the process is an inflammatory one of a peculiar nature, resulting in the formation of a cellular tissue of low vitality, and that this process is identical in its nature with tuberculosis. It is easier to point out the defects in these different theories than it is to construct a better one. Probably the entire truth in this matter has not yet been reached.

2d. Does the cheesy degeneration which accompanies scrofulous inflammation give rise to tubercle? This is a question which is now very generally answered in the affirmative—perhaps too hastily. This opinion has been formed in great measure from the results of experiments made on animals. We must therefore consider here the artificial inoculation of tubercle. Attempts to inoculate tubercle artificially were made at quite an early period.

TUBERCLES—INOCULATION.

History.—Kortum, 1789, Paris, rubbed fluid matter from a scrofulous ulcer into the neck of one boy, and inoculated another boy with the same matter, in the same place, but without results.

Hebréard, 1802, inoculated three dogs with matter from scrofulous ulcers, but without results.

Salmae, 1805, inoculated a number of animals with scrofulous matter, but without results.

Lepelletier, 1810, inoculated four guinea-pigs, but without results.

Cruveilhier, 1826, injected mercury into the trachea, arteries, and veins of animals, and produced multiple abscesses, which he called tubercles.

Villemin, 1865, read his first memoir, giving his experiments with gray tubercles on rabbits, and concluding that tuberculosis is a specific affection, like syphilis, that it has its cause in an inoculable material, and that it can be easily inoculated on rabbits.

In 1866 he published his second memoir, and in 1868 his book on the same subject. He inoculated rabbits from men, from cows, and from other rabbits; also guinea-pigs, dogs, cats, and sheep. In dogs and cats he obtained no well-marked results, in sheep no result. The matter which he used was gray tubercles from the lungs and serous membranes; the cheesy infiltrated matter from lungs, and the cheesy glands, sputa and blood of phthisical patients. With all these matters he obtained positive results. In the lungs, liver, spleen, and serous membranes of the animals inoculated he found numbers of small gray tumors, identical in appearance with the gray miliary tubercles of men.

In four cases he produced yellow, infiltrated, partly softened, cheesy lobules in the lungs, and in one case a cavity.

From these experiments he deduced the conclusion that tuberculosis is a specific, inoculable disease, like syphilis; that gray and yellow, isolated and infiltrated, are all of the same nature; that they have no specific anatomical elements, but that the proof of their nature is their inoculability.

Lebert, 1866, repeated Villemin's experiments on rabbits and guinea-pigs, and confirmed his conclusions. After this he went on to inoculate with miliary tubercles, cheesy infiltrated tubercles, cheesy lymphatic glands, portions of cancer, mercury and charcoal. From these experiments he concluded just the opposite. That tubercles are not specific nor inoculable. That they are simply the result of circumscribed inflammations; that they have no specific elements. In one case, in a guinea-pig, inoculation of peritoneal granulations gave rise to cavities in the lungs.

Harard, 1867, inoculated four rabbits, two with gray granulations and two with cheesy infiltration. The first two succeeded, the second two did not, from which he concluded that gray tubercles and cheesy infiltration were different.

Colin, 1867–1868, one of the commission appointed by the Paris Academy, made two reports embracing experiments on forty-six animals, rabbits, guinea-pigs, dogs and sheep. He deduced the following conclusions:

1. Inoculation of gray and yellow tubercular matter produces tubercles.

2. It is most probable that the tumors produced by inoculation are partly due to the material inoculated, and partly to the suppuration produced around the inoculated material.

3. The extent of the lesions produced is in proportion to the quantity of material inoculated.

4. It is the tubercular material itself, and not any virus, which is taken up by the lymphatics and deposited in the different organs.

5. The deposits in the lungs, when they are firm, shining and semi-transparent, are certainly tubercular; when they are opaque and yellow, their nature is not so certain.

Behier, Pidoux, Vulpian, and Empis inoculated with various results.

Clark, of London, 1867, produced gray tubercles in rabbits by inoculation with gray tubercles, and in two cases with non-tubercular matter.

Saunderson, 1868, produced gray tubercles in guinea-pigs, by inoculation with gray tubercles, pus, non-tubercular products, and by causing chronic supuration with setons.

Wilson Fox, 1868, inoculated 117 guinea-pigs, and 12 rabbits.

He inoculated gray tubercles; red, gray and cheesy hepatization, pus, sloughs from wounds, waxy liver, putrid muscle, and used setons. He produced miliary tubercles in the lungs, bronchial glands, spleen, liver, omentum, and intestines. These tubercles were identical microscopically with those in man. Of 117 pigs 58 became tubercular and 6 doubtful.

Verga, Biffi and Mantegazza, 1868, in Italy, inoculated rabbits with the same results.

Waldenburgh, 1869, Berlin, inoculated seventy-one rabbits and twenty-eight guinea-pigs. He inoculated gray tubercles, cheesy glands extirpated during life, cheesy pus, gray tubercles, and cheesy glands preserved in alcohol, and catarrhal pharyngeal sputum treated with permanganate of potash. He also injected gray tubercles and inflamed glands rubbed up with aniline blue, and found the aniline in the miliary tubercles produced, in the white blood-globules and in some of the tissues.

He also inoculated a goat nine times with fresh matter and tissues preserved in alcohol. The animal's health was not affected, but tubercles were produced.

Most of the animals died of the disease. The tubercles produced were true gray miliary tubercles. They were found in the lungs, intestines, omentum, liver, spleen, kidneys, lymphatic glands.

Out of 100 animals thirty-four became tuberculous. He inferred that the tubercles were produced by the absorption of the fine particles of the inoculated matter, the circulation of these in the blood, their deposit in the different tissues, and their presence causing irritation and new growth.

Klebs injected tubercular matter into the abdominal cavity, and produced tubercles of the peritoneum and other organs. He regards the tubercles as formed in and propagated by the lymphatics.

Cohnheim and Frankel (1868) inoculated by introducing into the abdominal cavities of rabbits and guinea-pigs portions of tubercle, of fresh and putrid tissues of all varieties, also pieces of India-rubber, of paper, of lint, etc. The result of these procedures was always peritonitis. In many cases this killed the animals, in others the foreign body became encapsuled and was found surrounded by cheesy pus. In these cases miliary tubercles were found throughout the body. Cohnheim inferred that cheesy pus was the excitant of tubercle, and in proof of this he found that such cheesy pus, mixed with a solution of salt, filtered and injected into the blood-vessels, produced tubercles in dogs.

All these experiments, therefore, which seemed at first to demonstrate that tubercles could be inoculated like small-pox, resulted in this conclusion. In certain animals—guinea-pigs, rabbits and dogs—if we excite

inflammation by introducing under the skin or into the peritoneum any foreign substance, the inflammation thus produced will often assume the serofulous character. If it does so, there is usually a collection of cheesy matter at the point where the inflammation was excited; near this the lymphatic glands will be enlarged, and in the lungs and other viscera we will find miliary tubercles. It seems to be a natural conclusion from this, that serofulous inflammation with cheesy degeneration produces foci of cheesy matter; this cheesy matter is absorbed, infects the entire body, and thus produces miliary tubercles.

This doctrine was very soon applied to the tuberculosis of man. It is now very generally believed that in many cases miliary tubercles are the result of auto-inoculation from a cheesy focus. Thus Niemeyer says that patients with chronic cheesy pneumonia are always in danger of infecting themselves and becoming tuberculous. Rindfleisch says that tuberculosis in individuals who are not serofulous is a thing unknown. Hæter lays down the rule that if we find a cheesy lymphatic gland in any part of the body, we must extirpate it at once to prevent tubercular infection.

You will find, however, that in this country there are some difficulties in the application of this doctrine. These difficulties seem to depend on the fact already mentioned that here serofulous inflammations are less frequent and less extensive. It is impossible to ignore the fact that we meet with cases of general tuberculosis without cheesy foci; and that we meet with extensive cheesy deposits without tubercles. So that we may be permitted to doubt whether the law of the production of tubercles from self-inoculation with cheesy products is as absolute a one as has been stated.

II. Our next step must be to inquire what products of chronic inflammation do we meet with in the lungs? These products are all comprised under two heads—products of inflammation within the air cells and bronchi, and products of inflammation between and outside of the air cells and bronchi. We have already seen in studying pneumonia that there is a form of inflammation in which the air cells are filled with fibrine and large, nucleated cells of epithelial character, while the bronchi are filled with pus cells. This is one of the forms of pneumonia which we meet with in phthisis. We have also seen that there is another variety of inflammation affecting the interstitial connective tissue of the lungs, and called interstitial pneumonia. All the inflammatory products found in phthisis are due to the existence of one or both of these varieties of pneumonia.

What lesions do we find then in the lungs which are undoubtedly the results of inflammation? The intra-alveolar pneumonia fills the air cells with fibrine and epithelium, and the bronchi with fibrine and pus. Wherever this takes place the lung becomes solid—hepatized. This hepatization is at first sometimes red, sometimes of a gelatinous, gray color. The absence of a first stage of red hepatization in some cases is due to the fact that the inflammation is from the commencement a chronic one, that it has no acute stage in which the blood-vessels are congested and the blood escapes. The products of inflammation thus formed frequently degenerate, then the hepatized lobules are of a more opaque gray color, or whiter, or yellow and cheesy. They may remain cheesy for an indefinite period, or they may calcify, or the walls of the air vesicles may be so compressed that they lose their vitality, become necrotic, soften, break down and form cavities. The same degenerative changes take place in the pus and fibrine which fill the small bronchi.

The extra-alveolar or interstitial pneumonia results in the production of new fibrous tissue. This new tissue is sometimes dense and hard, composed of fibrillated connective tissue with few cells, sometimes is softer and looser, sometimes is composed of reticulated connective tissue. It resembles closely the new fibrous tissue which is produced in other parts of the body by chronic inflammation. This new tissue is found thickening the pulmonary pleura, surrounding the bronchi and blood-vessels, traversing the lung in broad bands, mottling it with large patches or with minute nodules. It is either white, gray, or black in color.

When in the same lung both the intra-alveolar and the extra-alveolar forms of pneumonia continue as a chronic disease for years, the inflammatory products which result modify each other and give rise to a great variety of lesions. It is these complicated lesions which it is so difficult to distinguish from tubercles.

Original Communications.

COMMUNUTED FRACTURE OF FEMUR IN A PATIENT ÆT. 83 YEARS; PLASTER-OF-PARIS DRESSING; RECOVERY.

By R. W. GIBBES, M.D.,

OF COLUMBIA, S.C.

MR. J. H. W. (ætat 83, 5 feet 7 inches high, weight about 165 pounds, of remarkable physique and activity, then the regular mail-carrier between the different railroad depots and the Columbia post-office, a soldier in the war of 1812) fell over his piazza railing (about 18 feet) on the night of January 2, 1873; thought he struck on his right hip; he managed to raise himself up, and was discovered standing and holding to a firm post which happened to be just at hand.

I found him a few minutes after (9½ p.m.) in bed, with right foot everted and a considerable shortening of the limb, and had no difficulty in detecting an oblique fracture below the trochanters. I readily reduced it, and left him with an opiate. After a necessary delay of about fifteen hours, with the efficient aid of my friend Dr. B. W. Taylor, and several of the younger members of the profession, the plaster-of-Paris dressing was satisfactorily applied, after the well-known method in vogue for several years past in Bellevue Hospital; my venerable patient being kept for some time suspended above the table and fully under chloroform, etc., etc.

On the 6th we had him on crutches, and assisted him in making a few steps, but as he had no desire to try himself again, it was not until January 21 that he began to walk around his room daily. On February 14th (forty-three days after the accident) the apparatus was removed, and a simple roller applied for a few days.

Firm union took place with apparently a very moderate amount of provisional callus, and he soon walked well with his crutches up and down stairs, being disposed to abandon them even when in the house.

After three or four months, careful and accurate measurements of the limb were taken, and the shortening found to be just three-fourths of an inch.

On the 29th of June following Mr. W. died of apoplexy, and I was kindly permitted to remove and preserve the bone.

The specimen presents, as far as I know, a unique

form of fracture. It shows almost the ordinary simple oblique fracture immediately below the trochanters, complicated—or rather, as I think we may say, *relieved*—by another line of fracture, by which the lesser trochanter and a fragment of the posterior portion of the shaft are separated, thus making three distinct pieces. The separation of the middle fragment with the trochanter minor is to be regarded as a happy circumstance, as it no doubt conduced to the good results of the treatment, by at least preventing angular deformity. The inferior line of fracture commences at the lowest point of the anterior inter-trochanteric line, and extends obliquely, downwards and outwards, to a point immediately external to the *linea aspera*, and four inches below the lesser trochanter. This separated the shaft from the neck and trochanters. The superior line begins from the inferior line, at a point about three-fourths of an inch from and on a level with the trochanter minor; arching upwards, it passes over that prominence, crosses the posterior inter-trochanteric line at right angles, and then descends outwardly nearly parallel with the inferior line. This separated the trochanter minor, along with a wedge-shaped portion of the shaft, as is seen in Fig. 1, exhibiting the

specimen from behind. The three fragments, A, B, and C, brought under the influence of the muscles and the weight of the limb, were considerably displaced. The middle one (B) was drawn inward superiorly by the *psaos*, while its sharp inferior extremity was removed about half an inch out from the shaft by the action probably of the *gluteus maximus*, since on this fragment is located the whole of the "gluteal ridge;" thus the small trochanter is made to assume a position three-fourths of an inch nearer the head of the bone than it occupies in the normal state, whilst happily the middle and inferior fragments are held closely applied to each other, except at their extremities. By the action of the *gluteus medius* and *minimus*, as well as of the *pyriformis*, *gemelli*, and *obturator*s, the superior fragment was made to undergo a change in position, not unlike that induced in the middle one, its inferior point being tilted outwards, while the head is drawn in and the wedge-shaped middle fragment is held tightly between the other two, the shaft or lower one being pulled up until it struck the arch and could shorten no more.

At all points where the fragments were in contact, firm bony union has occurred, and, indeed, it is very difficult to trace the superior line of fracture where it arches around the trochanter minor. From the posterior edge and external point of the upper fragment

there are growths (*d, d*) of new bone—the first one reaching and becoming firmly attached to the middle fragment only—another below and more extensive, binding together strongly all three fragments.

The cancellous structure of the bone is much expanded, the cells being very large, and they contained an abundance of fat.

NOTE.—Prof. F. H. Hamilton, to whom the case was sent, has written us the following note bearing upon the same:

“DR. SHRADY—My dear Sir: I have sent you the above very interesting case, by request of Dr. Gibbes; who has asked me, also, to add any comments I may see fit to make.

“In addition to the fact that the accident, as described and as illustrated in the specimen now before me, is quite unique, and in addition to the other points of interest noticed by Dr. Gibbes, I wish to call attention to one more very practical point, namely, that the apparatus, although it performed all, perhaps, that any other apparatus could have performed, yet it did not prevent shortening—that, in truth, the femur shortened until it was arrested by the contact of the upper end of the lower fragment with the neck.

“My impression is, that it is shortened much more than three-quarters of an inch, but this is not material; within that limit the apparatus was unable to prevent shortening. FRANK H. HAMILTON.”

Progress of Medical Science.

HEMP COMBINED WITH PLASTER-OF-PARIS FOR SPLINTS.—Dr. Beely reports from the clinic of Prof. Schönborn, of Königsberg, that for about a year they have been using a combination of hemp with plaster-of-Paris in place of any similar apparatus, and he recommends it very highly both for its cheapness and various other good qualities. They have now tried it in about fifty cases, comprising the following injuries or operations: simple and compound fractures, affections of the joints, wounds of tendons, in deep wounds of the soft parts of the extremities, resections, in rachitic curvatures and in club-foot. The materials employed are the ordinary plaster-of-Paris used by surgeons, and hackled hemp, the fibres of which must lie as parallel as possible. The hemp is made into little loose bundles about an inch to an inch and a half wide, a third of an inch thick, and fifteen to twenty inches long. Four or five such bundles suffice to make a dorsal splint for the leg and foot of an adult. Having oiled the skin the bundles of hemp are dipped into the thin paste of plaster and water, the excess squeezed out by drawing them between the fingers and then laid directly upon the skin so as to be parallel with the axis of the limb and slightly overlap each other until the required size and thickness has been obtained, and it should be from a third to a half an inch. Reinforcements can be added where needed, and these will adhere firmly even if applied several days after the original apparatus. Additional plaster may be rubbed on to give a smooth and finished appearance. The apparatus becomes firm after five or ten minutes, and may be rendered waterproof after drying by applying an alcoholic solution of shellac. If desired, a flannel bandage may be carried around outside of the plaster apparatus and so incorporated with it. The limb so incased may be suspended by incorporating into the splint some little wire loops or eyes, in the ordinary way. Dr. Beely

poses at some future time to give more details of cases treated in this way. Among other recommendations of the method are the cheapness of the material, the readiness with which it adapts itself to the form of the body, its porosity, the durability of the splint so made, and the facility of its application.—*Berl. Klin. Woch.*, April 5, 1875.

THE BLOOD AND SPLEEN IN PYÆMIA.—Birch-Hirschfeld has found the average weight of the spleen to be about twice as great in cases of pyæmia with large metastases as in those phlegmonous cases in connection with surgical injuries which ended fatally without considerable deposits in remote organs. In the latter its weight was but little above the normal. He therefore regards the swelling of the spleen in pyæmia as a reaction of the organ against the infectious material in the blood. Examining the blood in such cases, he is now inclined to believe that formerly he over-estimated the number of free organisms present; for after taking the blood, with suitable precautions, from a recent corpse, he finds that free bacteria are not constantly present, and their actual number is small. He believes, however, that the fine granulation of the white blood-corpuscles in pyæmia is partly due to sphero-bacteria. In such cells chains of three or four links are often seen, and they differ from fat in optical characters, while they also remain connected together when the white blood-corpuscles are destroyed. The degree of this granulation varies exceedingly, sometimes involving all the white blood-corpuscles, and these latter are often found in as high proportion as 5 to 100. These intra-cellular spherobacteria, he believes, are also found in the pus cells of puerperal peritonitis, as mentioned by Waldeyer. Though maintaining the opinion that spherobacteria are found in the blood of pyæmia, he is not willing to declare them to have a causal connection with the disease. It is suggested that the histological changes of the cells of the substance of the spleen are completely analogous to those of the white blood-corpuscles.—*Report of the Session of the Versammlung Deutscher Naturforscher und Aerzte zu Breslau in Allg. Med. Cent. Zeit.*, April 7, 1875.

INGRAFTING OF TENDONS.—M. Tillaux has practised this operation in a patient who had laceration of the extensor tendons of the ring and little fingers. The operations were done a month after the accident and when cicatrization was complete. The digital extremities were easily found, but not so the superior extremities. Accordingly the operator incised the tendon of the common extensor, and refreshing the superior ends of the broken tendons of the ring and little fingers, slid them into the place prepared for them, thus grafting them in. The operation was successful, and the patient recovered the use of his fingers.—*Journ. de Med. et de Chir.*, March, 1875.

ADULTERATION OF HOPS.—A number of samples of beer and porter were examined at the chemical laboratory of the Upsala University, and in addition to the lupuline, such foreign substances as absynthine, quassine, and menyanthine were found. The brewers from whom the specimens were obtained denied having used any bitter substance but hops. A number of specimens of hops, coming from Germany, were then examined by Dr. Almén, and it was found that some of them contained tincture of absinthe, etc. It is probable that hops which have become old, damaged, or otherwise unsalable, are freshened up by the addition of the tincture, and thus the brewer unconsciously prepares adulterated beer and malt extracts.—*Upsala Läkareförs. Förhandl.*, X., 5.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, May 15, 1875.

THE MEETING AT LOUISVILLE.

AGAIN we have occasion to witness the wisdom of the change in the plan of organization of the American Medical Association in regard to the settlement of purely ethical questions. The meeting just held in Louisville is the second one since the Judicial Council has had an existence, and already we begin to see the Association taking a stride towards respectability and usefulness, which it has not done for many years past.

The new arrangement of the Sections is another item which must not be lost sight of in the estimation of the benefits of the Association, not only to its individual members, but to the profession at large. The appointment of representative men as presiding officers of these bodies has been attended with the best of results in securing first-class contributions to the transactions and in stimulating interesting and profitable discussions. On the whole, the meeting was a success. Very many questions of great importance were brought up, and very prudently disposed of. A reference to our report in another place will give our readers a better idea of the extent and character of these topics than any general remarks which we may offer upon them.

The nomination of officers under the new plan of selection of State delegates was attended with less of that caucusing and wire-pulling which have characterized the working of the committee heretofore. There is no doubt that the selection of members of the Nominating Committee by the different State Societies is calculated to correct a great abuse on the part of certain delegates, who always managed to get the most influential positions when they were farthest away from those who knew them. Under the present arrangement, however, those who have the best reputations at home have the best opportunities for exercising their influences in the central body. The system deserves a more extended trial. We say extended,

because some of the States, either not being aware of the regulation regarding the election of the members of the Nominating Committee, or not caring to be too particular to place the best man at the head of the list, did not fairly represent their influences.

The attendance on the meeting was quite large, but as is generally the case the delegates were largely recruited from the more immediate vicinity of the place of meeting. It is impossible to expect it otherwise. While there are always a few who will be present at every meeting the great majority of members are entire strangers. We have already alluded to the disadvantage of this state of affairs to the general welfare of the Association, more especially in regard to medical legislation. But even this is in a measure removed by the appointment of the Judicial Council, to whom all matters bearing upon medical politics are referred.

A HOMŒOPATHIC MEDICAL DEPARTMENT AT ANN ARBOR, MICH.

THE Legislature of Michigan have just passed the following bill, authorizing the regents of the University to establish a homœopathic medical college as a department of the State University, and appropriating \$6,000 per annum for its support:

SECTION I.—The people of the State of Michigan enact: The Board of Regents of the University of Michigan are hereby authorized to establish a homœopathic medical college as a branch or department of said University, which shall be located at Ann Arbor.

SECTION II.—The Treasurer of the State of Michigan shall, on the first day of January, 1876, pay out of the general fund, to the order of the Treasurer of the Board of Regents, the sum of six thousand dollars, and the same amount on the first day of January of each year thereafter, which moneys shall be used by said regents exclusively for the benefit of said department.

It is entirely premature to say what will be the action of the now-existing medical department, but it will be seen that the homœopathic school is to be a separate college. The regents have not met since the passage of the bill, so that we cannot even say whether they will accept the grant. Twice previously they have refused to obey the legislature in this matter, but on both those occasions the homœopathic department was made a branch of the existing medical school, thus mixing those two systems of teaching and practice. As this objectionable feature is removed in the present bill, we can surmise that the regents will now accept the grant, and establish a new college.

The present medical department is almost self-sustaining, the expenses over and above students' fees being about \$1,200 to \$1,500 per annum.

MEDICAL SOCIETY OF NEW JERSEY.

THE Medical Society of the State of New Jersey will shortly hold its one hundred and ninth annual meeting. It is needless to say that the attendance will be good. This is always the case. One of the oldest

Societies of its kind in this country, it commands an influence over the profession of its State second to none of the kind anywhere. The meetings are always interesting, and we doubt not that the forthcoming one will be a model of its sort. By reference to the arrangements for the next meeting, which we publish in another column, it will be seen that every effort is made by the committee to make the meeting worthy the expectations of the most sanguine. We shall endeavor to find room for an abstract report of the proceedings of the association in a future number.

THE NEW BUILDING FOR THE NEW YORK ACADEMY OF MEDICINE.

The next stated meeting of the Academy will be held in its newly acquired hall, 12 West Thirty-first Street, on Thursday evening, May 20, 1875, at eight o'clock precisely, when the Committee on Ways and Means will pass the property to the custody of the Trustees, and present the results of their labor thus far in carrying into effect some of the original intentions of the organization. It is confidently expected that the exercises on that evening will be conducive to the good of the profession. That this building will prove sufficient for temporary purposes only is quite certain; for in this great city the wants of the medical profession increase with its numerical growth, and the time must soon come when more commodious quarters will be required even by the Academy.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

TWENTY-SIXTH ANNUAL MEETING, HELD AT LOUISVILLE, KY., MAY 4, 5, 6, AND 7.

TUESDAY, MAY 4—FIRST DAY.

The Association was called to order by Dr. E. Richardson, the Chairman of the Committee of Arrangements, after which prayer was offered by the Rev. Dr. Lamar. Dr. Tener, of Washington, D. C., then introduced Dr. W. K. Bowling, of Nashville, Tenn., the President elect, who called for the report of the Committee of Arrangements. The Chairman of the Committee of Arrangements, after welcoming the members in an appropriate address, made a detailed report of the plan for the general meetings of the Association and of the different Sections, the former occupying the morning session from 9.30 to 1 P. M., the latter the afternoon session, commencing at 3 o'clock. Dr. N. S. Davis, of Chicago, announced the presence of Dr. Botsford, the President of the Canadian Medical Association, and moved that he be invited to take a seat on the platform. Dr. BOTSFORD made a few remarks in response to the compliment, after which

THE PRESIDENT'S ANNUAL ADDRESS.

The PRESIDENT, DR. W. K. BOWLING, delivered his annual address. After sketching the history of the Association from its foundation to the present, and noting the radical changes which have from time to time been effected in its plan of organization, he remarked that it was now in a condition to exercise its

influence in the direction of shaping the educational interests of the profession.

"Let it be solemnly resolved by this meeting," said he, "that it shall be regarded as derogatory to the character of any physician, in any part of the United States, to take under his care as a student of medicine any one who cannot exhibit evidence of having taken a degree in a regularly chartered college, or a certificate of qualifications necessary to become a student of medicine, from a board of examiners appointed for that purpose by the American Medical Association. This will do the work.

Territories and new States, in a country like ours, in a formative state, will provide themselves with medical helps in the mode we have described, which, existing outside of this body, and independent of it, will occasion it no concern whatever. Nor would the schools suffer pecuniary loss under this rule. When it was generally known, as it would soon be, young men desiring to enter the profession would earnestly devote themselves to the duties of preparation, nor relax their efforts till possessed of the degree or the certificate.

Again, many educated young men, under this rule, would turn their attention to medicine, whose votaries were to consist of their peers, who, under the existing rule, would not risk its levelling influences. Let the doctorate imply something more than "two full courses of lectures, the last of which in this institution." Besides, it would give the college an ample excuse for not receiving every uneducated, lazy dolt who desired to make a living under false pretences.

There is nothing really binding in the rule suggested. The only power in the matter is the great moral weight of the Association. It enacts nothing, but simply asserts what every member of it knows to be right. After a few years such a certificate of the Examining Board, or evidence of a college degree, might be declared necessary in order to enable an applicant for membership in this body to secure admission; for surely it is the common privilege of all organizations to judge of the qualifications of their own members; then will the certificate of membership here pass the holder anywhere as a gentleman and scholar.

It is precisely in this way that the medical department of the army and navy are purified. The adoption of this addition to the code of ethics would furnish medical gentlemen an excuse for getting rid of applicants for office study whose preliminary education they know to be defective, and whose relations they would dislike to offend by saying so.

Referring to the general progress of medicine during the past century, he said:

During the past year, a "scientist," whatever that means, having the supervision of a department of a widely-circulated political newspaper, published therein that the medical profession had not advanced a step in seventy years; and this cry, from many quarters, so prolonged and persisting, has established a popular belief. "To enlighten and direct public opinion," it is proper to state that a member of this body, our late lamented lexicographer, among the chiefs of learning and industry in his generation, and alike an ornament to his profession and to human nature, "to meet," as he writes, "the progress of medical science," in the sixth and seventh editions of his dictionary, added nine thousand terms and subjects, and in the eighth edition, twenty years ago, the same progress required four thousand more terms and subjects, and the edition of 1865, to the same end, required sixty-five pages

of new terms and subjects. That a profession, stationary, or in an active retrograde movement from some fancied height, should require all these new terms and subjects during its decline, is simply ridiculous, and those among us who believe this, and who have aided in fixing this belief upon the public, have, for the time, but yielded to the flattering and seductive influences of a generous imagination.

Old politicians, being crowded out, very naturally conclude, that the new ones are but imitating Phaeton's drive to destruction, and that the country, under their guidance, must inevitably go to pieces. Old men always have their lines cast in degenerate times, and the only consolation remaining to them is the reflection that their degenerate days will be the grand old time of patriotism, honor, and manhood of their descendants. One need no better authority than all the editions of Dunglison's Dictionary to assure him that, during this century, particularly, the progress of medicine, in all the countries of civilization, has been onward—right on—receiving not the slightest check from internal commotions nor outward pressure, but, like the tread of a mammoth, literally crushing out whatever accident or design placed upon its pathway.

That our own country has, during this period, contributed as much to this development as any other, no unprejudiced observer will dispute. During the last generation, especially, it has figured conspicuously on the frontier of medical progress; and that this Association has accelerated the movement is equally beyond controversy. As the iron-shod steed, speeding along the night-shrouded turnpike, illumines his way by the fire his own progress strikes from the resisting rocks, so this body, in doubt and darkness, often, when scorners smited and good friends hesitated, caught fire from the very friction of oppsing circumstances, and emerged, self-glorified, on its march to triumph.

At the conclusion a vote of thanks was passed, and the address was referred to the Committee on Publication.

On motion, Dr. S. D. Gross, of Philadelphia, was granted a portion of the morning session of Wednesday for the delivery of an address on "Venesection as a lost art."

After the transaction of some miscellaneous business, the Association adjourned until Wednesday, May 5th, at 9.30 A. M.

WEDNESDAY, MAY 5—SECOND DAY.

The Association was called to order by the President, after which the following delegates were proposed for permanent membership: Drs. C. J. Walton, of Mansfield, Ky.; W. S. O'Neal, Berlin, Ky.; E. D. Force and S. H. Horner, of Louisville; W. C. Hall, Franklin, Ind.; R. D. Huley, Elizabethtown, Ky.; C. J. Renfro, Pleasureville, Ky.; and W. C. Tucker, Danville, Ky.

The announcement of additional delegates was then made, and also the following members by initiation: Drs. W. B. Rodman, of Frankfort, Ky., and E. Poynter, of Midway, Ky.; J. H. Rock, of Chicago, and Drs. R. Bolling and S. O. Wetherbee.

NOMINATING COMMITTEE.

After a recess of fifteen minutes the following Nominating Committee was reported: Alabama, W. O. Baldwin; Arkansas, D. A. Linthicum; Connecticut, L. Williams; Colorado, C. Denison; District of Columbia, J. Eliot; Florida, E. T. Sabal; Georgia, T. J. Curtsy; Illinois, H. A. Johnson; Indiana, W. Lomax; Iowa, J. Williamson; Kentucky, Joseph W. Thompson; Maryland, J. Morris; Massachusetts, Na-

than Allen; Michigan, J. H. Beach; Maine, S. H. Weeks; Minnesota, E. C. Cross; Missouri, T. Kinard; Mississippi, B. F. Whitehead; New York, J. R. Wood; New Jersey, T. B. Flavier; North Carolina, N. J. Rittman; Ohio, W. W. Dawson; Pennsylvania, E. A. Wood; Rhode Island; South Carolina; Texas, E. T. Easy; Tennessee, T. A. Atkinson; Virginia, J. E. Chancellor; Wisconsin, E. P. Russell; West Virginia, John C. Happ; United States Army, J. R. Smith; United States Navy, Jas. Wilson.

AN APPEAL FROM THE CANADIAN MEDICAL ASSOCIATION.

The following communication from the Canada Medical Association was read and received:

MONTREAL, April 19, 1875.

W. B. Atkinson, Esq., M.D., Secretary American Medical Association:

DEAR SIR—As the time is approaching for the meeting of the American Medical Association, I have much pleasure in forwarding a copy of a resolution unanimously adopted at the last meeting of the Canada Medical Association, held at Niagara Falls on the 5th and 6th of August, 1874, and request that you will kindly bring it to the notice of your Association. The Canada Medical Association will meet this year at Halifax, Nova Scotia, on the first Wednesday in August, and would be much pleased at seeing, as heretofore, delegates from your Association, and I think it more than probable that our Association will be represented at your meeting by at least two of our members, one of whom will be our president, Dr. LeB. Botsford, of St. Johns, New Brunswick.

I am, dear sir, yours very truly,

A. H. DAUD, M.D., D.C.,

General Secretary Canadian Medical Association.

The resolution referred to in the foregoing letter was as follows:

"It was moved by Dr. Grant and seconded by Dr. Caniff:

"That, in consideration of the best interests of medical science, it is desirable that a medical conference should take place between the American and Canada Medical Associations, at some central point to be determined upon, and that the American Medical Association be advised as to the desirability of thus becoming more intimately acquainted, and affording an opportunity for the discussion of medical and surgical subjects on a common basis.

"The motion was carried unanimously, when Dr. Kingston, seconded by Dr. Botsford, moved:

"That in the event of such conference being determined upon, it would be desirable that the secretary of the Canada Medical Association notify the various local medical societies, so that our Dominion might take part in a manner worthy of the occasion and in keeping with the interests of medical science."

AN INTERNATIONAL CONFERENCE.

The following communication from Dr. E. Seguin, of New York, urging this Association to send delegates to Europe to confer with foreign medical associations in regard to the uniformization of clinical observations, instruments, scales, etc., was received and placed on file:—

To the American Medical Association:

MR. PRESIDENT AND GENTLEMEN—You have twice sent delegates to the British Medical Association, and kindred European societies, to invite them to consent to a plan of uniformity of methods, instruments, scales, and records of clinical observation. The proposition

has become more opportune since the meeting in Paris of the convention for the adoption of uniform weights and measures by all nations, in which convention Professors Henry and Hilyard represent the United States, but in which the special wants of unity of measures of our profession are not represented. This proposition was approved by Sir Wm. Jenner, MM. Reynolds, Gibson, Stewart, Squire, Sydney, Ringer, Wilson, and Tilbury Fox in England; on the continent by MM. Marey, Charcot, Lorain, Potain, Lepine, Ollier, and Chaveau—all ready to open a commission in Paris and a subcommission in Lyons, in order to concert in your plan of uniform observation. This plan embraces the unity of clinical thermometers, and of thermometric scales, charts, etc.; a uniform graduation of the sphygmograph, myograph, sphyrograph, æsthesiometer, dynamometer, globulimeter, ophthalmoscope, and other instruments of precision used in diagnosis, a uniform method of measuring and registering the hearing, and velocity of other sensory impressions, the regularity of co-ordinate movements, as the walk, and a uniform registration of all clinical cases according to their kind. Of this plan the International Medical Congress, meeting at Brussels, the 19th of September, proposes to carry out only one part, the uniform measurement and record of hearing by all nations. It is, therefore, important that the American Medical Association be represented this year at Brussels, in order to represent there the original plan of uniformization of clinical observations in its integrity and entirety.

Therefore the American Medical Association resolves to nominate new delegates, commissioned to again advocate in Europe the unity of clinical observations, and charges them to report progress in brief at the meeting in 1876.

E. SEGUIN.

VENESESECTION ONE OF THE LOST ARTS.

Dr. S. D. Gross, of Philadelphia, read an elaborate paper with the above caption, the tenor of which was to prove that extremes are dangerous, and that the time was not far distant when the "lost art" would enjoy a reactionary favoritism. He thought it was really saying too much, with our present extreme prejudices against venesection, that we should assume to be so much wiser than our fathers, who had lent their approval to a custom that had been sanctioned by ages of experience. Might we not, in going to the opposite extreme, do violence to a principle that was really conservative in its nature? It was the extreme view taken either way that was likely to occasion untoward results. It was the fashion of the present day to decry this kind of practice, and, like many other fashions, it was founded upon ideas that would not stand the test of reasoning investigation. Even disease itself, in some form or other, had often become fashionable. An instance in point was cited in reference to Louis XIV. of France, who was afflicted with a loathsome disease, with which the people of his court soon became fashionably afflicted, and which many of the higher classes affected. There was as much tyranny exercised by the opinion of an eminent authority (eminent because it was *foreign*) in support of improbable or questionable medical views, as there was in the mandates of the queen of fashion, foremost among whom in her time was the Empress Eugenie, and to which every woman felt herself compelled to yield, or else forego her influence and standing in the fashionable world. So with a majority of the medical profession, who abandoned voluntarily—or felt compelled so to do—old and once cherished opinions, in order that, by following new theories, they might not render themselves conspic-

uous by an adherence to the ancient régime. It was simply the fashion of the day. The speaker said that, though he was no prophet, nor the son of a prophet, the time was fast coming, if it were not already at hand, when a reaction would ensue in favor of the therapeutical effect of blood-letting, and the idle lancet be again resorted to as one of the main reliances in the treatment of many forms of disease, particularly in the acute stages; for, continued he, history is constantly repeating itself, and knowledge runs in a circle. There were times to bleed and times not to bleed, and these distinctions, wherein our fathers erred, we of this day and time are enabled to recognize readily and turn to valuable account. When we had acquired a more accurate knowledge of diseases, the tendency to run into extremes would be less characteristic of the profession if not avoided altogether.

The substitute for the lancet nowadays consisted in the administration of medicines that had a tendency to reduce the fulness, frequency, and power of the heart's action, and the extreme use of these was more dangerous than the one decried. Women in child-bed had often lost immense quantities of blood, more than an old-time physician could ever think he had occasion to draw, hemorrhages from various causes, and the continued and immoderate use of the lancet, in many recorded cases, in which no more blood came away because there was too little left to run, could be cited, and yet recovery followed, and the life-current was speedily introduced under a nourishing and sustaining after-treatment.

Cases of acute diseases, and those in other stages of development, were cited to prove the efficacy of a timely abstraction of blood from a vein, and individual cases were likewise produced, in which this feature of practice was proven to be the only one which insured a further lease of life or ultimate recovery.

ARMY STAFF RANK.

Dr. J. M. TONER, of Washington, Chairman of the Committee to Memorialize Congress on the Rank of the Medical Staff of the Army, offered the following, which was adopted:

The Committee (of one from each State) on the Rank of the Medical Department of the Army respectfully report: That, as soon as possible after the adjournment of the Detroit meeting of this Association, a form of petition to Congress was agreed upon, in which the unsatisfactory position of the medical corps was briefly stated, and the nature of the relief asked for indicated. This petition was circulated among the physicians of the several States by the members of the committee, and was very extensively signed. In connection with the petition, an explanatory pamphlet was widely distributed. It contained a "brief statement of the facts" connected with the subject, and a draft of a bill, the passage of which would have placed the medical corps on a satisfactory footing in the matter of rank. A copy of the pamphlet is herewith submitted. The bill, which was prepared after consultation with the Surgeon-General, and a number of the other medical officers of the army, did not propose to alter the number of medical officers now allowed by law, but merely provided that after thirteen years' service, medical officers should have the rank of major; after twenty-three years' service, the rank of lieutenant-colonel, and, after thirty years, the rank of colonel. Immediately after Congress convened last December, this bill was duly introduced in both houses, and in each read twice and referred to the Military Committee. During the rest of the session every effort was made to secure its favorable consideration. Three petitions

from the several States were duly presented; copies of the explanatory pamphlet were sent to each Senator, and members were personally conferred with. These efforts were so far successful that before the month of December, the Military Committee of the House of Representatives agreed to report the bill to the favorable consideration of the House; but the press of other measures of greater political interest caused this to be postponed from time to time, until the session came to a close, without any action having been taken. It is believed, however, that the medical profession of the United States will not be satisfied with this inaction. Your committee have certainly found a gratifying unanimity of sentiment on the subject among the physicians of all parts of the country, and have been led to believe that it is their earnest desire that this Association shall continue to urge the claims of their brethren of the medical staff of the army upon Congress until such a law is enacted as will secure to them the share of rank we believe they ought to enjoy.

It is hoped that the matter may be pressed at the next session of Congress with a chance of better success than it had at the last session. Much assistance will doubtless be rendered by those physicians who are personally acquainted with members of Congress by explaining the merits of the appeal made, but this Association certainly ought also to continue its efforts; and the passage of the following resolutions is therefore recommended:

Resolved, That this Association learns with regret that no action was taken by the last Congress upon its recommendation in behalf of the medical department of the United States army, and that we respectfully renew our petition, that Congress will enact such a bill for the benefit of the medical department of the army as will secure to its officers that share of rank and promotion to which we consider they are entitled, and which should be at least fully equal to that enjoyed by any other staff corps, or by the medical corps of the army.

Resolved, That a committee of five be appointed to call the attention of Congress to this subject, and the petitions which were forwarded to the last Congress by the physicians of the United States.

ADDRESS ON PRACTICAL MEDICINE.

PROF. AUSTIN FLINR, of New York. Chairman of the Section on Practical Medicine, next made his report on the discoveries during the last year, discussing the subjects of alcoholism, motor centres, new remedial agents, transfusion, and concluding with remarks on the natural history of crime. The changes of alcohol in the system, and its medicinal uses were dwelt upon at some length. Some held that alcohol passes into blood and is expelled through the excretories unchanged, while others denied this and held that it was appropriated by the animal economy. Well-conducted experiments, however, went to prove that when alcohol was thus taken into the system, the proportion excreted by the kidneys, lungs, and skin is exceedingly small, the greater part being destroyed in the body. What becomes of it? This remains to be answered by farther experimental researches. Six hundred grains of absolute alcohol can be disposed of without injury to the bodily functions of a healthy adult. It is accordingly employed in the treatment of many conditions of disease, though its use is not based upon any ascertained facts concerning its elimination.

In regard to the subject of transfusion, he remarked that, while there were many experiments performed in the transfusion of the blood of one animal into the

veins of another of unlike genus, and of the blood of a lamb into the veins of a man, himself a physician, in one instance, there were certain curious results noticed, but nothing positive had been elaborated that would justify the positive advocacy of any reliable feature or theory of practice. The subject was not without interest or promise, however, and afforded an ample field for any one whose zeal for the advancement of medical knowledge in that direction was equal to the task of an investigation, and which could hardly fail, eventually, to be of signal advantage to the profession.

The closing feature of the paper had reference to the natural history of crime, in which the query was announced concerning the possible connection of individual tendencies to the commission of crime with corresponding diseased conditions of the organization. It was very ingeniously and elaborately put forth, together with the possibility, finally, of medical treatment for such conditions, underspecific classifications, as in the case of real diseases. This, of course, implied a discussion of the responsibility for criminal acts, which should, however, offer no hindrance to enlightened investigation.

The report was adopted and referred to the Publishing Committee.

INTERNATIONAL CONFERENCE AGAIN.

Dr. J. M. TONER made a report suggesting the organization of an International Medical Association, in which the profession of America should be represented at the meeting in Brussels. The report was referred to the Committee on Nominations.

On motion, the morning of the following day was apportioned as follows: Lecture on Surgery, by E. M. Moore, of New York, at 11 o'clock; on Obstetrics, at 11.40, by Prof. Byford, of Chicago; and on Hygiene, by Dr. Bowditch, of Boston, at 12.20.

THE ASSOCIATION MEDAL.

The committee appointed by the Association, at its meeting last year, to select a medal to be presented to each member, reported that it had selected a die with the vignette of Dr. N. S. Davis, the founder of the Association, on the obverse side, and with the name and date of said Society upon the reverse; and that it had arranged for the manufacture of the medal, in bronze, at the mint in Philadelphia, at a cost of \$1.12 each, the twelve cents being for postage. The report was received, and the committee instructed to order 200 of the medals.

A resolution of sympathy for Dr. John B. Jackson, of Lexington, who was ill at his hotel, was passed, when the Association adjourned until 9.30 on Thursday morning.

THURSDAY, MAY 6—THIRD DAY.

The Association was called to order by the President, Dr. W. K. Bowling. In accordance with the request previously made by Dr. Seguin the following gentlemen were appointed delegates to the Medical Convention at Brussels: Drs. J. A. Adrian, J. C. Hutchinson, J. C. Huff, E. C. Harwood, H. D. Hulton, and H. R. Warner.

A NEW PRIZE.

DR. SEELYE, of Alabama, offered a prize of one hundred dollars for the best essay on Bright's disease. Report accepted and referred.

THE CANADA MEDICAL ASSOCIATION.

DR. WOOD offered the following: *Whereas*, the Canada Medical Association has adopted and forwarded to this Association the above resolution, be it

Resolved, that a committee of thirteen be appointed

by this Association, whose duty it shall be to confer with a like committee of the Canada Medical Association, at such time and place as agreed upon by the joint committee of the Association.

The following gentlemen were appointed the committee:

Dr. S. D. Gross, Pennsylvania; Dr. John T. Hodgen, Missouri; Dr. Austin Flint, New York; Dr. Willoughby Walling, Kentucky; Dr. T. C. Lane, California; Dr. Wirt Johnson, Mississippi; Dr. Wm. Brodie, Michigan; Dr. J. M. Toner, Washington; Dr. T. D. Cunningham, Virginia; Dr. E. Andrews, Illinois; Dr. Wm. A. Atkinson, Pennsylvania; Dr. H. I. Bowditch, Massachusetts; Dr. Roberts Bartholow, Ohio.

Dr. FLINT offered a resolution of sympathy for Dr. Lewis Rogers, of Louisville, prefacing it with appropriate and eulogistic remarks.

The following gentlemen were made members by invitation:

Drs. C. J. Walton, Kentucky; E. A. Wagner, Kentucky; Tucker, Kentucky; C. J. Renfro, Kentucky; O'Neal, Kentucky; Sweeney, Kentucky; N. J. Leak, Kentucky; K. D. Hawley, Indiana; W. C. Hall, Indiana; Fred. Pointer, Indiana; W. W. Hall, Mississippi; F. Pointer, Tennessee.

A memorial of Dr. E. M. Curtis was received from the Sacramento Medical Society, and was placed on file.

The treasurer's report showed a cash balance of \$30,022.41.

THE McDOWELL MEMORIAL FUND.

Dr. J. Marion Sims, of New York, as Chairman of the Special Committee appointed to devise plans for the establishment of the McDowell Memorial Fund, offered the following:

Whereas, it is universally acknowledged that the late Ephraim McDowell, of Kentucky, was the originator of the operation of ovariectomy; and,

Whereas, we believe that proper measures should be instituted to commemorate this great achievement and do appropriate honor to its author; therefore,

Resolved, That this Association recommend to each of its members and to the profession generally to contribute annually such sums as they may think proper, until the amount of \$10,000 shall be accumulated, which shall be known as the McDowell Memorial Fund, the interest of which shall be devoted to the payment of prizes for the best essays relating to the diseases and surgery of the ovaries.

Resolved, That this Fund shall be invested by trustees, to be appointed by the Association, and subject to such regulations as it may desire.

Resolved, That the Association shall elect a board of three trustees, whose duty it shall be to carry out the object of these resolutions and whose term of office shall continue five years.

Resolved, That this Association will leave to the State of Kentucky the grateful privilege of providing a local memorial to the memory of Dr. McDowell. Respectfully submitted, J. Marion Sims, New York; Washington L. Atlee, Pennsylvania; W. T. Byford, Illinois; J. M. Keller, Kentucky.

Dr. Gross made some remarks concerning the justice of the claims of Dr. McDowell to the origination of the operation in question, after which he subscribed one hundred dollars to the Fund.

CENTENNIAL CONFERENCE.

Dr. Gross, as chairman of the Centennial Medical Commission of Philadelphia, announced that it was designed to hold an International Medical Conference in Philadelphia during the Centennial celebration. He then read from a circular the purport and plan of

the movement. The Philadelphia County Medical Society, embracing nearly two hundred members, many of them of high professional distinction, animated by a just spirit of patriotism, and an earnest desire to unite with its fellow-citizens in celebrating the centennial birthday of American Independence, have projected an International Medical Conference. Arrangements have been perfected to hold the session during September, 1876. Addresses will be then read illustrating the advance in the profession during the past one hundred years. Invitations have been sent all over the world. The hospitalities of Philadelphia are proffered. Delegates will be expected from the Association and from State Societies.

THE REPORT OF THE JUDICIAL COUNCIL.

Dr. S. W. BENHAM, of the Judicial Council, made the following report:

The Judicial Council of the American Medical Association would respectfully report as follows:

In reference to the difficulties existing between the Allen County Medical Society, of Indiana, and the Fort Wayne Medical Association, of Indiana, we would respectfully refer the whole subject to the State Medical Society of Indiana for adjudication. In reference to the Arkansas State Medical Association, the following resolution was adopted, to wit: That the delegates of the said State Medical Association should be admitted to proper registration at this meeting of the American Medical Association; also that the protest of the local societies of Arkansas be referred to the State Society for adjudication.

The name of Dr. Sweeney, as a delegate from the State Medical Society of Kentucky, was rejected, for the simple reason that that State had already sent its full complement of delegates to this Association.

The following resolution in regard to delegates from the College of Physicians and Surgeons of Louisville was passed:

That the list of delegates appointed by the society known as the College of Physicians and Surgeons of Louisville, Ky., consisting of Drs. Turner Anderson, Wm. Bailey, D. W. Yandell, Lewis Rogers, and G. W. Holland, are the lawful and proper delegates from that society, and that the Committee of Arrangements should correct the registry of members for this meeting of the Association in conformity thereto.

Also, in reference to the Academy of Medicine of Louisville, that the action of the Committee of Arrangements, in declining to receive and register the names of all the delegates appointed by the society known as the Louisville Academy of Medicine, is approved as correct, simply because it is believed that the Association had already received from the State Medical Society of Kentucky, and the local societies in Louisville having a prior active existence, the full number of delegates to which the profession of Louisville are entitled under the present constitution of this Association.

ON TRANSFUSION.

Prof. E. M. Moore, of Rochester, N. Y., read a paper on the above subject, of which the following is an abstract:

Various methods of proceeding have been proffered by the disciples of transfusion. When first successfully performed it excited the highest hopes of friends, and attracted the attention of the great, who were interested spectators of the operation, and who predicted for it great therapeutic value. They indulged themselves in visions of life transmitted to the moribund patient from the superabundant supply of friends who would interpose a timely supply of healthy blood, and

they, in their new-found zeal, almost imagined that death had been practically vanquished, and that youth by this means would be insured to the aged and decrepit. But the practice in this early day did not fulfil the expectations predicted of it, and, after a time, it ceased to be regarded as having any practical significance. In more recent times the subject had been revived, and the attention of the profession fixed upon it by a published article from a celebrated physician in Geneva, who described the operation as practised in St. Petersburg, which had not only been attended with marked success, but had enlisted the attention of royalty itself, together with that of the most distinguished physicians of the Russian empire. The operation was designed for the relief of those losing blood in battle, but soon became of more extended application, and old hopes soon became revived in modern science. Yet, as the speaker remarked, it must be confessed that our knowledge, even to the present time, concerning the therapeutic value of blood transfusion is decidedly limited.

This operation, with all the wonderful advantages claimed for it, was not a sudden discovery, but grew out of the experiments of Dr. Christopher Wren, in injecting medicinal substances into the veins; while this, in turn, grew out of Harvey's discovery of the circulation of the blood, in the early part of the seventeenth century. In 1665, two continental physicians prosecuted a series of experiments upon the lower animals, in respect to blood transfusion, but without any notable degree of success. Laner, another physician, took up this line of investigation in the same year. He connected the carotid artery of one dog with the jugular vein of another, and varied the operation at different times in respect to others; and, though not remarkably successful in these experiments, he thought, upon the whole, that he detected some results which were favorable to the theory.

Another experimenter passed the blood of a calf into the veins of a dog, but such being an infringement upon the laws of nature, the result proved a failure. The first operation of transfusion in the case of a human being occurred in Paris. A young man sixteen years old, who had been suffering two months from an obstinate fever, had introduced into his veins eight ounces of arterial blood from a lamb, and, notwithstanding the shock to his system, all unfavorable symptoms passed away, and he finally recovered. The case of a man aged forty-five years was cited, into whose veins were introduced ten ounces of the arterial blood of a lamb. He was not at all incommoded by the operation, and even went the next day to have the operation repeated. Another man, reduced by dysentery, was transfused with the blood of a calf, and revived in twenty-four hours, but when it was found necessary to repeat the process, such proved of no avail. Another case cited referred to that of an insane man, into whose veins were introduced, at one time, ten ounces of the arterial blood of a calf, and at another six ounces more. He seemed somewhat better, in consequence, and a third transfusion was made, in which a larger quantity of blood was injected, and finally, upon recovering his reason, was supposed cured, but in a few days thereafter gave up the ghost.

Such fatal experiences at length checked inquiry and enthusiasm in this direction, and as late as the year 1868 interest in transfusion had almost entirely disappeared.

In recounting the later experiments of transfusion, reference was made to the variety of procedure in such investigation, in which arterial blood was introduced

into the veins, venous blood into the arteries, and each kind of fluid, with its fellow, as introduced from animals into the human system, and from one human being to another. Instances were also given in which defibrinated blood was injected into both arteries and veins. In the experiments thus enumerated, reference was also made to the direct admixture of the blood of one animal of different species or genus with that of another, as, for instance, the blood of birds with that of quadrupeds, quadrupeds with birds, that of cold-blooded animals with the warm-blooded, and *vice versa*; but only in those nearest of kin or allied in species were the results proved to be favorable, in which the vital functions were restored, and the new forces re-established.

The danger attending the original experiments was the accidental introduction of air into the veins, the result of which, in all cases, is immediate death. There was also another drawback to the success of this operation at that time, which was the coagulation of blood before it could be speedily introduced from the veins of the donor to those of the recipients. And accordingly the minds of those engaged in the prosecution of this matter were taxed to invent instruments and appliances by means of which these difficulties could be overcome. Improvements in this direction had gone on until at present the apparatus in use was found to answer all practical purposes, and all liability to the accidental ingress of air into the veins was avoided, while it insured such a speedy transfer of blood from the donor to the recipient as effectually prevented any tendency to thickening or coagulation thereof. Engravings of the several kinds of instruments used for this purpose were exhibited and explained.

To give some idea of the manner of using the instrument preferred by the speaker two boys were seated on the stage, close together, one representing the donor, from whom the blood was to be taken, and the other the recipient of the life-giving fluid. The latter, however, as the speaker observed, must always occupy the recumbent position, and the former that of the sitting. The arms of both were extended and made to approximate to each other, the operator standing behind them in order to demonstrate, and which position, he remarked, was the position the surgeon should assume in this operation. First, the skin over the cephalic vein of the recipient must be clipped, to lay bare that vessel, which was to be further isolated from adhering tissues in order to be gotten at successfully. That of the donor was to be held in ready juxtaposition for the operation. The instrument consisted of a small silver tube four or five inches long, with a small gutta-percha bag adjusted to an attachment at its centre. When one end of this instrument was introduced into the vein of the donor, the speedy filling of which was to be insured by a ligature above the bend of the arm, the bag would soon be filled with blood. The connection of this with the vein was then to be severed, and the contents of the bag introduced gently through the other end of the instrument, which, in the meantime, was to be inserted into the bared vein of the recipient.

The consideration of this subject seemed to be exhausted, so far as the present state of knowledge upon the matter is concerned, which yet affords a wide, interesting, and useful field for investigation.

UTERINE FIBROIDS,

by DR. BYFORD, of Illinois, occupied the remainder of the session. It was also well received and referred for publication.

The Association then adjourned until 9.30 o'clock on Friday morning.

FRIDAY, May 7—FOURTH DAY.

The Association was called to order at 9.30 P.M. President W. K. Bowling in the chair. Dr. Keller, of Ky., offered the following, which was adopted:

Resolved, That all motions involving the authorization of expenditure of funds, except the expenses of the committee on publication and salary of the secretary, shall be referred to the judicial council for recommendation before final action be taken upon them by the Association.

DELEGATES TO THE CANADIAN CONVENTION.

The following gentlemen were appointed delegates to the Canadian Medical Convention:

Dr. S. D. Gross, Pennsylvania; Dr. Turner Anderson, Kentucky; Dr. Willoughby Walling, Kentucky; Dr. Wm. B. Atkinson, Pennsylvania; Dr. Wm. Brodie, Michigan; Dr. E. T. Easley, Texas.

TRUSTEES OF THE MCDOWELL MEMORIAL.

The following gentlemen were chosen members of the McDowell memorial.

Dr. W. L. Atlee, Philadelphia; Dr. W. H. Byford, Chicago; Dr. J. D. Jackson, Danville, Ky.; Dr. J. M. Keller, Louisville; Dr. J. Marion Sims, the president, ex-officio chairman.

OFFICERS FOR THE ENSUING YEAR.

Dr. James R. Wood, chairman of the Nominating Committee, made the following report:

President—Dr. J. Marion Sims, of New York.

Vice Presidents—First, Dr. John D. Jackson, of Kentucky; second, Dr. Samuel Lilly, of New Jersey; third, Dr. N. Pinkney, of United States Army; fourth, Dr. S. D. Seeley, of Alabama.

Treasurer—Dr. Casper Wister, of Pennsylvania.

Librarian—Dr. William Lee, of District of Columbia.

Committee on Library—Dr. Johnson Eliot, of District of Columbia.

Assistant Secretary—Dr. Richard J. Dungleison, of Pennsylvania.

Committee on Arrangements—Drs. William Pepper, Chairman; Frank Maury, Albert Fricke, A. Hewson, S. W. Gross, William Goodsell and — Drysdale.

Committee on Publication—Dr. F. G. Smith, — Drysdale, Albert Fricke, and Wm. B. Atkinson, all of Philadelphia.

OFFICERS OF SECTIONS.

Practice of Medicine, Materia Medica and Physiology—Dr. F. G. Smith, Pennsylvania, chairman; Dr. B. A. Vaughn, of Mississippi, secretary.

Obstetrics and Diseases of Women—Dr. Samuel C. Busey, of District of Columbia, chairman; Dr. R. Battey, of Georgia, secretary.

Surgery and Anatomy—Dr. Alonzo Garcelon, of Maine, chairman; Dr. E. T. Easley, of Texas, secretary.

Medical Jurisprudence, Chemistry, and Physiology—Dr. E. L. Howard, of Maryland, chairman; Dr. E. L. Hurlburt, of Illinois, secretary.

State Medicine and Public Hygiene: Dr. R. C. Kedzie, of Michigan, chairman; Dr. Ezra M. Hunt, of New Jersey, secretary.

The following were appointed representatives in this section from their respective States: J. B. Gaston, Alabama; D. A. Linthicum, Arkansas; T. M. Logan, Colorado; B. H. Cattlin, Connecticut; L. B. Bush, Delaware; F. Howard, District Columbia; W. A. Love, Georgia; H. A. Johnson, Illinois; Geo. Sulton, Indiana; A. J. Fields, Iowa; D. G. Mottram, Kansas; Turner Anderson, Kentucky; S. M. Bemiss, Louisiana;

S. H. Weeks, Maine; James A. Stuart, Maryland; H. J. Bowditch, Massachusetts; A. B. Stuart, Minnesota; — Armistead, Mississippi; Frank G. Porter, Missouri; J. H. Peabody, Nebraska; J. W. Parsons, New Hampshire; E. M. Hunt, New Jersey; A. N. Bell, New York; T. J. Quinn, Ohio; H. Bettinger, Oregon; Wm. P. Knox, Pennsylvania; E. M. Snow, Rhode Island; R. A. Kinlock, South Carolina; J. H. Vandiman, Tennessee; J. M. Fort, Texas; J. L. Caball, Virginia; A. T. Woodward, Vermont; H. P. Strong, Wisconsin; John Frissell, West Virginia; Wm. A. B. Norcom, North Carolina; John S. Billings, U. S. Army; Joseph Wilson, U. S. Navy.

The following is the Committee on Necrology: S. O. Chinn, Maryland, Chairman; B. R. Jones, Alabama; A. H. Scott, Arkansas; Henry Gibbon, Jr., California; G. W. Russell, Connecticut; L. P. Bush, Delaware; W. W. Johnson, District of Columbia; A. J. Kirksey, Georgia; W. M. Chambers, Illinois; Thad. M. Stevens, Indiana; J. W. Baker, Iowa; D. W. Stormant, Kansas; L. P. Yandell, Sr., Kentucky; Alonzo Garcelon, Maine; A. Sayer, Michigan; A. W. Stinchfield, Minnesota; Wm. M. Compton, Mississippi; A. J. Steele, Missouri; J. H. Peabody, Nebraska; J. H. Wheeler, New Hampshire; John Blain, New Jersey; W. H. Bailey, New York; George Mitchell, Ohio; W. C. Warriner, Oregon; Horatio C. Wood, Pennsylvania; C. W. Parsons, Rhode Island; A. N. Talley, South Carolina; John H. Callender, Tennessee; S. D. Thurston, Texas; Levin S. Jaynes, Virginia; R. W. Hazlett, West Virginia; N. M. Dobson, Wisconsin; J. J. Woodward, U. S. Army; S. F. Wilson, U. S. Navy; O. J. O'Heagan, North Carolina; — Bronson, Massachusetts.

JUDICIAL COUNCIL.

The terms of a portion of the Judicial Council expiring at this meeting, the following were appointed to take their places:

Dr. Louis S. Jaynes, of Virginia; Dr. R. N. Todd, of Indiana; Dr. Robert Battey, of Georgia; Dr. James E. Morgan, District of Columbia; Dr. Thomas B. Flaylor, of New Jersey; Dr. Silas N. Bentram, of Pennsylvania; Dr. A. Dunlap, of Ohio.

PRIZE ESSAYS.

The following is the Committee on the Determination of Prize Essays:

Dr. Samuel D. Gross, Pennsylvania; Dr. F. G. Smith, Pennsylvania; Dr. Alford Stiltz, Pennsylvania; Dr. E. Wallace, Pennsylvania; Dr. H. C. Wood, Pennsylvania.

CLIMATIC INFLUENCES.

Dr. Franklin Staples, of Minnesota, was appointed to report on the influence of the Minnesota climate on pulmonary diseases; Dr. Charles Demmon, of Colorado, to report on the same in Colorado; and Dr. E. T. Sabal, of Florida, to report on the same in Florida.

A NATIONAL COUNCIL OF HEALTH.

DR. BOWDITCH, of Boston, made some extended remarks upon the practicability of establishing a National Council of Health. After stating the results of his inquiries from the Secretaries of Health Associations in the different States, and giving their generally favorable view of the project, he remarked that State medical boards should be composed of both professional and lay members. In that of his own (Massachusetts), the board consisted of three physicians and four laymen, the latter being citizens eminent for their intelligence and public spirit, one of whom was a civil engineer, who stood at the head of his pro-

fession; another was a noted historical writer, while a third was a wholesale leather-dealer, who was valuable by his ability to win over the belligerent butchers, who generally fought against sanitary supervisions. Concerning the practical advantages to be derived from the deliberations and the authority of a National Council of Health, the speaker proceeded to specify some of these in the way of general utility to the whole country. In the broad zone of territory extending from Maine to Florida, and from ocean to ocean, there are fertile prairies, vast morasses, lagoons, swamps, etc., and all those portions of our territory must be brought under scientific manipulation in order to fit them for healthy abode. In the past, as at the present time, there are hecatombs of men sacrificed from ignorance of hygienic laws, and to enable the Government to bring all this under the supervision of a sanitary board is not the work of a moment. He thought that there should be a department of hygiene created by the Government, which should be represented in the Presidential Cabinet. This would embrace the oversight of hospitals, insane asylums, forts, camps, barracks, medical storehouses, etc., to say nothing of the general supervision of that department over its ramified interests throughout the land, in which would be embraced the study and observation of health, diseases, epidemics, climatology, meteorology, etc. In the event of the establishment of this great enterprise, every State should have a counsellor, and all be present at any meeting; some at least would be able men. Each counsellor should hold office for five years, and be re-elected if such should be thought desirable. In addition, the speaker suggested that this association should have the right to select, every five years, four men as counsellors at large for the nation, to be chosen from four divisions of the country, each man to serve five years. And finally, the National Government should be represented in the council by the health secretary, surgeon-general, and signal officer, that they may be able to answer questions pertaining to their several fields of labor. This would take from this association some right of nominating in the national council, but the association would still stand higher in having four representatives. The fact of the constant change of the place of meeting must compel the association to be more or less sectional in its action, however much it may claim to be a national body. This health association, composed of one from the medical organization of each State, would be of national significance, and as a national body, transacting public business, its members should have reasonable compensation and mileage granted them. But the great object now was to begin to educate the people up to a knowledge of their wants in this direction, and to this end the following resolutions appended to the paper read by the speaker:

Resolved, That each year, until otherwise ordered, the president-elect and the permanent secretary be directed to appeal, in the name of this association, to the authorities of each State where no State Board of Health exists, urging them to establish such boards.

Resolved, That the permanent secretary is hereby directed annually to report the names of the States where boards of health exist, and also of those which decline to establish them; said report to form a part of the annual proceedings of the association.

PRIZE ESSAYS.

The Committee on Prize Essays was not prepared to make a report.

OZONE AND THE SIGNAL SERVICE.

The chief of the United States Signal Service was requested, if it is within his power, to note in his daily weather reports the quantity of ozone in the atmosphere in different sections of the country.

SALARY OF ARMY PHYSICIANS.

On motion of Dr. Westmorland, the Association unanimously adopted a resolution recommending to Congress that the salaries of the physicians of the army be increased.

PROF. JAMES McNAUGHTON, OF ALBANY, N. Y.

Dr. N. S. DAVIS moved the following:

Resolved, That in the death of the late Dr. James McNaughton, of Albany, N. Y., we recognize the loss of one of the earliest, oldest, and most distinguished members of this Association; one who for more than half a century had been a noble example of the upright citizen, the untiring physician, the enthusiastic teacher, and the true Christian gentleman.

Resolved, That a copy of the foregoing resolution be communicated to the family of the deceased.

Dr. Gross, having in a few remarks testified to the virtues of the deceased, the resolutions were passed by a rising vote.

The time for adjournment having arrived, several complimentary speeches were made, and the usual resolutions of thanks passed.

The Association adjourned, to meet in Philadelphia the first Tuesday in June, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from May 2d to May 8th, 1875.

HEAD J. F., Surgeon.—Announced as Medical Director of the Department. G. O. 3, Department of the South, April 30, 1875.

WEISEL, D., Assistant Surgeon.—Granted leave of absence for one month. S. O. 56, Department of the South, May 1, 1875.

SEMG, B. G., Assistant Surgeon.—Assigned to duty at Fort Yuma, California. S. O. 25, Department of Arizona, April 12, 1875.

THE FIFTY-FOURTH ANNUAL REPORT OF THE NEW YORK EYE AND EAR INFIRMARY is a pamphlet of sixty-four pages. 7,464 cases of diseases of the eye, 2,439 of diseases of the ear, and 583 of diseases of the throat have been treated during 1874; a total of 10,486, or 185,963 which have been treated since the founding of the infirmary in 1820. 1,131 operations were performed during the year. The report contains a list of fifty cases of disease of the eye, ear, face, and throat which had been treated by electricity, of which twenty-two received decided benefit, thirteen no benefit, while in fifteen cases the remedy did not have a fair trial. Dr. Derby's report of the results in thirty-eight operations for cataract performed at the infirmary, is included in the pamphlet, and analytical reports are made of the different departments. It is mentioned that notwithstanding the widespread prevalence of epidemic diphtheria in the city, especially among the poorer population, only a single case of pharyngeal diphtheria and two of diphtheritic paralysis of the velum palati are to be found among the cases treated in the throat department.

Medical Items and News.

UNIVERSITY MEDICAL COLLEGE, NEW YORK.—Prof. Alfred C. Post has resigned the chair of surgery in the medical department of the University of New York, and has been elected Emeritus Professor of Clinical Surgery. Prof. John T. Darby, formerly professor of anatomy and surgery in the medical department of the University of South Carolina, has been elected to fill the vacancy.

N. Y. EYE INFIRMARY.—A suit for damages to the amount of \$100,000 has been commenced against the New York Eye Infirmary and R. H. Derby, one of the surgeons, for alleged improper treatment of a patient's eyes, whereby it is claimed blindness resulted. It is fair to presume that the institution and the surgeons are entirely safe.

A MISTAKE IN DIAGNOSIS.—Two prominent physicians of Kingston, Ulster Co., N. Y., have been indicted by the Grand Jury of that city for mistaking a case of small-pox for chicken-pox, thus causing the spread of the former disease.

SUSAN DIMOCK, M.D., the talented female physician of Boston, was one of the victims of the Schiller wreck. For a long time she was the resident physician of the New England Hospital for Women and Children.

JOSEPH MATHER SMITH, M.D.—It is the intention of Dr. Gouverneur M. Smith to present a fine portrait of his father to the Academy of Medicine, on the occasion of the inauguration of the new building, on the 20th. Dr. J. M. Smith was one of the founders of the Academy and was its President in 1854.

PROF. S. D. GROSS, of Philadelphia, on the eve of his departure from Louisville, after attending the meeting of the American Medical Association, was the recipient of a handsome team of Kentucky thoroughbreds, the impromptu gift of his medical friends and citizens of Louisville. The idea was suggested by a visit to the famous stock-farm of Col. McFerran, and a subscription for the purpose was quietly started on the spot. Dr. Gross for many years was professor of surgery in the Louisville University, and during that time made host of friends among his medical brethren and the citizens. The team is valued at \$800.

DEATH DURING INHALATION OF ETHER.—*The Lancet* of April 17 mentions that a lad of sixteen, when about to undergo a slight surgical operation in the Manchester workhouse, expired soon after the inhalation of ether had been commenced. Twice before had chloroform been used, but it had worked so badly that on this occasion ether was substituted. The verdict rendered at the inquest was, "Died of syncope."

COLLEGE OF PHYSICIANS AND SURGEONS.—At a quarterly meeting of Trustees of College of Physicians and Surgeons, on 11th inst., Alonzo Clark, M.D., was unanimously elected President of the College. Thos. F. Cock, M.D., was elected Trustee in place of Edward Delafield, M.D., deceased. Francis Delafield, M.D., was appointed adjunct Professor of Pathology and Practical Medicine.

DANIEL HANBURY, F.R.S., long and well known as a writer and investigator on pharmacological subjects, and associate author of the "Pharmacographia," died at his residence in London, on the twenty-fourth of March, in the fiftieth year of his age.

THE POPULATION OF GERMANY is about the same as that of the United States—forty millions. Last year Germany graduated six hundred and sixty physicians, and the United States three thousand, and yet some think it strange that it takes a young physician so long to become established.

DR. WERNICH, *privat-docent* in Berlin, has been appointed by the Japanese Government teacher of Clinical Medicine in the Medico-Chirurgical School at Jeddo.

THE NORTH-WESTERN OHIO MEDICAL ASSOCIATION.—The meeting of this Association has been postponed to May 19 and 20, owing to the meeting of the American Medical Association on the 4th, and will take place, as appointed, at St. Mary's.

MEDICAL SOCIETY OF NEW JERSEY.—The next annual meeting of the Medical Society of New Jersey will be held in Congress Hall, at Atlantic City, Tuesday and Wednesday, May 25th and 26th, 1875, commencing at 7.30 P.M. on Tuesday. Delegates are requested to present their credentials at that time. At 8 o'clock precisely, the Annual Address by the President, Dr. Larison, will be delivered. After the address, the President will announce the committees, etc.

On Wednesday, after the transaction of the usual routine business, essays will be read by Dr. H. R. Baldwin, of New Brunswick; Dr. J. W. Ward, of Trenton, "The Causes of Insanity;" R. M. Bateman, of Cedarville, "Legislative Protection," which will be followed by voluntary communications and reports of interesting cases.

After the adjournment on Tuesday evening, there will be a banquet in Congress Hall, given to the members of the Camden Medical Society. A special train of cars have been secured to convey the delegates and members [delegates from corresponding societies are included] from Camden to Atlantic City with free passes. The train will leave Camden at 3.40 o'clock, P.M.; Vine Street Ferry, Philadelphia, at 3.30. This train will run through in two hours. Arrangements have been effected with the Penn. R. R. for orders for commutation tickets. Members desiring orders for commutation should apply for them to the Secretary (Dr. Pierson) before the 22d inst. Congress Hall will open two weeks earlier than usual for the special accommodation of the Society. The hotel will accommodate five hundred guests. J. V. Schenck, T. F. Cullen, I. W. Snowden, H. G. Taylor, J. R. Stevenson, Committee of Arrangements.

ERRATUM.—In the first lecture of Dr. Arnold, No. 233, 290, 14th line from bottom, for "one-tenth" read "three-tenths."

WEEKLY BULLETIN OF MEETINGS OF MEDICAL SOCIETIES.

Monday, May 17.—Obstet. Sec. of the Acad. of Med., at house of Dr. Isaac E. Taylor; Medico-Chirurgical Society; N. Y. Society of Electrology and Neurology; Pathological Society of Brooklyn.

Tuesday, May 18.—N. Y. Obstetrical Soc.; N. Y. Dermatological Society; Med. Soc. of the County of Kings; Newark Medical Association.

Thursday, May 20.—N. Y. Academy of Medicine (first meeting in the rooms at 12 West 31st Street); Med. Assoc. of the Eastern Dist. of Brooklyn.

Friday, May 21.—Medical Library and Journal Association; Anchylosis of the Temporo-Maxillary Articulation of long Standing; Displacement, Fracture, Atrophy of the Muscles, Treatment by Dr. D. H. Goodwillie.

Original Communications.

CONIUM: AND ITS USE IN DISEASES OF THE EYE.

By EDWARD CURTIS, A.M., M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

[Read before the New York County Medical Society, April 26, 1875.]

PART I.

PERHAPS none of the old-time drugs has such a curious history as conium. Known from antiquity as a mighty poison, it was yet but little used as an internal medicine, until about a hundred years ago. Then, through the treatise of Stoerck, it mounted to the pinnacle of fashion, only to fall, after many years, into almost complete disuse. From this comparative oblivion it has lately been rescued, and is now again on trial for its life, with strong foreshadowings that the jury will disagree.

The key to this strange history lies in two facts, which cannot be too widely made known. These are, first, that the active principle of the hemlock is so volatile that it may easily be entirely driven off in the very making of medicinal preparations: and, secondly, that the leaf of the plant, which has been and still is a good deal used by the pharmacist, contains at best but a very small percentage of the alkaloid, and may lose even this in the mere drying. Hence the curious circumstance has happened, that in this case the skill of modern pharmacy during long years only resulted in supplanting the crude, but poisonous juice of antiquity, by preparations which, from their innocence, might as well be made from cabbage-heads as from the deadly spotted hemlock. And even to-day the shelves of the druggist teem with preparations bearing the name of conium, which are nearly, and often even wholly inert. Some are so because the Pharmacopœia persists in authorizing processes that *can* give no other result: but also, it is well to know, even the one good preparation—the new fluid extract of the green fruit—does not always escape emasculation at the hands of its maker. Thus I have given at a dose sixty, and even one hundred minims of samples of this extract, made by responsible large manufacturers and wholesale druggists, with no more effect than if the potion had been so much water. And that, too, where the same patient, the same day, was stretched out in twenty minutes, perfectly limp and unable to stand, by sixty minims of a more carefully made preparation.

With these facts before us, it is easy to understand both the past and present uncertainty concerning the true status of hemlock as a medicine; and it is plain that whether in experimenting for ourselves, or in judging the results of others, it is an indispensable prerequisite that the individual preparation used in each case shall have been shown by physiological testing to possess full activity. All evidence pro or con concerning hemlock, where this precaution has been omitted, is worthless.

Our real knowledge of the effects and uses of the drug in medicinal doses is of comparatively recent date. To the laboratories of the Germans we are principally indebted for a thorough physiological analysis of the action of hemlock, and mainly to Dr. John Harley, of England, for a bold testing of the effects on man, and for a discriminating use of the remedy in disease.

Conium has thus been shown to belong to the small but exceedingly interesting group of poisons containing the Calabar bean, yellow jasmine, and curare, of which the production of simple motor palsy is the characteristic physiological effect. The seat of this paralyzing influence is the same with conium as with curare; namely, in moderate grades the terminal nerve-endings only, while in full poisoning the motor trunks are also involved, and possibly, in fatal dosing, the spinal cord as well. In medicinal doses, then, hemlock can be considered to cause the paresis simply by interfering in some unknown way with the conducting power of the motor nerve-endings in the muscles. Conium, furthermore, like many other paralyzers, shows a special predilection for certain individual nerves, affecting them earlier and more severely than others. This curious favoritism, although not so strongly marked with hemlock as with other agents, is yet quite distinctly appreciable, and the specially obnoxious nerves in this case are the cranial pairs supplying the muscular apparatus of the eyeball. These nerves always seem to be affected by hemlock slightly in advance of all others, and with somewhat greater intensity.

Upon the sensory nerves it is possible that hemlock may have effect, for its local application is claimed to have relieved the pains of cancer, and a cut surface or exposed nerve brought into contact with the alkaloid is said to lose sensibility. But when the drug is given internally, even in full medicinal dose, there is practically no effect on sensation—certainly nothing at all comparable to the palsy of motion. Thus a patient of mine, while profoundly affected in his motor function, yet showed no failure in the sharpness of the sense of touch when carefully tested with the aesthesiometer. And animals fully poisoned by hemlock, so long as they retain any motor power by which to express it, always give signs of the perception of pain.

Upon the central nervous system conium has little if any primary effect. The intellect is absolutely unimpaired, and such drowsiness as sometimes follows a full dose, is no more than would naturally result from the recumbent posture and muscular rest which the semi-paralysis enforces, especially when, as often happens in therapeutics, the patient has been previously worn out by want of sleep through some painful spasmodic affection which the hemlock temporarily relieves.

A very grave question is, whether conium includes the heart among its victims for paralysis. The weight of evidence has hitherto been that, like curare, it does not; and this supposed immunity of the heart is considered to give conium a great medicinal preference over Calabar bean, which notoriously affects the same organ most profoundly. The grounds for the belief are, in the first place, the fact that patients may be stretched out by hemlock utterly limp and powerless, while yet the pulse is firm and regular and there is no faintness; and in the second place, that in animals killed by the poison the heart will be found to beat many minutes after death. But yet, in the recent case of fatal poisoning in man, paralysis of the heart has, I believe, been inferred by some to have been the mode of death. I am not in position to argue this question, as all my information in regard to the case is the newspaper reports. But I may say that the alleged suddenness of death in this instance does not seem to me to necessarily point to the heart as the seat of the death-blow. For in animals fatally poisoned, as I have myself carefully verified, they will lie awhile flaccid and motionless, breathing slowly but regularly, when all of a sudden they will stop breathing altogether, and with a brief trembling of the limbs will immediately die. But in such case, on quickly open-

ing the chest, there is the heart quietly pumping away, and it will continue to do so, even in mammals, for fifteen minutes or more.

As regards minor disturbances, conium is, for a powerful drug, unusually devoid of effect. There are generally giddiness and nausea, but these symptoms, as I shall shortly explain, are in great part mere consequences of the palsy, and can to a considerable extent be avoided. The bowels are scarcely affected, and there are no disagreeable after-effects whatever.

Hemlock, for a deadly poison, is then wonderfully simple in its influence on the economy. Practically it operates as a pure motor paralyzer, and its modern use in medicine is simply to procure certain degrees of paresis for therapeutic ends. The clinical symptoms attending its use are therefore important to know, but as they have been elsewhere abundantly and graphically described of late, it is unnecessary to take up time with their narration. Suffice it to say that the volatile alkaloid of the drug is very quickly absorbed by an empty stomach, and eliminated with equal speed. Hence, one striking feature of the hemlock action is the quick onset of the symptoms, their rapid increase to full intensity, their short duration at their height, and, after they once begin to abate, their speedy and complete disappearance. Thus in my own person, after taking thirty minims of Squibb's fluid extract, the hemlock influence began to declare itself in ten minutes: in fifteen more it had attained its height: twenty more and the effects were distinctly subsiding, and in another quarter of an hour had wholly disappeared, all but a little flatulent distention and squeamishness of the stomach. And in another hour even these feelings had vanished. Of course with larger doses the effect will last longer, but even after taking a fluid drachm of Squibb's extract, the highest single dose I have personally given, three or at most four hours finds the patient wholly "in statu quo ante" *conium*.

As regards intensity of effect, it is necessary to bear in mind the fact pointed out by Harley, that the degree of palsy is related not so much to the age, weight, or muscular development of the subject as to his habit of motor activity. Thus an active, restless child will bear more hemlock in proportion, and perhaps even absolutely, than an indolent or languid adult. And even the same individual will be affected to a different degree by the same dose, according to whether he take it in the morning when feeling brisk and buoyant, or in the evening when fatigued by a hard day's work. Fullness or emptiness of the stomach also influences the effect of a dose. For the poison is so quickly gotten rid of, after entrance into the blood, that if taken on a full stomach, when *absorption* is perforce comparatively slow, it may get out of the system almost as fast as it gets in. Hence the full dose may never be present in the blood at any one time, and of course the effects will be correspondingly feeble. The bearing of these facts on the therapeutic use of full doses of conium is so obvious as not to need remark.

In kind, the symptoms are mainly those of progressive paralysis, beginning in the ocular muscles. But there is a corollary, so to speak, of this condition of partial palsy, which is so interesting as a matter of physiology, that I must ask pardon for spending a few minutes in its discussion. I refer to the giddiness and nausea which so generally accompany the operation of hemlock. Possibly, after a large dose, some of this disturbance may be primary, but much of it is in all cases purely a consequence of the paresis, and is, I believe, identical in its etiology,

as it plainly is in character, with ordinary sea-sickness. And I think an analysis of the determining causes of the sickness in the two seemingly utterly dissimilar circumstances of hemlock-poisoning and "life on the ocean wave" will be found to throw much light on the etiology of the disorder.

Now I am personally exceedingly susceptible to sea-sickness, but when on the water I have always found that so long as I lie flat and utterly relaxed,—abstain from any movement involving the balance of the body, and either keep the eyes shut or stare fixedly upwards so as not to see the ocean,—then I am wholly free from any disagreeable feeling whatever. But let me violate these conditions in the least, or let the roll of the vessel be so great that a muscular effort is needed to hold the body in place even when flat on the back, and at once I begin to suffer. Here then the determining cause of sickness is either the attempt to balance the body, in whole or part, on a swaying foothold, or the turning the eyes on a field of view where nothing is fixed in position.

Now let us turn to conium. One afternoon, while busily occupied in writing, I took half a drachm of Squibb's fluid extract, and continued my task. No immediate effect following I soon forgot all about the dose. But after about ten minutes, having occasion to recharge my pen with ink, I of course raised my eyes quickly from the manuscript upon which they had been steadily fixed, towards the inkstand, some little distance away. But in so doing I instantly experienced a slight difficulty in accurately sighting that object—the eyes did not strike exactly where they were aimed—and simultaneously a faint but distinct thrill of the peculiar swimming feeling that I know so well as the beginning of sea-sickness, swept through the brain. Plainly the subtle influence of the poison had been creeping over me while absorbed in writing, but could not declare itself by symptom until a quick and decided movement of the already parietic ocular muscles was attempted. Then, however, it was instantly made manifest by the trouble in promptly sighting a given object, and, what is the point, then at once but not till then, was the least giddiness experienced. As the palsy of the ocular muscles advanced, soon the slightest movement of the eyes produced a curious and very disagreeable apparent flickering of the field of view, and was always accompanied by a sudden rush of giddiness. But so long as the eyes were kept motionless, then, as long ago pointed out by Harley, there was no giddiness. For experiment, however, I *did* try the eyes in various ways, seeking to find, among other things, how the focalizing power on near objects was affected: and the consequence was that I quickly became not only very giddy but also decidedly nauseated.—in fact veritably sea-sick, the sensations being the same as those felt at sea. Fearing I should vomit, I got up to cross the room to the wash-stand. But at once the floor seemed to rock and waver and I staggered against a table. Not being conscious, however, of any real weakness of the legs, it immediately struck me that the uncertainty of step was purely because the eyes were playing false as guides for the feet. If so, I argued, walking ought to be steadier with the eyes shut than open. Accordingly, after getting the proper bearings, I shut the eyes, and sure enough found at once that I could now walk straight and steady, and, what was more, without any feeling of giddiness. Securing a basin I repeated the little experiment on the return trip to the desk, and with precisely the same result—giddiness, transient nausea and staggering gait on trying to walk with eyes open,—freedom from all trouble with them shut. This observation I have

further verified with patients taking the drug medicinally. Shortly after this, the paresis, which had hitherto been mainly confined to the ocular muscles, became general, and then I found that, even with eyes shut, any movement involving the balance of the body was attended with a singular uncertainty and falling short of the desired effect, and this was again invariably accompanied by a fresh rush of sea-sick feeling. I accordingly now settled back in my arm-chair, shut my eyes, and for some ten minutes kept absolutely still, with every muscle completely relaxed. The sea-sickness then speedily disappeared, and I became wholly unconscious of any influence of the poison whatsoever. Indeed I had to open my eyes at last and experimentally look about, in order to know whether the enemy was still with me at all or not.

Now comparing the sickness thus occurring in my own person when at sea, and when under the influence of hemlock, we notice that in both cases the exciting cause is either the use of the eyes or the attempt—whether voluntary or forced—to balance the body. And the same very simple and obvious explanation seems to me to apply to all these varied circumstances.

First as regards the part played by the eyesight. *Seeing*, as an intellectual process, is by no means a simple one. Its elements are a perception of the retinal image by the part of the brain endowed with that faculty, and a simultaneous appreciation of the direction of the eyes and of any movement of the same, obtained through the muscular sense and the conscious exercise of motor volition. From these elements then the intellect calculates the actual relations in space of the objects viewed. In other words, *seeing*, in the broad sense of the term, is an intellectual translation of the associated sensory and motor impressions experienced in the use of the eyes. Yet this faculty is not intuitive; it is wholly an acquired art, and it is simply long practice that makes its exercise so easy and certain as to seem automatic. We have, then, in what we call seeing, really a process of reasoning upon the simultaneous presentment of certain impressions through the visual and muscular senses, and conscious exercise of muscular movement. But for this process to develop into an unerring habit, it is obvious that there must be a fixed order of association between the several impressions thus correlated as the data to be reasoned upon. And this again can only occur where there is, as a matter of fact, a fixed relation between position and motion of the eyes themselves and position and motion of the visual image on the plane of the retina. And now how is it, in truth, in this regard? Why exactly such a state of things exists. In the ordinary experience of life there is a definite relation and a very simple one between the motor status respectively of the eye and the visual image. Fixity of the one means fixity of the other, and change of direction of the one is attended by an exactly proportionate shifting of position of the other. This relation then of course determines a definite habit of sensori-motor association in using the eyes, and the one being invariable the other becomes so likewise. The reasoning faculty, then, learning this invariability by experience, accepts it as a final fact, and educating itself wholly on that basis, develops by practice the art of instant and unerring translation of these various correlated perceptions into ideas of actual distance, direction and motion. But suppose now this customary association, just described, be from any cause suddenly broken up, and a different one established. Of course the old rules for interpretation become worse than useless, and the seeing faculty, unable at once to calculate correctly according to the changed condi-

tions, becomes confused and led into error by instinctively falling back into its old habits. And certainly it is not unnatural to imagine that such a state of mental confusion might provoke in sensitive organizations profound functional nervous disorder.

Now then what happens when a landsman looks down on the water from a rolling deck—notoriously the rashest thing he can do? Why exactly such a break-up in the customary sensori-motor association as just supposed, now occurs, for the simple reason that the physical relation between status of eyes and visual image, by which such association is brought about, is now entirely changed. Now though the eyes be fixed in a steady stare, the visual image is *not*, but, in the first place, as a whole it sways up and down and rocks to and fro over the retina, from the motion imparted to eyes, head and body by the rolling of the ship; and in the second place in its several parts it presents nothing but a field of confusedly moving objects. Hence the landsman's brain, accustomed to judge of the lay of the perpendicular and horizontal by the experience of a stable framework to the retinal picture when the eyes are fixed, must now suddenly give up that association of perceptions, and adopt a new one of an oscillating and—if I may be allowed to coin a word—an *inter-wriggling* visual image under the same conditions. Some brains can readily do this, and the co-ordinating centre arranges about the "sea-legs" at once. Others cannot, and with such the least attempt to use the eyesight under the changed conditions produces cerebral confusion, with the symptoms of a swimming in the head, sinking at the stomach, and if circumstances do not change, nausea and vomiting. In other words sea-sickness is the penalty of using the eyes when the customary sensori-motor association involved no longer obtains.

As regards the sickness produced by any effort to balance the body on a rolling deck, the rationale is exactly the same. In keeping our balance, generally, we have muscular action through the co-ordinating centre, guided by information gotten through sight and the muscular sense. Here again, then, we have sensori-motor association, and again a fixed habit of the same springs naturally from the experience of a fixed relation between movement or quiescence of the body on the one hand, and the accompanying state of balance on the other. But on shipboard this relation, again, no longer obtains, for instead of the stable foothold to which the body is accustomed, an irregularly swaying and heaving one is now presented. Hence follows confusion on attempting to make any movement involving bodily balance, and this is again attended by giddiness and nausea.

(To be continued.)

THE MASSACHUSETTS GENERAL HOSPITAL publishes its report for 1874, and announces that sixteen hundred and thirty-nine patients were treated during the year, at an average cost of two dollars and eighteen cents per week for each patient. The average number of patients for the year has been one hundred and forty-nine. Of the total number seven hundred and forty-nine were medical, and the balance surgical cases. The proportion of deaths to the whole number of results was 7.69 per cent. The average time in hospital of paying patients was 2.73 weeks; and that of free patients 5.64 weeks. A new one-story pavilion, called the "Bigelow Pavilion," had at the time of the report nearly reached completion. It was calculated for the accommodation of sixteen patients, and was expected to cost twenty-seven thousand dollars.

CASES OF PARALYSIS ACCOMPANYING STRICTURE OF THE URETHRA.

EXTRACTS FROM A PAPER ON "UNIQUE CASES, MEDICAL AND SURGICAL," READ BEFORE THE N. Y. MED. LIBRARY AND JOURNAL ASSOCIATION, FEB. 17TH, 1875.

By EDWARD BRADLEY, M.D.,

NEW YORK.

THE following case was that of a gentleman who came to me a year ago (after having been exposed to the cold for some time) suffering from acute prostatitis, which had come on after what he had supposed to be an attack of gonorrhœa. His symptoms were slight muco-purulent discharge from the urethra, prostate gland enlarged and tender, incontinence of urine, with great vesical tenesmus, high temperature, with excessive nervous irritability; following later was cystitis with complete paralysis of the bladder, urine loaded with mucus and pus. Kidneys painful, but free from disease; urethra along its whole tract highly sensitive, with the meatus contracted, so that the passage of a 16 French bulb was very difficult; stricture three inches from the meatus defined by a 20 French, about one-half of an inch in length; his nervous prostration was very alarming, and at times he presented symptoms of paralysis of the lower extremities; bowels exceedingly constipated. He continued in this state with slight improvement for nearly two months, and for the first three weeks of his illness I had to draw off his water daily. After a long course of treatment with a long list of remedies internally, combined with washing out the bladder, with medicated solutions varied in their nature, the use of electricity, oxygen gas, etc., and after repeated and earnest solicitation, I succeeded in educating him up to the proper treatment for the permanent relief of all his trouble, which was to divide all his strictures, and make the urethra its normal calibre. His penis measured $3\frac{3}{4}$ inches in circumference. Ether was administered, and I cut the meatus up to the 36 French bulbous instrument, and divided the stricture freely; with Dr. Bismstead's instrument, passed 36 F. into the bladder. The improvement was rapid, marked, and gratifying. He was only confined to his room two days, all symptoms of cystitis rapidly subsided, the swelling in the prostate gland disappeared, and in three months he gained 35 pounds.

This patient was thirty-two years old, and had had gonorrhœa once eight years previous. The second case was that of a gentleman forty-five years of age, who came under my care two months since, with the following history: gonorrhœa three times in ten years, and always accompanied with gonorrhœal rheumatism. Three years ago he had a severe attack, and was on his bed eight months, under the care of homœopaths, who were treating him for all kinds of troubles.

His condition when coming under my care was pitiable in the extreme; he looked like a broken-down old war horse; he was all drawn up, his neck was stiff, muscles all sore and painful: joints puffy, red and painful; pains in the shoulders, back, hips, knees, legs and feet; inability to raise his hands to his head, to lie on his sides, violent spasms of the whole body if he attempted to use any muscle; incontinence of urine, vesical tenesmus, accompanied by a terrific neuralgia of the bladder, etc.; penis constantly moist with a thick creamy pus, with the meatus refusing to admit No. 16 F., and with another tight stricture two and a half inches from the meatus. His penis measured three and one-half inches in circumference. On the 4th of this month I cut the meatus up to 34 F., divided

the stricture also, using Dr. Otis's last cutting and dilating instrument; passed a 34 F. into the bladder freely. The patient, on coming out from under the influence of ether, was able to raise both hands to his head, and the following night he had no difficulty in turning on either side. It is now fifteen days since the operation, and all the swelling has left the joints. He holds his water, and passes a splendid stream. Is sitting up most of the time. Has gained perceptibly in flesh, and feels, as he expresses himself, "like a new man." I can now pass a 33 F. into the bladder, or rather to the bulbo-membranous junction, freely. At this date, May 6th (3 months since the operation), the patient is enjoying good health, has gained in flesh and strength, and is free from all symptoms of rheumatism, and passes water freely.

CASE OF STRICTURE OF THE URETHRA FOLLOWED BY PARALYSIS.

I am indebted to my friend Dr. Chas. E. Simmons for the following interesting case. During the summer of 1873, a gentleman, forty-five years of age, had been complaining for some weeks and had suffered from severe attacks of cholera morbus, when he was suddenly taken with paralysis of both upper and lower extremities. He had been to Long Branch on business, and while there he found himself unable to raise his feet except with difficulty, and while walking on an uneven surface he lost his balance and fell several times. After stumbling through the village he returned to New York, and on arriving here was unable to stand or walk, and was carried home. Dr. S. found him unable to raise himself out of the bed; without muscular control of the extremities or of the head. He had no pain. On questioning him closely he stated that only the day before he felt weakness in the lower extremities. The doctor learned that he had been suffering for twenty years with stricture of the urethra, and on examination found a tight stricture, some three inches from the meatus. The stricture had caused him no particular trouble until within the past fifteen months. From that time the passage had grown very small, and he had passed water with great difficulty; oftentimes he would be three-fourths of an hour emptying the bladder sufficiently to give him relief, and for the past six months he had considerable pain in the lumbar region. His general health had failed rapidly. Upon examining his urethra it was with great difficulty the doctor could introduce the guide to Dr. Gouley's instrument. The doctor's diagnosis was reflex paralysis from stricture, and his prognosis was favorable. The treatment required was removal of the cause. A consulting physician, standing high in the profession, was called in, who pronounced it a case of incipient myelitis, and gave a very unfavorable prognosis, basing his opinion on the fact (as he stated) that there was numbness with partial paralysis of both upper extremities, which, as he remarked, could not be the case in reflex paralysis from stricture. Dr. S. was allowed to go on with the case. He accordingly operated, using Dr. Gouley's instrument, dilating the urethra so as to admit a No. 12 catheter. On removing the instrument two inches of the mucous membrane was torn out. The catheter was introduced, and allowed to remain in several days. Improvement was marked the *next day* after the operation in all the symptoms. In one week all paralysis had disappeared, and in three weeks he had entirely recovered; sailed for Europe, spending three months there, and more than eighteen months have since passed, and he has had no return of his trouble.

A CASE OF CONGENITAL ANAL OCCLUSION OF AN UNUSUAL KIND.

By SUSAN DIMOCK, M.D.,

RESIDENT PHYSICIAN TO THE N. E. HOSPITAL FOR WOMEN AND CHILDREN.

WITH AN OBITUARY OF THE AUTHOR.

By MARY PUTNAM-JACOBI, M.D.,

NEW YORK.

NORA N—, a mulatto child of 11 years, was brought to me in summer for examination, with a view to an operation for incontinence of feces. From the rather imperfect history given by the aunt of the little patient it appeared that at birth the anus was imperforate, with, however, a fistulous opening in the perineum. Within the first week after birth, she was operated upon at the Massachusetts General Hospital by Dr. S. Cabot, with whose kind permission I insert the record of the case. While there "a diagnosis was made of congenital constriction of anus, the passage being pervious, admitting a full-sized probe. A small sponge tent was introduced and retained in place by adhesive strips. Next day a No. XII. bougie was introduced. The opening was then considered large enough, and the patient was discharged. Was readmitted to the Hospital a short time after, on account of the opening being insufficient for the demands of nature, and an operation was now deemed necessary. Upon further examination the case was decided to be one of congenital occlusion of the anus. The place where the true anus should be was marked by a depression and discoloration of the skin, but no opening existed there. One inch in front was the fistulous opening enlarged by Dr. Cabot, through which the feces were discharged. A large silver probe was introduced into the false anus, and carried back as far as the centre of the depression in the direction of the true anus. With the probe for a guide a + incision was made through the skin. The mucous membrane exposed by the incision was then united to the edge of the wound by means of three sutures. A small roll of cloth, well oiled, was introduced into the anus and left for a short time. Feces continued to pass through both openings, when the patient was discharged."

The passage of feces has always been involuntary, and the action of the bowels very irregular, there being sometimes no movement for a week, and at other times as many as twenty-four discharges in a day, while, whether constipated or otherwise, there is no voluntary control over the passage.

Upon examination, I found two openings into the rectum, one (the artificial opening) where the anus is normally found, large enough to admit a goosequill, the other opening through the perineum about three-quarters of an inch in front of the first, and large enough to admit the fourth finger. The child being very nervous, very sensitive, poorly nourished, and slightly feverish (the temperature ranged from 99° F. to 100° during several evenings when it was observed), all operation was deferred, and nourishing diet and out-of-door play recommended during the summer.

In September the patient entered the New England Hospital for Women and Children, and upon the 13th was etherized for thorough examination and such operation as should show itself advisable. I had hoped that the contraction of the artificial anus might be owing to the sphincter, and might be overcome under the influence of ether, in which case a closure of the congenital fistulous opening would remedy the evil, but I

found that the anus remained impervious to the finger, a tense cicatricial ring preventing the least dilatation, while water injected flowed constantly from both openings, showing the entire absence of any sphincter action.

Under these circumstances, the best thing seemed to be the division of the bridge between the two apertures, and I hoped that the one large opening thus formed might become small through cicatrization of the cut surfaces, and that even perhaps later a tolerable sphincter might develop itself through use, as is often the case. I therefore divided the bridge of the perineum without much bleeding, the tissue cutting like cicatrix, and the cut surfaces, which were half an inch in diameter, retracting immediately to a line. The opening thus formed was large enough to admit with ease four fingers, but to my surprise and great pleasure began to contract visibly and take on the folded appearance of a normal anus, so that after the lapse of ten minutes a quart of water being injected was *retained* perfectly, and only ejected with the use of a Sims' speculum. The after history of the case confirmed the most favorable anticipations; the wounded surfaces healed rapidly, there was no fever again, and not the least involuntary defecation. During the first week the bowels were moved by enemata, but afterwards naturally, and by the 21st of September the child was discharged well.

The question naturally arises as to the exact nature of the malformation. It seems to me that we can exclude here the usual atresias of the rectum caused by deficient development of the anal end, which, as embryonic investigations show, starts from the skin and stretches upward toward the rectum. For in such case the sphincter, which shares to some extent in the deficient development, could not have attained so perfect an action in so short a time. Neither can the anterior opening have been of the fistulous nature which is usual in many cases of aproctia, for even after opening the true anus the feces continue to discharge involuntarily through the fistula, which is of course without sphincter. But in our case the anterior opening, the artificial anus, and the divided surfaces all contracted regularly and alike into one round aperture with sphincter action everywhere. Are we not, then, justified in considering this case one of embryonic ulceration and adhesion of the nates near the anal opening, an adhesion complete posteriorly, but leaving anteriorly a canal between the bridge thus formed and the perineum, which canal passed backward into the anus? With this view of the case, the mechanism by which the sphincter was kept powerless for so many years is easily explained. Draw together as illustration the commissures of the mouth, and the action of the orbicularis oris will be so far prevented that at least no liquid can be retained in the mouth. The adherence of the skin at the margin of the anus drew together the sphincter laterally, and rendered its circular action impossible. When this strain was taken off by the division of the bridge, the sphincter naturally assumed its normal action.

THE OBITUARY OF THE AUTHOR.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The accompanying article was entrusted to me for publication by Dr. Susan Dimock, just before her departure for Europe in the ill-fated *Schiller*. I had not yet fulfilled her commission when the news of her death reached us. This news is terrible, not only to Dr. Dimock's personal friends, but to that still wider circle who had recognized her fine talents, and

her great value therefore in the difficult enterprise of hewing out for woman an equal place in the medical profession. Dr. Dimock graduated with honors at Zurich after the prescribed four years' term of study. Her thesis was written on the cases of puerperal fever she had had an opportunity of observing in the wards of the hospital. She has been practising medicine in Boston a little over two years, but in this short time has already won for herself a deserved reputation among some of the best surgeons in the city. As resident physician at the New England Hospital, she has already performed many important surgical operations. A case of vesico-vaginal fistula was published in your columns some months ago. The brief note that I have again the honor of sending to you relates a successful operation on a child, on whom so distinguished a surgeon as Dr. Cabot had already operated in vain. Last fall, while on a visit to Boston, Dr. Dimock showed me the photographs of another hospital patient, from whose neck she had removed a large sarcomatous tumor. The operation had been performed in the presence of the students of the hospital and of Dr. Cabot, consulting surgeon. After reading the record of the case, I mentioned a precisely similar operation that I had seen performed by Richet in the Clinique at Paris, and the lecture, in which he described the great difficulties of removing a tumor deeply imbedded in so dangerous a locality. The Professor had seemed not a little proud of his own success in coping with these difficulties, and had taken care that a numerous auditorium should witness *his* triumph. At this Dr. Dimock laughed, and said, "I was asked why I had issued no invitations, but I had forgotten all about them." She added, "Indeed I have too little personal ambition to care who sees, when I am once assured my work is well done." The remark was characteristic of the modesty and simplicity that distinguished the young surgeon. She was as fresh and girlish as if such qualities had never been pronounced by competent authorities to be incompatible with medical attainments. She had indeed a certain flower-like beauty, a softness and elegance of appearance and manner such as is abundantly lacking in the women most eager to denounce surgical accomplishments as outrageously unfeminine. I have wondered whether she did not resemble Angelica Kaufman. Underneath this softness, however, lay a decision of purpose, a Puritan austerity of character, that made itself felt, though unseen. "She ruled her hospital like a little Napoleon," said a lady who had been there under her care. The ideal steadfastness, which is only possible in characters of this kind, was shown to me at my first interview with her, when she came—a girl scarcely out of her teens—to Paris, on her way to Zurich. We urged her to spend a few days in the capital, for the sake of the recreation to which American students usually consider themselves entitled before they settle down to their studies. Miss Dimock alone refused, for the reason, which she gave with the utmost frankness, that she had been obliged to borrow money in order to prosecute her studies, and should not feel justified in spending a cent of it for amusement or sight-seeing. She put forward all amusements into the future, until she should have won her university degree, and should have fulfilled a pledge of hospital service in Boston. Towards this horrible voyage of April, 1875, converged the pleasurable anticipations of nearly seven years. Among all the bright lives that have been engulfed in this dreadful shipwreck, none is more valuable than hers. Perhaps no woman's life of equal social value has met this tragic fate since the body of Margaret Fuller

was washed ashore on the western coast of the Atlantic. For the success of the social enterprise of securing for women a place in the medical profession finally depends upon but one condition, the demonstration, namely, by repeated indubitable practical evidence, of their real fitness for each branch of its work. None are fitted for all, and both the surgical talents and surgical training of Dr. Dimock are certainly, at the present date, exceptional among women. It is on this account that her loss is literally irreparable, for at this moment there seems to be no one to take her place. Many battles have been lost from such a cause. But although ours be ultimately won, we would not, if we could, grieve less loyally for this girl, so brilliant and so gentle, so single of purpose, and so wide of aim, whose life has been thus ruthlessly uprooted and thrown upon the waves at the very moment it touched upon fruition.

MARY PUTNAM-JACOBI.

CHLOROFORM AND NITRITE OF AMYL.

By F. A. BURRALL, M.D.,

OF NEW YORK.

In the *Medical Times and Gazette* of Dec. 12th, 1874, is an account of some experiments by Dr. Schüller, made for the purpose of determining the action of certain drugs upon the vessels of the pia mater. It is stated that "after the inhalation of chloroform the veins and arteries of the pia mater at first contract, but they very soon become relaxed, and considerable venous congestion follows. Dr. Schüller has made the interesting observation that nitrite of amyl not only quickly removes the effects of chloroform on the vessels of the pia mater, but in cases of advanced narcotism from the latter drug, it rapidly relieves the dyspnea and labored respiration, and renews the strength of the pulse, while at the same time it restores the animal's reflex excitability in an astonishingly short space of time." The author of the communication to the *Medical Times and Gazette* then adds: "We are not aware whether nitrite of amyl has been tried in cases of danger from chloroform in man, but the above observation is worth remembering by those engaged in its administration, and it may possibly be the means of saving valuable lives."

Those who have struggled with sturdy patients through the maudlin inebriety which usually precedes the anesthesia produced by ether, would fain prefer the brief excitement and calm slumber which are induced by chloroform. But chloroform has fallen into disfavor since so many deaths have attended its use. Children and parturient women have been found to bear it exceptionally well, and it is regarded as a comparatively safe anæsthetic for the field. But the mortality among others has been, as compared with similar agents, very large. Hence the inconveniences incident to the employment of ether do not counterbalance the risks of chloroform, and ether is preferred for general use. Perhaps Dr. Schüller's experiments will enlarge the field for the safe administration of chloroform.

Whether nitrite of amyl has been used to avert the dangers from chloroform in man I do not know, but it has long seemed to me, from *à priori* reasoning, to be indicated under such circumstances, and in a short paper on the nitrite of amyl which I sent to the *New York Medical Gazette* of June 11th, 1870, I recommended its use in the following words: "It would seem worthy of a trial in the threatened syncope from chloroform; since the inhalation of but a few drops is followed

by marked acceleration of the heart and flushing of the face." In my own practice I have never had an opportunity of making the trial, but with this stronger light of recent investigations should consider it more than ever a duty to do so.

Evidently, with these experiments of Dr. Schüller before us, science now demands that *whenever chloroform is administered, the nitrite of amyl should be at hand as one of the agents to be employed in case of impending danger.*

Progress of Medical Science.

THE THERAPEUTIC VALUE OF THE BALSAM COPAIBA.—Dr. Hall, Surgeon in the Army Medical Department, calls the attention of the profession to the value of the balsam in other cases than in those in which it is generally employed. After referring to the value of the balsam as a diuretic, as set forth by Dr. Dixon in *The Practitioner* for February last, he says that we know it is given almost exclusively in gonorrhœa, so much so that persons for whom it is prescribed are usually suspected of suffering from that disease. The following statements, however, show that the doctor believes it to be a valuable remedy in other cases. In inflammations of the eye, he reports an instance of severe iritis in a soldier, whom he saw in consultation with the regimental surgeon. He found the right eye highly inflamed, the whole of the anterior chamber being filled with pus. Vision was entirely lost. The man had suffered from syphilis, and had been treated with various remedies, but with no beneficial result. He thought that the eye was destroyed beyond redemption, but suggested a trial of the drug, as he had seen the good effects of the balsam before, in cases of iritis. Two drachms, in mucilage, were therefore ordered three times a day. Two days after, the pain had subsided, and daily the pus could be seen to be gradually disappearing. In ten days he could see the length of the ward, and after twenty days the eye was quite well. An account of the case is given in the *Indian Medical Gazette* for September, 1872, by Dr. Tothill, who wrote that the balsam had acted like a charm, and all who saw the man were convinced that but for it the eye would have been destroyed. For some years past, in India, Dr. Hall has been in the habit of giving it in all cases of iritis and scleritis, and he found it far preferable to turpentine, as it does not produce strangury. The pain of scleritis he has often found to subside, and the inflammation disappear after four or five large doses of the balsam. In 1872 he had at one time under his care more than thirty children suffering from purulent ophthalmia, and he treated them all by simply painting the lower eyelids, upper part of the cheeks and the temples, with the pure balsam, and they all quickly recovered without damage to the eyes.

In threatened mammary abscess, Mr. Hall thinks the drug may often be employed with success. He attended at the confinement of a delicate woman, who had previously suffered from a mammary abscess, which had been treated by leeches and an antiphlogistic regimen.

In the confinement to which he referred the other breast became inflamed, and she felt convinced, judging from her former sensations, that an abscess would form. The breast was hard and painful, and she was obliged to give up nursing her infant. He ordered a full diet, with porter and port wine; and every morning, for a week, painted the whole surface of the breast with the pure balsam, covering it with flannel

and oiled silk. Whether the copaiba prevented the formation of the abscess he is not willing to affirm, but no suppuration occurred. As a rule, he thinks that it is in the weak and anæmic that these abscesses form, and probably the nourishing diet did her most good. But he has employed the balsam in other inflammations, locally, with advantage.

Mr. Hall refers to its use in chronic rheumatism, especially in old people, and he also mentions its beneficial effects to some skin diseases and in its local application to old indolent ulcers of the legs.—*The Practitioner*, April, 1875.

BICARBONATE OF SODA IN THE TREATMENT OF TOOTHACHE.—Dr. Duckworth, of St. Bartholomew's Hospital, has related a case of severe toothache which was almost immediately relieved by the use of bicarbonate of soda, after various other remedies had failed. The patient was a boy, suffering from caries of one of the molar teeth. Chloroform was rubbed outside the cheek, and some on cotton wool was placed inside the auditory meatus. These means failing, a plug of cotton saturated with chloroform was inserted in the cavity of the tooth. This was also unsuccessful. Next, pure carbolic acid on cotton was placed in the cavity, but no improvement followed, and chloroform was then again tried without success. As a last resource, a solution of bicarbonate of soda, of a strength of about half a drachm to an ounce of water, was tried with the above happy result. He says that a mouthful of cold water will sometimes relieve the pain of toothache, but he cannot remember whether he tried that plan before using the solution of soda. It struck him as noteworthy, that a feeble alkaline solution should produce such a decided effect after the application to the sensitive dentine of a powerful agent like carbolic acid. If the toothache be excited by unhealthy (acid) saliva, or buccal secretion, it becomes intelligible that an alkaline solution should rectify this. He suggests that it would be well to test the reaction of the saliva and of the buccal mucus in cases of toothache, with a view to ascertain their possible influence upon the surfaces of carious teeth, and he believes that the saliva will be found to give an acid reaction more often than is generally believed or taught. He also suggests the use of a warm solution of the bicarbonate, so as to be more sure of the effect of the remedy employed.—*The Practitioner*, April, 1875.

EXPERIMENTS ON THE EFFECTS PRODUCED BY LIGATION OF THE DUCTUS CHOLEDOCHUS, AND ON THE CONDITION OF THE BLOOD IN MALIGNANT ICTERUS.—It is stated in a note to the French *Académie des Sciences*, that MM. Feltz and Ritter have ligatured this duct in nine instances, and have shown by their experiments that the blood absorbs the biliary salts and retains them for a longer or shorter time, and is in consequence more or less altered. The blood globules become diffuent; the hemaglobin transudes and even crystallizes; the fatty granules, in considerable quantity, and the crystals of cholesterine, accumulate in the serum. This alteration in the blood varies with the quantity of biliary acids which are present. The jaundiced appearance does not depend on the biliary salts or their products, but on the retention of the coloring matter.

The absorption of biliary salts has a limit, for the biliary secretion itself diminishes when once the dilatation of the biliary passages is considerable, and when the epithelium of the passages undergoes fatty degeneration, as it does under the influence of the great increase in the intra-canalicular pressure.

This modification of the secretion is said to explain the rarity of nervous or hemorrhagic complications in icterus due to retention. In this respect there is a great difference between icterus due to alcoholism or the icterus of hyper-secretion of bile. In a single instance the experimenters succeeded by artificial retention of the bile, in producing the grave symptoms of malignant icterus, and in this case they found that the blood contained a quantity of biliary salts, about or a little exceeding one per cent. So far as the clinical value of these experiments is concerned, it is thought that a comparison between real diseases characterized by icterus and those produced artificially, shows that the severe symptoms are in a great measure due to the absorption of the biliary salts into the blood.

As a general conclusion, they believe that intoxication of the blood is the characteristic of all so called *bilious* conditions, whatever they are. The morphological and chemical changes in the blood are therefore the principal lesions of such diseases.—*La Tribune Méd.*, April 18, 1875.

RECENT VIEWS ON THE MONOBROMIDE OF CAMPHOR.—Dr. Lawson, of London, who contributed an article to the *Practitioner* some months ago on Camphor and its monobromide, found at that time that the conclusions he had reached were, in a measure, confirmatory of those recorded by Dr. Bourneville, of Paris. More recently, however, he has made a long series of experiments on various animals, the results showing that the drug possesses, as shown by Bourneville, marked hypnotic and calmative properties, while on the other hand, it has many objectionable features which stand in the way of its employment in practical medicine. These latter are principally its insolubility and the gastric irritation which is apt to follow its use. Dr. L. states that a glance at the substances which are accepted as indubitably possessing the therapeutic features claimed for this medicine, will show how far it falls short of the potency and fitness possessed by the former. Opium, chloral, cannabis indica, bromide of potassium, belladonna, hyoscyamus, conium, ergot of rye, valerian, assafoetida, and all diffusible stimulants possess many of the medicinal functions ascribed to the new drug.

The author states that he will not deny that by virtue of its hypnotic properties monobromide of camphor may, when administered in sufficient quantities, produce sleep in insomnia, subdue emotional, sensory, and motor irritations in hysteria, control convulsions, and even overcome the excitement of delirium tremens, yet it is evident that the drug cannot operate with the certainty and safety of other well known remedies. Monobromide of camphor is an agent distinguished on the one hand by the absence of any independent or special therapeutic value, and on the other by the presence of several faults from which many analogous and more potent substances are altogether exempt.

M. Trasbot, of Alfort, has been even more unsuccessful in obtaining the results claimed by M. Bourneville. He observes that neither somnolence, slackening of the pulse, nor diminution of the temperature followed its employment, but the patient had attacks somewhat resembling tetanic convulsions.

M. Paul has tried it in one case of convulsive hysteria; M. Dujardin-Beaumetz in thirty cases of hysteria, epilepsy, or troubles of the genito-urinary organs. The results were unsatisfactory in epilepsy; in hysteria the change was slight; in spermatorrhoea, however, the drug was very effectual, but the action was due rather to the camphor than to its bromide. M. Gubler employed

it unsuccessfully in four cases of hysterical vomiting. The patients complained of heat over the epigastrium, and they had fever with general excitement, but the vomiting continued.—*Practitioner*, April, 1875, and *Trib. Méd.*, April 18, 1875.

NITRITE OF AMYL IN EPILEPSY.—We are indebted to Dr. James H. McBride, of the Hospital for the Insane at Oshkosh, Wisconsin, for some valuable observations on the action and use of nitrite of amyl in epilepsy. It is stated that epilepsy depends upon a condition of cerebral anaemia induced by spasmodic contraction of the arteries of the brain. The action of amyl is directly antagonistic to this. It causes distension of the cerebral blood-vessels and congestion of the brain. The action of the drug was very prettily demonstrated in some experiments which were made by McBride and Kempster. A portion of the skull of a live full-grown rabbit was removed, so as to expose a considerable surface of the cerebral membrane. After the effects of the anæsthetic used during the operation had passed away, the nitrite of amyl was administered, and its action on the brain observed through the aperture in the cranium, with the aid of a strong lens. In a few moments the vessels of the pia mater became engorged with blood, so that vessels could be seen distinctly which were before invisible to the naked eye; the brain became dark and congested, and so swollen as to protrude through the artificial opening. At the same time the external vessels of the ear were distended with blood. The inhalation being stopped, all these symptoms soon disappeared, and returned as soon as the amyl was administered again. A second experiment of like character yielded precisely the same results.

McBride details several instances in which the nitrite of amyl has been employed under his observation for the treatment of epilepsy. The results were remarkably favorable. The effect of the remedy was immediate, and its efficacy in warding off imminent attacks was particularly striking. The good effect does not appear to have remained, however, after discontinuance of the remedy. The mode of administration consists in dropping ten to fifteen drops upon a piece of cotton, and the vapor is then inhaled.

Particularly favorable results are promised in those cases where the aura is very decidedly marked. A caution is given against employing the nitrite of amyl in certain spurious forms of epilepsy, convulsions which are dependent upon congestions of the brain, where the drug might have a decidedly pernicious effect, through simply aggravating the existing disturbance.—*Chicago Journal of Nervous and Mental Diseases*, April, 1875.

PHYSIOLOGICAL ACTION OF THEBAIN.—Dr. J. Ott reports some experiments made with the object of determining the action of thebain—one of the most deadly toxicants amongst the alkaloids of opium—upon the animal economy. The results of his investigations are given in the following *résumé*:

"1. Thebain is a tetanoid agent, and pigeons have no special immunity against it.

"2. The tetanus is not cerebral, but spinal in origin.

"3. The motor and sensory nerves and the striated muscles are not affected by it.

"4. It increases the pulse and blood-pressure by an action on the vaso-motor centre and the heart itself.

"5. The reflex action of the depressor nerve is in no way interfered with."—*Bost. Med. and Surg. Jour.*, April 8, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

W.M. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, May 22, 1875.

WHAT CONSTITUTES ADVERTISING?

WE would be disheartened in so frequently referring to newspaper advertising if we were not interested in the solution of the question by the profession. If it is not wrong to advertise, to publish our medical papers in the daily press, and to be heralded to the gaping multitude as leaders in medical thought, as expounders of new doctrines and the like, then we might as well all turn quacks at once. It is pretty certain that the line must be drawn somewhere. Every little while the necessity for some conclusion in regard to this matter is forced upon us by some of the professional advertisers.

We hear a great deal of talk by the societies about the dignity of the profession and the enforcement of the Code, but when any positive decision is required, when any discipline is needed, there is a strange and unaccountable silence. Most, if not all, of the progressive gentlemen who believe it is right to advertise as they do are members of respectable societies, and many of them not only hold official positions therein, but are the very priests at the altar, members of the committee of ethics, the least of whose duty it should be to show an example to some of those who have lesser responsibilities. The various county societies pretend to interpret the Code, and yet, except in the case of some poor, obscure, and friendless transgressor, when do they ever discharge their obligations to the profession?

In view of the acknowledged necessity of educating the public in medical matters, a very interesting question comes up—how can this be done with propriety, how can the profession accomplish good in this direction without danger of violations of the Code? The Kings County Medical Society has attempted a solution of the difficulty, in the organization of a department of public instruction, whose duty it shall be to select and publish such material as shall be of benefit to the public. The details of their plan of

operation may be open to many objections, but the principle of censorship sought to be established by this committee, is a good one, and worthy of all imitation. This takes the responsibility of the publication of medical papers out of the hands of the authors, and is, in our opinion, one of the principal means of securing a desirable end.

The time has passed to declare that it is wrong to publish any medical matter in the daily papers. There is some information which we can impart and to which the public are entitled, and it is just as much our duty to furnish such information, as it is to discharge any other professional obligation. These duties are thus defined by the Code of Medical Ethics:

“As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession, as on subjects of medical police, public hygiene, and legal medicine. It is their province to enlighten the public in regard to quarantine regulations—the location, arrangement, and dietaries of hospitals, asylums, schools, prisons, and similar institutions—in relation to the medical police of towns, or drainage, ventilation, etc.—and in regard to measures for the prevention of epidemic and contagious diseases; and when pestilence prevails, it is their duty to face the danger and to continue their labors for the alleviation of the suffering, even to the jeopardy of their own lives.”

In following out the letter and spirit of this injunction, it is clearly seen that an abundance of latitude is given for not only benefiting the public directly, but for elevating the profession indirectly. Herein are stated all the subjects concerning which the public really have any concern; and information about any one of them does not necessarily imply the possession of any knowledge not shared by the profession at large. On these matters we speak as a profession, but not as individuals. The greatest credit which any expounder of medical truth should claim of the public he instructs, is that of being well grounded in the fundamental truths of his art; if he goes beyond this and claims to possess a special knowledge of the subject for which, as an individual, he expects to benefit, he at once becomes a quack. And here we think the line should be drawn between the public benefactor and the professional advertiser.

Our duties to the public refer entirely to the prevention of disease, and not to its cure. A general knowledge is sufficient to appreciate the truths of the former, but a special education is absolutely necessary to understand the latter. On sanitary matters the general public is well calculated to judge, and is prepared to receive instruction. For instance, in matters of drainage, cleanliness, ventilation, and other hygienic measures, they are well enough informed to appreciate what is new and useful, and to apply the truths accord-

ingly. In so far as pure sanitary science is concerned, the profession may be considered as speaking to a well educated, appreciative, and discriminative audience. On special professional subjects, however, the case is so entirely different as to admit of no comparison whatever. The public need no such information, are not prepared to receive it, and have no possible means of judging of its value. Generally what is really worth nothing as a contribution to medical science proper is believed to be of the greatest value by outsiders. The author of such a paper generally appears as a great expounder of some new doctrine, and not unfrequently conveys the impression that he is the centre around which the whole science of medicine revolves. The more abstruse his statements, and the more unintelligible he makes himself by the use of technical terms, the greater idea the people have of his profundity. And how is the public benefited by papers on pathological anatomy, the origin of the nerve centres, and the like? There is no question in the mind of every professional man what is the motive for the publication of such material. It is a flimsy excuse for the transgressors of the Code to plead a desire to educate the masses. If they are guided by their consciences to do such a thing, the Code very distinctly points out the way for them. There is enough of accepted truth in medicine, a knowledge of which is not only necessary but useful to the public, to employ all the time and energies of the ambitious educators. But this is not the way to be benefited and get practice. It is necessary to make some discovery, and every little while startle the public with the idea that the medical profession, and science in general, could do nothing without them. If such persons can prove to the public that their professional brethren know nothing and that they know everything, it is sufficient to insure a large business. This is the only motive for this kind of advertising, and it is transparent enough for the most stupid observer. As we have before remarked, it is the duty of the different societies to settle where the boundary line should be. It is very easy to enforce discipline if they dare do it. The Medical Society of the County has members who openly, persistently, and defiantly advertise, and its obvious duty is to punish the wrong-doers. The Medicohistorical Society has a duty to perform in this matter in erasing from the list of honorable medical men the names of these advertisers. Whether this association dare do this is a very serious question to propound, notwithstanding at the head of their list of names are extracts of the Code bearing particularly upon the sin of advertising. If this cannot be done with the *Medical Register* it must cease to be authority for the profession at large. We wait with no little anxiety to see if, in the next volume of this annual, so soon to appear, the society is ready to back a principle at all hazards, or disgrace itself by trimming to an expediency.

SECOND-HANDED PAPERS BEFORE SOCIETIES.

DURING the recent meeting of the American Medical

Association, the question concerning second-handed papers came up for a decision. It has been the fashion from time immemorial for certain authors of papers to peddle them from one society meeting to another, and make all the capital they can before strange audiences. Not unfrequently these articles have been read over five or six different times as original ones, and lastly are presented before one of the sections of the Association, and appear in the transactions. The practice has indeed been carried on to such an extent that it has been looked upon as one of the recognized means of cheap advertising. Such papers frequently make their first appearance before some county society, and in a large city go the rounds of all the greater and lesser associations, until the annual meeting of the State Society, when they are read again, and if by that time they are not published, the chances are good for some of the sections referred to. The same thing is done with some remarkable case, the relator presenting it before every association of which he is a member, until it is known by all society-goers as a very old story.

The committee who have had charge of the selection of papers to be read before the sections have taken a very commendable stand in this matter by ruling out everything which is not entirely new. In spite, however, of their determination to be radical in this respect, it seemed impossible to prevent the presentation of some papers which were not only read before, but abstracts of which have already been widely published. Now, however, that the proper initiation has been taken, we shall hope for better things in the future. Let the other societies follow the example.

THE SUIT FOR MALPRACTICE.

THE suit for damages against the N. Y. Eye Infirmary, and Dr. Derby, one of the surgeons of that institution, has terminated by the acquittal of the defendants. This was a case in which an attempt was made to show carelessness on the part of the surgeon in using a brush not properly cleansed, for the application of nitrate of silver to the eye of the plaintiff. It was claimed that the said brush contained pus from an infected eye, and that in consequence a destructive inflammation of both the eyes of the plaintiff ensued. The defence claimed that the brush was thoroughly cleansed, that every ordinary precaution was taken to guard against bad results, and that the patient not only voluntarily absented himself from the institution, but placed himself under the care of his family physician, who, for some reason not explained, departed from the usually accepted treatment of such cases by applying hop poultices.

A number of distinguished oculists testified on behalf of the defendants, and the jury had no hesitation in bringing in a verdict.

The result was as was expected, and reflects credit upon the trustees of the institution for care in its man-

agement, while it detracts nothing from the well-known skill of the surgeon who had the charge of the case in question.

MEDICAL LEGISLATION IN TENNESSEE.

At a recent meeting of the Knox County Medical Society, a committee which was appointed to make suggestions regarding a bill for the regulation of the practice of medicine, pending before the Legislature of Tennessee, offered the following :

"That the less the medical profession, as a profession, has to do in identifying itself with legislative enactments, and the more its members are left each to be his own cicerone before the public, and answerable to public opinion and the laws as they are for any damage he may commit, the more respect will be given to the whole profession."

The following resolution, after considerable discussion, was also adopted :

"Resolved, That the secretary be instructed to request Senator Ellis to place a clause in his bill, making it a misdemeanor for any one to claim to have graduated in a Medical College, or taken the degree of M.D., when such is not the case."

This is an evidence of the growth of medical sentiment in regard to special legislation which is certainly very encouraging.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

REPORT OF SECTIONS.

SECTION ON PRACTICAL MEDICINE, PHYSIOLOGY, AND MATERIA MEDICA.

DR. AUSTIN FLINT, of New York, Chairman.

DR. ——— BARTLETT, of Wisconsin, Secretary.

TUESDAY, MAY 4—FIRST DAY.

The first paper read before the Section was a report by Dr. N. S. DAVIS, of Chicago, upon

THE NECESSITY OF CO-INCIDENT CLINICAL AND METEOROLOGICAL RECORDS IN THE STUDY OF METEOROLOGICAL INFLUENCES AND ATMOSPHERIC CONDITIONS IN THE DEVELOPMENT OF BOWEL AFFECTIONS OF CHILDREN.

This report was made in conformity to a suggestion offered at the last meeting of the Association, with reference to pursuing definite lines of investigation for attaining definite data concerning the beginning of diseases.

The author claimed that when we come to study this question of etiology, we are met with difficulties not easily overcome, and chief among these is the absence of continuous and carefully recorded facts with regard to appreciable conditions or qualities of atmosphere, and the date of the initial symptoms of the disease. We have at our command meteorological observations such as relate to the extremes of heat and cold, velocity of the winds, quantity of ozone present in the atmosphere, etc., but, on the other hand, the data with

reference to the commencement of disease are almost entirely absent.

To study satisfactorily the cause of acute diseases, there is need of three distinct series of observations and records, made simultaneously and continued through a series of years. One of these should consist of a complete register of atmospherical conditions, including electricity and ozone.

Another is observations made by active practitioners of medicine with reference to the commencement of the active symptoms of acute diseases coming under their observation, and the date of recurrence, when such occurs.

The third series of observations should be microscopical, and made with reference to the atmosphere and liquids taken into the body.

If this series of observations can be made, there will be a basis established for observation and deduction, and we shall be enabled to trace the relation between attacks of acute diseases and their causes.

The report was accepted, and the resolution, recommending the renewal of the special committee whose duty it shall be to prosecute the work and report progress at the next meeting of the Association, was adopted.

A lengthy discussion followed, which was participated in by Drs. Edgar, of St. Louis; Wood, of Philadelphia; Davis, of Chicago; Woodruff, of Indiana; Bartholow, of Cincinnati; Gaillard, of Louisville; Ulrich, of Pa.; and Johnson, of Missouri.

The report was referred to the Committee on Publication.

The second paper was read by Dr. CLARK, of Boston, on

THE SIGNIFICANCE OF DOSES IN MEDICINE; OR, DOSES, THEIR PHYSIOLOGICAL AND THERAPEUTICAL IMPORT.

Of doses there are the single, the continued, the frequent, and the toxicological. The first and the last are those given in treatises upon materia medica.

The continued and frequent doses were specially considered.

The continued dose is the administration of a drug in such a manner that elimination of one dose does not take place completely before the absorption of the following dose is commenced. In this manner the blood is kept constantly charged with the drug.

The single dose may charge the blood with the drug, but elimination is permitted to take place before absorption of the second dose is begun. The physiological and therapeutical difference between these doses is important. Ammonia, gallic acid, bromide of potassium, alcohol, etc., were referred to as remedies readily absorbed, and rapidly eliminated; and if the physician desires to obtain the best effect from those drugs, or a prolonged effect, he must give them in such a manner that elimination of one dose will not be completed before absorption of another will have begun.

The man who takes an eye-opener in the morning, wine for dinner, a digester for supper, and a night-cap for the night, is constantly under the influence of alcohol.

The frequent dose is giving of medicine so as to impart to the organism some one or more of its actions in rapid succession. For instance, aconite may be given in five-drop doses of the tincture, but one-half-drop doses repeated every half hour for ten times, or drop doses repeated every hour for five hours, have a far different physiological and therapeutical effect than when the entire five drops of the drug are given at once.

The special point in the paper insisted upon by the author was, that continuation of doses was not necessarily a continuous dose; but in order to administer a continuous dose the ratio between absorption and elimination must always be kept in mind.

The paper gave rise to considerable discussion and complimentary remarks. It was referred to the Committee on Publication.

WEDNESDAY, MAY 5—SECOND DAY.

BIOMETRY IN ITS RELATION TO THE PRACTICE OF MEDICINE.

The first paper of to-day's session was read upon the above subject by Dr. Moreau Morris, of New York.

The paper will be published in full in a subsequent number of this journal.

It was referred to the Committee on Publication.

DR. BARTHOLOW, of Cincinnati, presented some practical observations upon

EXOPHTHALMIC GOITRE AND ITS TREATMENT.

The essential features of the disease were considered, the relation which they sustained to each other, with reference to priority of development, and the fact that in some cases all the symptoms may be absent except the excessive action of the heart and lack of co-ordination of the upper eyelid, first described by De Graffe.

All the cases which he reported were treated by galvanization of the pneumogastric and sympathetic nerves, and with good success.

DR. DAVIS, of Chicago, mentioned the fact that under his observation a few cases had done remarkably well upon a rather protracted treatment, consisting of carefully regulating the diet, careful exercise in the open air daily, and the internal use of the *co. syr.* of the hypophosphites, taken after meals, and digitalis pushed at first sufficient to produce positive slowing of the pulse, and subsequently to keep the patient under an appreciable degree of influence without getting the cumulative effects of the drug.

If tonics are used they should be selected with reference to avoiding excitation of the nervous system; and if any other form of tonic is used it should be associated with some sedative which will answer the purpose of keeping down the peculiar excitability which may be produced by the tonic used. The paper was further discussed by Drs. Kert, Flint, Oetrloney, and then referred to Committee on Publication.

The report of the Chairman of the Section, read before the Association in general session, was next taken up and referred to the Committee on Publication.

CYSTIC DEGENERATION OF THE KIDNEYS

Was the title of the next paper, which was read by Dr. Oetrloney, of Louisville.

It was referred to the Committee on Publication.

THURSDAY, MAY 6—THIRD DAY.

TREATMENT OF ACUTE PNEUMONIA.

DR. IRWIN, of Mansfield, O., read a paper upon the above subject, in which he set forth his views relative to the action of alcohol in the treatment of pneumonia, and reported 147 cases. His average attendance upon the patients was five days. *Not a single death occurred.*

His statements were as follows: Alcohol is as distinctly specific in the treatment of acute pneumonia as quinine is in the treatment of intermittent fever. There are two processes constantly going on in the sys-

tem—the constructive and the destructive. If destructive changes are retarded the demand for constructive assimilation will be proportionately diminished. If nutrition is deprived by one-half of its normal supply of oxygen by impermeability of the respiratory membrane, and if the process of disintegration of tissue can be proportionately diminished, the supply of oxygen will still be equal to the demand, hence asphyxia cannot result. His position was that death occurs in pneumonia by asphyxia, dependent upon an impermeable condition of the respiratory membrane. Oxygen is prevented from being admitted, and if now disintegration of tissue, which results in the production of carbonic acid gas, can be retarded sufficiently to diminish the demand for oxygen in the same proportion, it is the thing desired and indicated. Alcohol is undoubtedly an agent which possesses such power, hence its applicability in the treatment of this disease, which so materially interferes with the respiratory function, therefore the proper ratio between the constructive and destructive processes which exists in the system when it is in the normal condition.

DR. EASTMAN, of Indiana, thought that there should have been more evidence presented in the paper, such as derived by physical exploration of the chest, than was given, in order that the members of the Section might have been prepared to judge with regard to the reliability of diagnosis.

DR. DAVIS, of Chicago, regarded the diagnosis as being exceedingly suspicious, taken in connection with the fact that not a single death occurred out of the 147 cases reported.

DR. YANDELL, of Louisville, remarked that the success obtained in the treatment of these 147 cases surpassed all his powers of belief.

DR. FLINT, of New York, sustained the criticisms relative to accuracy in diagnosis.

DR. IRWIN remarked that the exact symptoms of a certain stage of the disease were not necessary to be considered according to his theory. The theory which he brought forward was that the impediment in the respiratory membrane is the difficulty which is at the bottom of all the trouble, and it does not matter just exactly as to the stage of the disease so that that condition still obtains. He remarked that he was not at all surprised that the profession is altogether astounded with the results of the treatment. With regard to the criticism upon correctness of diagnosis, mistakes are hardly presumable in these days, where a man sees that number of cases, and it is nothing unreasonable to suppose that an active practitioner may see such a number of cases within twelve years.

The paper was referred back to the author for further investigation.

NOTICE OF THE BIOPLASSON DOCTRINE—BY DR. L. ELSBERG, OF NEW YORK.

In this paper DR. ELSBERG brought to the notice of the Section a new biological doctrine, intended to take the place of the cell doctrine. He explained the cell theory as represented by Virchow and others, and showed that the ideas originally connected therewith had undergone a gradual change with the advance of microscopical and histological knowledge. He showed that the word "cell," to designate the organic form-clement, had long been a misnomer, and claimed that, since the discoveries in histology and pathology of Dr. Charles Heitzmann, formerly of Vienna, now of New York, it would be not only erroneous in fact, but also misleading and mischievous in practical consequences, to continue to adhere to the cell doctrine. He exhibited and explained half a dozen diagrams.

showing first the structure of the lowest form of animal life, the so-called amœba, found in organic infusions, in salt and fresh water, etc., and then the structure of colorless blood-corpuscles of man, as seen upon the heated stage of the microscope under varying circumstances, and with a magnifying power of from 800 to 1,000 diameters. He took up the examination of a number of tissues, such as cartilage, muscle, nerve, and epithelial tissue, and showed that, throughout, there existed, instead of separate isolated cells, accumulations of living matter connected by a network of living matter. Just as the amœba, which has been supposed to consist of a homogeneous structureless lump of jelly-like living matter, called protoplasm, containing granules supposed to be foreign ingredients, consists of a mass of living matter arranged into a network, the points of intersection of the threads of which are thickened and constitute granules, and in the meshes of which is contained the non-contractile not-living fluid,—so the whole animal body, it was claimed, represents a mass of living matter, the denser accumulations of which, the formerly so-called "cells," are connected by more delicate processes or threads of the same, in the meshes of the network of which fluid or not-living matter is contained and in the vacuoles of which float corpuscles such as the blood-corpuscles, pigment granules, etc. Dr. Elsberg showed that for the purpose of designating the living formative matter in its simplest form, as necessitated by the views he had developed, the word "protoplasm" is etymologically incorrect, and has, also, already been used by some authors with a different meaning. He therefore prefers the word "bioplasm."

In conclusion, Dr. Elsberg spoke of the significance of the bioplasm doctrine and its connection with the questions of physiology and pathology. Practical benefits sometimes flow unexpectedly from investigations purely theoretical, and he showed how such biological researches might bring us a step nearer to the attainment of the highest aim of the physician—not only the cure, but the prevention of disease.

A NEW SPHYGMOGRAPH—ELASTIC MEMBRANE AND LIQUIDS FOR TRANSMITTING THE PULSATIONS OF THE ARTERY—BY DR. A. D. KEYT, OF CINCINNATI, O.

The following is an abstract of the paper presented:

The instrument is constructed upon the principle of utilizing elastic membrane and liquid, as water or alcohol, to receive and transmit to the writing lever the movements of the pulsating artery, instead of the steel spring and rigid bar employed for the purpose in the instruments already known to the profession. Elastic membrane and liquid are so closely allied in physical properties to the arterial coats and blood as to render them very natural media for the purpose indicated. The former, in its truthness and delicacy of response to distending forces and certainty of instantaneous return to its original state when the force is removed, is nicely adapted to receive the impressions of arterial movements; and the latter, in its lightness and incompressibility yet facility of movement in the direction of least resistance, is likewise nicely adapted to receive and transmit these movements. If now a piece of rubber cloth be placed flat and made adherent to the under edge of a metal or other rigid rim of proper shape and size, and then pressed down sufficiently upon a superficial artery, as the radial, it accurately closes over and fits the vessel as a sheath. The membrane thus embracing the artery is affected by the movements. It rises and expands with the diastole, falls and contracts with the systole, and receives the

exact impression of all the inner arterial changes. If now with this membrane *in situ* as a base, we fit to its rim a receptacle tapering upwards in the form of a flattened cone with a small circular opening in the top, and, filling the receptacle with water, fix over the opening a thin rubber membrane air-tight, the movements described as taking place in the lower membrane will be communicated to the liquid, and by it conveyed and transmitted to the small upper membrane, which will be distinctly seen rising and falling with the pulsations. If, next, a needle be placed with its flattened base fixed to the centre of a disk, and point impinging against the lower side of a delicate lever, the motions may be amplified to the requisite extent. It only remains, in order to get true and satisfactory motions in the tracing lever, that some device be resorted to for keeping the upper membrane always in equilibrium, standing, as it were, on the centre, ready to move up and down in strict obedience with the undulations in the liquid; for otherwise change of pressure upon the artery would throw the disk out of line of true and easy motion, and the result be *nil* or imperfect.

These principles were illustrated in the instrument exhibited.

To one of the lateral arms of the instrument is attached a glass tube, which can be placed in either the upright or horizontal position. When the instrument is in operation the tube occupies the upright position, and has three main uses: *First*, it affords a convenient receptacle for the displaced liquid which rises in the tube from the central cup as the instrument is pressed down upon the artery, and falls again into the cup when the instrument is raised off the artery. This provision allows the elastic membrane to closely embrace and press upon the artery and develop its proper tension—conditions requisite for the successful reflection of the pulsations.

The work exhibited consisted of miscellaneous tracings; tracings of the same subject in juxtaposition with those by Marey's instrument; tracings of different arteries, including the carotid and dorsal of the foot; tracings under regular gradations of pressure; tracings of young children; and tracings of heart disease, including one of the heart itself.

The Doctor in his remarks referred to his instrument as a new one, and believed that designation to be appropriate and just. He had taken some pains to inform himself as to the instruments employed in the study and illustration of the circulation, but had not found any which bear essential likeness to his own. It is true, he remarked, that the tambour polygraph and mercurial kymograph have points of suggestiveness, yet there is such a difference between these instruments and his own—difference in principle, in construction, in operation, and in results—that he did not hesitate to speak of the instrument which he presented as a new and distinct invention.

The last business before the Section was the reference of certain papers to Dr. N. S. Davis as a committee to report upon their value for the volume of Transactions, his action becoming the action of the Section.

The Section in each session was largely attended, and the rule was enforced relative to admitting papers which had already been read before medical societies, or published in whole or in abstract in medical journals.

SECTION ON SURGERY.

Dr. E. M. MOORE, of New York, Chairman.

Dr. S. W. BENHAM, of Pennsylvania, Secretary.

TUESDAY, MAY 4—FIRST DAY.

This Section was well attended, and some papers were brought before it that gave rise to considerable discussion. The first paper was upon "Some Results of Operative Surgery in the Lake States, Differing Somewhat from Results Obtained Elsewhere," by Dr. Andrews, of Chicago.

Dr. LEWIS A. SAYRE, of New York, read a paper entitled, "Partial Paralysis and Want of Co-ordination Dependent upon Genital Irritation."

The title of the third paper read was, "Operation for Extrophy of the Bladder," by Dr. Cyrus B. King, of Pennsylvania.

WEDNESDAY, MAY 5—SECOND DAY.

CESOPHAGEAL AUSCULTATION.

Dr. L. ELSBERG, of New York, presented a paper on this subject, which was referred to the Committee on Publication.

HYDRO-NEPHRITIS CAUSED BY THE FORMATION OF STONE IN THE PELVIS OF THE KIDNEY AND URETER.

Dr. LEON J. WILLEIN, of Terre Haute, Ind., read a paper upon this subject, which consisted mainly in the recital of facts concerning a single case, of which the following is a condensed statement:

History of Case.—A male patient, *æt.* 26 years, who could give no family history; was in the army two years in a cavalry regiment. Towards the latter part of his term of service he was thrown from his horse, and the horse fell on him with full weight. He recovered from his injury entirely, with the exception of a dull, deep pain in the lumbar region, and slight hæmaturia at times; the latter disappearing entirely for four years previous to his death. In 1866 he commenced peddling, without complaining of soreness in the side, or suffering any special inconvenience from a gradual enlargement of the abdomen which was then present. In July, 1874, he received a severe contusion of the back and left side, which caused much pain, and a few minutes after he discharged considerable blood with his urine; the discharge of blood was repeated occasionally for two weeks. About that time he felt a tumor in the left side, very painful upon pressure, and about the size of a goose-egg, and more or less movable. On the 20th of February, 1875, he received another injury, and when called to see him the following facts were elucidated: Abdomen greatly distended, especially upon left side, where a tumor could be distinctly seen, and was easily marked out by palpation and percussion. The shape of the tumor was similar to that of the kidney, and extended from the pubis to the sixth intercostal space, measuring 15 in. Transverse diameter at lower portion, 10½ in.; upper transverse diameter, 7½ in. Cystic degeneration of the kidney was suspected and coincided in by Dr. J. D. Mitchell, and puncture was proposed. The operation was performed with a trocar, and the cyst gradually emptied. The puncture was made about two inches to the right of the crest of the ilium. The amount of fluid removed was eight pints of a chocolate color, rather thin, inodorous, alkaline, depositing a bloody appearing sediment. After a few days the sack refilled. On the 10th of March a second puncture was made, near the same spot where the first one was made, and after about three quarts of thin fluid had been removed, there followed a thick, grumous, gelatinous substance, about a pint in quantity. On the 18th another puncture was made, and about one quart of blood and pus was discharged. Symptoms of circumscribed peritonitis were developed, and the patient died March 23d.

Autopsy, 24 hours after death. Great emaciation; skin yellow. On opening the abdominal cavity, a tumor was found, as already described, situated in the right side, extending from the ileo-pectineal eminence upwards to the sixth and seventh intercostal spaces. It proved to be an enormous kidney with a portion of the ureter, and it had acquired such a volume on account of the formation of a large stone in the pelvis of the kidney, and a small one, obstructing the flow of urine to the bladder, near its cystic connection with the ureter. The larger stone weighed over one ounce; the smaller about three drachms.

The tumor had formed adhesion over its entire surface. The ureter was greatly dilated, as well as the renal artery and veins. The glandular portion of the kidney was almost entirely destroyed. The right kidney was very much increased in size, but was quite healthy in appearance.

The points of interest in the case were:

I.—The reticence of the patient for so many years, without ever suffering from any irritation of the bladder or calculous nephritis.

II.—The perseverance at work, with healthy digestive organs, until four weeks before his death.

III.—The little evidence of inflammation until the two last weeks of his life.

THE THERMOSCOPE.

This instrument, devised by Dr. EDWARD SEGUIN, of New York, for the purpose of determining a very slight degree of heat, was brought before the Section by a delegate, in behalf of Dr. Sayre, who had the instrument in care.

Dr. J. MARION SIMS, of New York, exhibited and described the "Self-Acting Blowpipe," to be used in heating irons for the actual cautery.

THURSDAY, MAY 6—THIRD DAY.

REPORT UPON SYPHILIS.

The report upon Syphilis, read before the Association at Detroit, last year, by Dr. S. D. GROSS, of Philadelphia, was brought up for discussion in the Surgical Section at the present session. The discussion was quite animated, and participated in by Drs. Andrews, of Chicago; Kennard and Hodgen, of St. Louis; Garcelon, of Maine; Bronson, of Massachusetts; Morris, of New York; and Gross, of Philadelphia.

It turned upon the question of national legislation with reference to this disease, and upon motion the Committee of the Section was instructed to elaborate and report, for consideration at the session of the Association for next year, a draft of a national law. The recommendation of the Section relative to this question was sustained by the Association in general session.

CIRCULAR AMPUTATION—CUP-SHAPED STUMP—STUMP TREATED AS AN OPEN WOUND.

A paper upon this subject was presented and read by Prof. LINK, of Indiana. The advantages claimed for this mode of operation and subsequent treatment of the stump consisted in freedom from suppuration, absence of pain, and a comparatively short period for the healing process to be completed.

SECTION ON OBSTETRICS.

Dr. W. W. BYFORD, of Chicago, Chairman.

Dr. S. C. BUSEY, of Washington, Secretary.

The following papers were read before this Section: On Pessaries. By Dr. John Morris, of Baltimore. Retroversion of the Uterus during Pregnancy. By Dr. A. S. Leaton.

Phlebitis following the Hypodermic Injection of Ergot in the Treatment of a Fibrous Tumor of the Uterus. By Dr. Allen, of Massachusetts.

Three Cases of Myo-Fibromata treated with Ergot. By Dr. J. H. Thompson, of Washington, D. C.

Normal Standard of Women for Propagation. By Dr. Allen, of Massachusetts.

On a Peculiar Disease of Infancy called Pigmentation. By Dr. Wright, of Ohio.

Congenital Occlusion and Dilatation of Lymph Channels. By Dr. S. C. Busey, of Washington, D. C.

Report of the Chairman of the Section on Fibroid Tumors, read before the Association in general session. The report was discussed at some length by Drs. Sims, Atlee, Byford, and others.

Of the above papers the last two were referred to the Committee on Publication. The remainder were referred back to their authors. Several papers were presented which were not permitted to be read. The Section was upon the alert with reference to papers which came before it as second-hand matter.

SECTION ON STATE MEDICINE AND PUBLIC HYGIENE.

Dr. H. I. BOWDITCH, of Boston, Mass., Chairman.

Dr. H. B. BAKER, of Lansing, Mich., Secretary.

The following papers were read before this Section: Floating Hospitals. By Dr. Wm. F. Thoms, New York.

Menlock Poisoning. By Dr. A. N. Bell, Brooklyn. Report upon the Climatology and Diseases of Nebraska. By Dr. James H. Peabody, of Omaha.

Diseases of Minnesota and the Northwest. By Dr. D. W. Hand, of St. Paul.

Dr. Bowditch exhibited and explained diagrams illustrating the apparent influence of cloudy days upon the proportion of deaths from consumption, during a series of years from 1810 to 1867, inclusive.

Report of certain Papers and Correspondence of the Chairman, relative to the Work of the Section, and the Establishment of a National Board of Health. By Dr. H. B. Baker, Michigan.

A Partial Report upon Ventilation.

Climatology and Sanitary Report of Florida. By Dr. John P. Wall, Tampa, Fla.

Correspondence.

ERIE COUNTY MEDICAL SOCIETY AND PRELIMINARY EDUCATION.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Your editorial of April 17th on Preliminary Education seems well timed and suggestive.

You will be glad to hear that the inertia of our profession in regard to this important matter is not quite as profound as you suppose—that the earnest efforts of the reformers in our National Association and State Society have not been fruitless.

For four years there has been a systematic and sustained effort in our Erie County Medical Society to faithfully execute our by-laws in this matter, and we can now claim "the preliminary examination of students of medicine" in our Society to be a fact.

The obstacles we have had to overcome were those you would surmise—lethargy of the many, and covert opposition of the few. The move which finally aroused the Society from its indifference and convinced the few of the inexpediency of further opposition, was taken at our annual meeting in January last, when

the Primary Board preferred charges of knowing, repeated, and wilful violation of our by-laws against a prominent member of our faculty and Society, in the admission of students to his office at various times during the last three years without the primary examination.

The discussion which grew out of this brought the subject in all its bearings thoroughly before the Society, and although the resolution introduced by another member of the faculty, and adopted by the Society, was one of diplomatic indefiniteness as a resolution of censure, and a good example of the difference between principle and policy, yet it plainly committed the Society to the enforcement of this preliminary examination.

In conclusion, allow me to suggest a thought in this connection.

The laws regulating the practice of medicine, and the charters of our various medical schools, all recognize that the study of medicine has a definite commencement, a prescribed course, and a fixed termination; that to become a legally practising physician, one must begin the study of medicine by receiving the preliminary certificate of the censors, continue it for three years with a legally practising physician, graduate from an incorporated medical school, and unite with an incorporated county medical society.

You will observe that three out of four of these legal steps are under the control of our county societies.

For the last three years the only students who have legally begun the study of medicine in this State are those who have been certified by the State or County Censor, and as the power to grant the degree of Doctor of Medicine which is bestowed upon our medical schools is not absolute, but always conditional, and as one of these conditions is, "that applicants shall have studied medicine for three years with a legally practising physician," it follows that degrees granted to students who have studied in an illegal way, who began the study of medicine in this State during the last three years, without the preliminary examination, have been granted contrary to law, and do not entitle the holders to "all the rights and privileges of the practice of physic and surgery." Is not this an important matter?

And is not the day near at hand when applicants for admission to county societies will be obliged to show that they have legally begun, conducted, and ended the study of medicine.

In general terms, the college will supply as poor material as the county societies will admit.

Let the societies unite in the declaration that they will accept of nothing that falls short of the legal requirements, and the colleges will find it expedient to comply with the demand. H. R. HOPKINS, M.D.

BUFFALO, N. Y.

THE VALUE OF SPECTRAL ANALYSIS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Sickness has prevented me from noticing Dr. Piffard's parting assertions in THE RECORD, April 3, 1875, "that I have systematically and persistently misquoted him, myself, and the authorities to whom I had referred in support of my views."

The readers of THE RECORD will have no difficulty to satisfy themselves that these assertions are utterly reckless and absolutely without foundation.

In my original lecture, see RECORD, October 15, 1875, which Dr. P. undertook to criticise, I stated "that sun-lines invisible under ordinary circumstances can be made evident at both the red and violet parts of

the spectrum." Dr. P. copied the word "evident" in his first criticism, November 16, 1874. He must therefore have been aware of the precise word used. In my reply January 30, 1875, in quoting the above sentence, by a typographical error, the word "evidently" was printed.

The favorable notice in Virchow's *Jahresbericht*, wherein the correctness and completeness of my views on spectral analysis in pathology and physiology are honorably recognized, is a tribute to an American student which loses none of its importance on account of Dr. P.'s attempt to treat it disrespectfully.

S. WATERMANN.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from May 9th to May 15th, 1875.

KEENEY, C. C., Surgeon.—During absence of the Medical Director of the Department to perform his duties. S. O. 40, Department of California, April 29, 1875.

FRANTZ, J. H., Surgeon.—Relieved from duty at Columbia, S. C., and to comply with S. O. 73, c. s., A. G. O. S. O. 59, c. s., Department of the South.

GIBSON, J. R., Assistant Surgeon.—When relieved by Assistant Surgeon DeWitt, to comply with S. O. 73, c. s., A. G. O. S. O. 59, c. s., Department of the South.

BAILY, J. C., Surgeon.—Assigned to duty at Post of Columbia, S. C. S. O. 59, Department of the South, May 6, 1875.

HEIZMANN, C. L., Assistant Surgeon.—Leave of absence extended 3 months. S. O. 89, A. G. O., May 12, 1875.

DEWITT, C., Assistant Surgeon.—Assigned to duty at Charleston, S. C. S. O. 59, c. s., Department of the South.

PAULDING, H. O., Assistant Surgeon.—Assigned to duty at Fort Abraham Lincoln, D. T. S. O. 78, Department of Dakota, May 6, 1875.

FINLEY, J. A., Assistant Surgeon.—Assigned to duty at Cantonment on the North Fork of the Red River, Texas. S. O. 67, Department of the Missouri, May 5, 1875.

DELOFFRE, A. A., Assistant Surgeon.—When relieved by Assistant Surgeon Finley, assigned to duty at Fort Larned, Kansas. S. O. 67, c. s., Department of the Missouri.

MAUS, L. M., Assistant Surgeon.—Assigned to duty at Frankfort, Kentucky. S. O. 59, c. s., Department of the South.

LEEUEWENHOEK.—A committee has been formed at Delft, in Holland, to make arrangements for the celebration, on September 8th, of the second centenary anniversary of the discovery of microscopic animals by Leeuwenhoek, a native of the town. It is intended to render the occasion especially interesting by the exhibition of the microscopes which the distinguished naturalist made, and of letters and memorials of him. The committee are also endeavoring to raise a fund for the purpose of founding a gold medal, to be awarded under the name of the Leeuwenhoek medal, every tenth year, to the Dutchman or foreigner who shall have done most for the advancement of microscopical science. The award is to be made by the Royal Academy of Sciences at Amsterdam.

Medical Items and News.

U. S. MARINE HOSPITAL SERVICE.—Dr. J. M. Woodworth, Supervising Surgeon-General, U. S. Marine Hospital Service, has gone to San Francisco, Cal., to formally open the new pavilion hospital at that port.

The following changes in the assignment to duty of officers in this service, have been made:

Surgeon F. W. Reilly, transferred from Philadelphia and Baltimore to Cincinnati, Ohio.

Surgeon Orsamus Smith, transferred from New Orleans to Louisville, Ky.

Surgeon P. H. Bailhache, transferred from Louisville, Ky., to the Supervising Surgeon-General's office at Washington.

Surgeon John Vasant (passed the Board of Examining Surgeons April 30, 1875, and appointed into the Medical Corps of the Service May 8), assigned to duty at New Orleans.

Assistant-Surgeon Samuel Houston, assigned to duty at Baltimore, and Georgetown, D. C.

Assistant-Surgeon Henry E. Muhlenberg, Jr., transferred from New York for temporary duty at Boston.

Assistant-Surgeon W. H. Hutton (passed the Board of Examining Surgeons April 30, 1875, and appointed into the Medical Corps of the Service May 8), assigned to duty at New York.

DR. MARY PUTNAM-JACOBI has lately received from the Medical Faculty of Paris, a bronze medal (second class) for her inaugural thesis on "Neutral Fat and Fatty Acids." The members of the committee making the award for the session of 1870-71 (which was the time when the thesis was written) were MM. Wurtz, Tardieu, Depaul, Sappey, Dolbeau, Vulpian, Vernueil, Axenfeld, Gubler, and Darenberg.

Of three hundred others, thirty-eight were entitled to a special examination for medals. Of these seven received the silver medal, fourteen the bronze, while the remainder were honorably mentioned.

THE FIFTH ANNUAL REPORT OF SAINT MARY'S FREE HOSPITAL FOR CHILDREN, at 407 West Thirty-fourth street, shows that ninety-four patients were treated for one hundred and four diseases, at an average cost per patient of about \$67, exclusive of donations, and a mortality of twelve and one-half per cent. The supporters of the institution are making an effort to purchase the property at present occupied by them.

DR. BOUCHUT, of Paris, has brought down upon himself the maledictions of the Parisian clergy, who declare that his recently published articles on hypnotism contain heretical sentiments. Their further publication in the *Journal Officiel* has been, in consequence, suspended.

THE BARON DE WALDECK, of Paris, well known for his studies of Central American antiquities, celebrated his one hundred and ninth birthday in March last.

WEEKLY BULLETIN OF MEETINGS OF SOCIETIES.

Monday, May 24.—Medical Society of the County of New York.

Tuesday, May 25.—American Microscopical Society; Yorkville Medical Association.

Wednesday, May 26.—New York Pathological Society.

Thursday, May 27.—New York Medico-Legal Society; Brooklyn Pathological Section; Jersey City Pathological Society.

Friday, May 28.—Medical Library and Journal Association. Report on Dermatology: Dr. Geo. H. Fox.

Original Communications.

CONIUM: AND ITS USE IN DISEASES OF THE EYE.

By EDWARD CURTIS, A.M., M.D.,

PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

[Read before the New York County Medical Society, April 26, 1875.]

PART II.

Now as to the cause of sea-sickness in hemlock-poisoning. As regards the part played by the eyes, there is not now, of course, any disturbance of the customary physical relation between the actual status of eyeballs and visual image, such as occurs when looking at the heaving sea. Hence, under hemlock, there should, unlike what obtains on the ocean, be no confusion whatever when the eyes are fixed. And such, it will be remembered, is exactly the clinical fact. But suppose the poisoned individual rashly looks about, thus calling into action the half paralyzed ocular muscles. There is still, it is true, no change in the usual correlation between the shifting of the retinal image and the actual movement of the eyes, but, what comes to the same thing in its effect on the brain, is that there is a disturbance now as between the status of the image and the *intended* or *anticipated* ocular movement; and this for the simple reason that now the *intended* and the *actual* motion imparted to the eyeballs, on attempting to turn them, no longer correspond. For when such attempt is made during the poisoning of hemlock, though the necessary motor order is issued in due form by the co-ordinating centre, yet from the poisoned state of the nerve-endings in the muscles, such order does not reach the muscular tissue in its full intensity. Hence the muscles, executing blindly only such instructions as they actually get, carry the eyes in the proper direction it is true, but not to the intended extent. In other words, the eye when turned, or rather *ordered* to be turned so as to bear on a given object, does not do so, but stops opposite a point a little short of it, as is fully realized by the experimenter. But that means, that now a conscious order for a definite movement of the eyeballs, does *not* produce the hitherto accustomed change of position of the retinal image. In other words the habitual sensori-motor association, once more, between the consciousness of a motor command and the perception of the visual result, is now as much changed, though by a different agency, as in looking abroad from the deck of a rolling ship. In both cases the physiological trouble is that visual impressions are now inconsistent, according to the teaching of past experience, with the conscious or intended state of motion or rest of the eyeballs. But in the one case it is because the heaving sea shifts the retinal image *directly* in an unexpected way, while in the other case this happens *indirectly* through failure of the ocular muscles to execute in full a projected movement. In the one case the difficulty is an unnatural mobility of the objects viewed, in the other an undue immobility on the part of the eyes themselves. Hence at sea, where the cause of the disturbance is extraneous and always present, looking at the moving water should develop sickness whether the eyes are fixed or moved over the field, and so it does. But in hemlock-poisoning, where the cause is internal and has solely to do with the motor function, all confusion

should be absent when the eyes are held steady, and appear only when they are moved: and such again is the observed fact.

When the hemlock paresis becomes general, giddiness follows any attempt to walk or make almost any decided muscular effort, even if the eyes be shut; and the explanation is again the same. The conscious orders from the volitional centre and the receipts of results through the muscular sense no longer bear the customary relation, because the muscles do not execute the command exactly as originally issued. An order to the leg to step forward twenty-four inches may be followed by a stride of only eighteen; and one to the muscles of the trunk to bear up against a ten-pound side-lurch of the whole frame, results in a resistance to only eight pounds pressure, whence of course the body totters. This curious failure of the muscles to execute in full a given order is no fancy picture, but one that can be experimentally verified. Thus while under the influence of hemlock, as already described, I went to attach a gummed label to the little vial from which I had partaken. Picking up the label, I without any thought made the usual motion to carry it to my tongue for the purpose of moistening it, but instead of accomplishing that intention the *hand* actually made the movement required in mid-air, some three inches short of its mark, and I was then obliged to do what seemed subjectively equivalent to willing the hand to go as far as half way down the throat, in order to, actually, bring the fingers to the tongue. Proceeding then to the manœuvre of sticking the label upon the bottle, precisely the same circumstance happened over again.

Comparing now this matter of keeping the balance when under hemlock and when on ship, the difference in the cause of the trouble in the two cases is just this: The landlubber, walking on a rolling deck, goes to plant his foot on a given spot, and lo! the spot is not there,—it has swayed out of place; while, when the hemlock-experimenter attempts the same, lo now it is the *foot* that is not there, for it has been erroneously set down somewhere else than on the spot intended. The physiological resultant is obviously the same, and the same cerebral confusion provoking sea-sickness occurs in both cases for a common reason.

Turning now to the therapeutics of hemlock, the obvious use of the drug is to neutralize spasm or enforce muscular rest by establishing a certain degree of temporary paresis, and thus, secondarily, to remove morbid symptoms due to spasm or great motor restlessness. The field of action for such therapeutics is plainly a wide one, and, as is well known, conium has been a good deal used of late for such purposes. But it is not my intention to discuss all the applications of the remedy, and I will only say, on the general subject of hemlock-therapeutics, that to do any good the drug must be given so as to produce some degree of its peculiar physiological effects. One would expect, considering the short duration of the influence, that the relief obtained through the medicine would be correspondingly brief. But though this is very often the case, the rule is not invariable. For it is a well-known therapeutic fact that a morbid symptom, when forcibly crushed, as it were, by some neurotic, does not always immediately recur, after the drug has let up its grip. And just this thing may happen, as I have myself observed, in the medicinal use of hemlock. A spasm quenched by conium-paresis has remained relieved many hours after all other conscious influence of the drug had vanished.

But my sole object in this part of the paper is to call attention to a particular use of hemlock which I

do not think is accorded the importance it would seem to deserve. I refer to its employment as a means of combating the distressing "blepharospasm" that accompanies many acute inflammations of the cornea, conjunctiva, and sometimes the iris. Of course there is no need to discuss the affection itself; it is common enough, and all know that though itself a mere consequence of the inflammation, it yet reacts on the main disease, aggravating its intensity and prolonging its duration. Here, then, is one of the instances where a therapeutic attack on what is purely a secondary disturbance, will indirectly, if successful, avail towards the cure of the primary disease. Now this blepharospasm is not, as its name would seem to import, simply a spasm of the orbicularis muscle. The third cranial nerve is evidently involved in the erethism, as is shown by the contracted pupil, the unnatural resistance of the iris to the action of atropine, even when not itself inflamed, and the uncontrollable rolling of the eyeball upwards on the least attempt to separate the lids. It is probable, I think, that all the ocular muscles may be involved, but there is no way of proving this.

This blepharospasm is well known to be often exceedingly obstinate in yielding to treatment, and there is, therefore, here a genuine field for trial of new remedies. And *hemlock* naturally suggests itself in this connection; first, from the fact that it is a powerful and at the same time simple motor paralyzer in general, and secondly, because the ocular muscles, which are to a considerable extent concerned in the disorder under consideration, happen at the same time to be specially subject to the physiological influence of this drug. It is, therefore, not surprising that so shrewd an observer as Harley should early point out this application of conium; and in his book on the "Old Vegetable Neurotics" he records a very considerable success with it in the blepharospasm depending on ophthalmic inflammations. I accordingly determined to try it myself, but not wishing to bias my judgment by inconclusive experiments, I waited till I should meet a case, severe and protracted in itself, occurring in an adult who could intelligently record his own sensations, and who could be taken into hospital, so as to be treated with full doses under the control and observation of the resident surgeon. Such a case presented itself last January, in my service at the Eye Infirmary.

A young man, of twenty-three years, an old sufferer from chronic conjunctivitis, was struck on the left eye by a bit of ice last September. Violent inflammation followed, lasting some weeks. He completely recovered, as he states, but after prolonged exposure to cold, one day in January, a sudden relapse occurred, and a week later the patient presented himself at the clinic for the first time. His was then a typical case of the highest grade of blepharospasm. Both eyes were spasmodically held shut, and not only could the patient not separate the lids in the least by any voluntary effort, but it was next to impossible for the surgeon to do the same by anything short of extreme violence. As usual in such cases there were also excessive intolerance of light and constant severe pain, the latter almost wholly depriving the sufferer of sleep. An examination of the affected eye, made with extreme difficulty, showed a sharp iritis, with the free edge of the iris already glued fast to the lens at almost all points, and a large focus of diffuse inflammation of the cornea near its centre. The man was at once admitted as a house-patient with a view to trying the hemlock. But as I did not feel justified in withholding atropine from a case of iritis, I waited

awhile before beginning with conium, in order to eliminate the effects due to atropine and the other usual measures, from the intended observation. Accordingly, the patient was at first treated in the customary way by local instillations of a strong atropia solution, warm applications, rest in bed in a dark chamber, and such general measures as were appropriate, including hypodermics of morphine to relieve, if possible, the pain and spasm and procure sleep. But five days of this treatment resulted in no benefit whatever. The persistent spasm and pain remained as bad as ever, morphine giving no relief; the inflammatory process showed no sign of abating, nor did the adhesions between the iris and lens yield in the least to atropine. There was here then a good foundation for a reliable observation on what hemlock might do. Accordingly, at the end of the five days, I requested our resident surgeon, Dr. W. O. Moore, while continuing the previous treatment, to give the patient daily one or two full doses of Squibb's fluid extract of conium fruit, which I had previously tested on my own person to be an active preparation. The initial dose was to be forty minims by measure, and subsequent doses were to be regulated by the effects, the drug to be pushed if necessary to its full physiological limits. The object of giving isolated large doses, instead of keeping up a steady influence by frequent small ones, was so that the same day might offer for comparison the state of things when the system was under hemlock and when wholly free from its influence. Dr. Moore entered into the undertaking with interest, and I wish to express my acknowledgments to him for his skill in carrying out the general idea, and for the full and careful notes of the results of the treatment, from which the following abstract is compiled:—

The first dose was forty minims at 11.30 A.M., January 27. In half an hour the spasm broke, with decided abatement of the pain, and the patient for the first time in twelve days could open his eyes of his own will. At the same time the physiological effects of the drug were seen in giddiness and staggering on trying to walk. The man shortly dropped into a doze, as was natural after relief from the severe pain that had been destroying his rest for so long, but awoke at 4 P.M., *i.e.*, four hours and a half since taking the hemlock, with all conscious physiological effects of the drug gone, and the spasm and accompanying pain back again as bad as ever. As usual he slept poorly during the night on account of the constant pain.

The next day thirty minims only were given at 10.15 A.M. In half an hour again there followed the same prompt relief of the spasm, and with it the pain, as on the day before, but with less pronounced general paresis, as would be expected from the smaller dose. All effect having passed off in a couple of hours, Dr. Moore gave a second dose of thirty minims at 12.30. Swiftly again the same relief was experienced, but now with more general physiological effects than with the dose just previous. This being the day of my attendance at the Infirmary, I saw the patient at 3.30 P.M., just three hours after his last taking of the hemlock. By that time the general paresis, with the accompanying giddiness, etc., had all passed away, but now was observed the interesting point already spoken of, that the *therapeutic* effect persisted. Indeed, I never saw a more complete reversal of a clinical picture than that presented by the patient now, as compared with his condition when I had last seen him, just before the hemlock treatment was begun. Instead of shrinking and cowering from the light with eyes spasmodically shut, and the orbicularis quivering and tense like the biceps of a gymnast, on trying to force the lids apart,

—instead of this aspect, the patient to my amazement got out of bed and boldly walked to the full open window, with head erect and eyes naturally and easily open. Moreover, now I noticed that the inflammatory process itself had begun to abate, and that the iris, for the first time, was yielding to the atropine. More or less good effect seemed to last through the night—or at any rate the patient slept better than any night previous.

The next day—the third of the hemlock treatment—only a single thirty-minim dose was given, but it now produced no effect.

The following day forty minims were given, and in forty minutes the usual physiological effects were developed, with relief of the nervous symptoms as before, though not so marked as on the day when two thirty-minim doses were taken. Still a good night's rest followed.

The next, the fifth day, the same dose was administered with the same result, but on the following, the sixth, Dr. Moore withheld the hemlock altogether, as a controlling experiment. Prompt relapse of all the symptoms followed; more pain and spasm than at any time since the conium treatment had been begun; pupils again contracting despite atropine; vascular injection of the globe more marked. Patient also had a bad night from severe pain. The hemlock was thereupon resumed in single forty-minim doses daily, and produced the customary relief of the spasm and pain, but, what is interesting, without now causing giddiness or staggering. Possibly by this time the patient had from practice acquired his *hemlock-legs*, if an analogous condition to "sea-legs" can be established under the habitual use of the drug. After three days the dose was increased to fifty and then to sixty minims, and a few days later, the nervous symptoms being well under control, the systematic use of the medicine was discontinued. But as the inflammatory process in the iris and cornea still hung on with great obstinacy, and as there was a possible suspicion of an old syphilitic taint in the man, iodide of potassium in full dose was given at a venture, and with the happiest result. The disease began at once to recede, and by the thirteenth of March the eye was perfectly well, a single point of attachment of the iris to the lens only remaining. On that day a little surgical operation for separating this adhesion was performed, but was unfortunately followed by a sharp return of the inflammation with a renewal of all the previous symptoms. Again the patient was at first treated without hemlock, and now with iodide of potassium along with the local measures. But nothing availed, and so after eight days the conium dosing was renewed, beginning with forty minims, increased after a few days to a fluid drachm once or twice daily. Precisely the same results followed as before: the spasm and pain would be relieved for hours at a time, and on the second day of the hemlock treatment, the iris, which had again resisted atropine, began to yield once more. Six days later the pupil was fully dilated and the iritis rapidly subsiding. Conium was given *pro re natâ* for two weeks more, the patient often calling for it of his own accord, when all need for it having disappeared it was discontinued. During this period the fluid extracts of two other makers were tried, but neither of them, even in one hundred minim doses, produced the slightest effect, physiological or therapeutic.

At the February meeting of the New York Ophthalmological Society I reported this case so far as it had then progressed, and called the attention of the members to this use of conium in the blepharospasm of ocular inflammations. Several proposed to try it, but

I know of the results of only three cases, as follows: Dr. O. D. Pomeroy, at the next meeting of the Society, reported the case of a girl, nine years old, with granular lids and ulcerated cornea, accompanied by intense blepharospasm and photophobia. He gave ten drops of Squibb's extract, while the patient remained in the clinic room. In twenty-five minutes the child could partially open the eyes, and after the lapse of forty, opened them fully and naturally, and faced the light without flinching. And what is exceedingly interesting, there is reported to have been no return of the spasm from that moment, though but the single small dose was given. Next, Dr. Loring tried conium in a case of severe and persistent blepharospasm, accompanying granular lids and pannus, which for two weeks had resisted all other treatment. I am indebted to Dr. Moore again for the notes of this case. Two twenty-minim doses were given the first day, and an hour after taking the second the eyes were voluntarily opened for the first time since admission to the infirmary, and the pain greatly abated. The next day almost entire relief of the nervous symptoms followed a single forty-minim dose, and for five days more similar daily doses were given, during which the acute symptoms of the disease steadily receded. The drug was then no longer urgently called for, and as it produced in this case distressing giddiness was gladly discontinued. Lastly, as is now so well known, the hemlock was tried in Brooklyn, in a case of general facial spasm, involving the orbicularis, but as would seem from the patient's own memorandum, even his self-administered fatal dose had no influence to quell the disorder. But as, if I understand the case aright, this was not the usual blepharospasm of inflammatory ophthalmic disease, it is not properly comparable to the foregoing.

The only other case in which I myself have given hemlock a fair trial, was that of a young girl, eighteen years old, again a sufferer from intense blepharospasm consequent on an acute outburst of granular lids and pannus. Here, as in my first case, I took the patient into the infirmary and for a week tried the usual remedies, but without the slightest benefit. Hemlock was then administered, first in twenty, then thirty, and finally forty-minim doses of Squibb's fluid extract of the fruit, once or twice daily. But here the drug gave only very moderate relief from the spasm and pain, and there was no abatement of the inflammatory process itself. Moreover, the patient was so distressed with sea-sickness following its use—once actually vomiting—that she begged it might be withheld. Accordingly, after eight days' trial, I abandoned the medicine and performed the so-called canthoplastic operation; that is, splitting the outer canthus and stitching the conjunctiva to the edges of the skin wound. Prompt benefit followed; the patient immediately began to improve in all respects, and indeed made one of those marvellously quick recoveries that sometimes happen after this simple little procedure.

To sum up, of course I am aware that nothing definite is proved by so few cases as I am able to present to-night, especially where, as in this instance, the results are discrepant. Nor should I have thought of bringing this matter up at all at the present time, had it not been for the fear that the recent singular accident in the use of hemlock might unduly prejudice the profession against it. But I think that taking these cases with the results of Harley's original experience, it is shown that while conium may practically fail entirely, as in my last case, still its success in others warrants an extended and impartial trial of the drug in the very common and distressing condition under consideration.

HALLUX VALGUS, EXSECTION OF METATARSAL BONE; MORTIFICATION AND DEATH.

WITH SOME REMARKS ON ESMARCH'S BANDAGE.

BY J. H. POOLEY, M.D.,

YONKERS, N. Y.

Mr. F.—a farmer by occupation, a hale, hearty-looking man, who says he is 75 years of age, but certainly looks ten years younger than this, and who has always been healthy, consulted me at my office on March 9th, 1875. He has the deformity known as Hallux Valgus, or abduction of the great toe on both feet, which has existed for thirty years or more, and which he attributes, correctly no doubt, to the practice of wearing tight boots when he was a younger man. On the left foot the great toe overrides the lesser toes, on the right it overrides them; on each, the great toe is bent or abducted to as nearly a right angle as possible, and the consequent projection of the head of the metatarsal bone is occupied by a large swelling or bunion.

Three years ago the wheel of a loaded ox-cart passed over the deformed joint of the left foot, hurting it very severely, and disabling him for a short time. From that time to this he has had more or less trouble from it, but nothing severe until within the last three months, since which he has been almost constantly confined to the house, and in spite of a variety of treatment it has lately been getting rapidly worse.

Upon inspection I found the site of the deformed metatarso-phalangeal articulation occupied by a large, much inflamed bunion—it was red, hot, tender, and painful, and in its centre was a small circular opening, from which a slight amount of thin discharge issued, and from which projected some shreds of sloughy tough tissue, probably ligamentous. On introducing a probe I thought I could detect bare bone, but was not quite sure of this; he bore motion of the joint pretty well, but winced considerably when the joint-surfaces were pressed together. I advised exsection of the head of the metatarsal bone, as the means most likely to afford him complete and permanent relief.

He instantly acceded to the proposition, being glad of any prospect of relief from his sufferings, which had been protracted and severe, and the 11th of March was fixed upon for me to go to his house, about four miles from my own, and perform the operation.

Accordingly on the afternoon of March 11th I operated, assisted by Dr. Nordquist of Tuckahoe, the family physician, and Dr. F. S. Grant of Yonkers.

Ether was administered, and Esmarch's bandage applied in the usual way, which answered its purpose perfectly, as not a drop of blood was seen during the whole operation. The diseased articulation was much more inflamed than when I had seen it two days before, probably as the result of the unwonted exercise of it in coming over to see me; it was exquisitely tender and painful, so much so as to have completely deprived him of sleep the night before, despite hot poultices, and repeated doses of McMunn's elixir of opium. An incision was made over the most prominent part of the swelling down to the bone, when the head of the metatarsal bone was found to be in a carious condition.

The soft parts were separated from the bone, the ligament except on the side toward the next phalanx divided, and the joint opened; a chain saw was then passed around the neck of the bone, and it was sawn through, the bone was then twisted inwards and the remaining ligament divided, which completed the

operation. I have been thus particular in describing the operation, because although other methods have been practised, it seems to me this is the best. It is a very simple affair, and yet may be made rather embarrassing and tedious by want of attention to details, which are therefore not unimportant. The chain saw is preferable to any other instrument for the division of the bone, any other form of saw almost necessarily lacerates the soft parts to some extent, and bone cutters are very apt to splinter the bone. It seems to me also that there is an obvious advantage in dividing the bone before attempting the almost inaccessible ligament on the side toward the adjacent phalanx, as the command thus given of the bone, and the twisting and turning of it materially facilitates this last step of the operation.

After the completion of the operation a compress and bandage were applied, and warm water dressing ordered, with an opiate at night if necessary.

March 12th. Patient passed a comfortable night, only taking his anodyne once, and sleeping more than for many nights previously; wound looks well, to continue warm water.

March 14th, Sunday. On Friday night, the date of my last visit, some sloughing of the wound began to be noticed, which continued increasing all day Saturday, and when I saw him the whole wound was in a condition of mortification which extended up on to the instep, or about the upper end of the metatarsal bone, and also threatened the great toe. Warm solution of carbolic acid, which had been substituted by Dr. Nordquist for the simple water, was continued, quinine and iron also prescribed. His pulse was only 80 and full, tongue slightly coated; there was a large painful swelling of the right elbow, no rigors, afternoon fever, some delirium, no pain except in the elbow, which was red, hot, and slightly tense.

March 16th. Mortification has spread, involving the great toe, which was completely dead, and was removed by simply cutting through some sloughing tendons with the scissors.

The other toes look dubious, but there is a distinct line of demarkation showing itself on the instep. Quinine and iron which he had been taking every four hours, to be given every three, and one minim of carbolic acid to be added to each dose.

General condition of the patient very much the same as at last date, has had no chill, pulse 88, elbow still swollen and painful, though not perceptibly more so than at last report.

March 17th. Mortification has involved all the toes, and spread over the sole of the foot and outer portion of the dorsum. Patient weaker, more delirious, pulse 100, tongue heavily coated, not dry, no chill, elbow more swollen, is not willing to take as much nourishment as desirable. Give tonic and carbolic acid every two hours, and push the stimulants.

March 18th. Going on from bad to worse, gangrene spreading from the sole of the foot up the calf, nearly as high as the knee. Patient weak, pulse 90, temperature 101½, no chill, but sweats a good deal, and is stupid and dozing the greater part of the time; when awake, constantly delirious.

Opinion expressed that all operative interference is out of the question, and that he will scarcely survive more than twenty-four hours. He died the following day, March 19th, at 10½ A.M. I must mention that in the intervals between my visits he has been most assiduously attended by Dr. Nordquist.

After much and serious reflection, I cannot avoid the conclusion that the disastrous result of this case is due, in part at least, to the application of the

Esmarch's bandage. A fear that sloughing might arise in many instances from the complete exsanguination of the tissues by this new appliance, has been felt and expressed in several quarters, and would seem theoretically to be well founded, but I do not know that it has been verified by the publication of any such instance as the present.

I do not leave out of sight this patient's advanced age, but making all due allowances for that, and in view of his fine physique, and perfect health, it would not have deterred any one from the performance of a much severer operation. I cannot entirely acquit the elastic bandage; and I have been led in view of this distressing case to look at my former experience with the new method in a rather different light from that in which I had formerly regarded it. I stated in some remarks which I made at a meeting of the New York County Medical Society, November 27th, 1874, that I had used Esmarch's method in six major amputations, without any bad results *attributable to the method*: in this statement I was perfectly sincere, and so thought most fully at the time, and ever since until the occurrence of the present case, but am not so sure of it now.

In one of the cases then referred to there was some sloughing of the flaps, which was attributed at the time to the double fact that the amputation was done for a railroad accident, which often inflicts injury upon the tissues beyond what is immediately apparent, and also that the patient was a most wretched broken-down sot. Since then I have performed a Syme's amputation at the ankle with Esmarch's bandage, in which case the flaps sloughed; this was attributed to the existence of unhealthy tissue in the neighborhood, and we all know that the flap in this operation has rather a precarious existence at the best; the same patient recovered perfectly and rapidly, from a reamputation of the leg, also with Esmarch.

These experiences, in the light of the present case, have somewhat shaken my faith in the perfect safety of the method, and lead me to sound a note, not of alarm, but of caution, on this subject. Of course the method is not to be discarded on account of two or three, or even a score of unfortunate cases; but the question is, must we not discount a little from the idea of its almost universal applicability?

It would seem that there may be danger in its use in old persons, and more so in operations on the toes and feet than in the limb higher up, and nearer the centre of circulation, or in the upper extremity, and in vitiated and broken-down constitutions. And the danger in operations on the feet may be increased by the fact that as a rule they take up more time in their performance, and so deprive the parts bandaged of their nutritious fluid too long for safety. I am in no position to assert anything, even were I so disposed, but I throw out these doubts and questions for the consideration of others.

Time, which tries all things, will certainly bring us at last to the true estimation of this, as of every other novelty, and in the meanwhile I take the liberty of asking that if any one knows of similar experiences, they will favor the profession with them, that all may compare notes and see where we stand. The favorable side has been abundantly presented; if there is an unfavorable side, let us have that too. In closing I would record my firm persuasion that even should we be obliged to admit that there are many cases where this new method is dangerous, there still remain enough where it is undoubtedly applicable and valuable, to make it one of the most brilliant acquisitions of modern surgery.

Original Lectures.

ON PULMONARY PHTHISIS.

By FRANCIS DELAFIELD, M.D.,

ADJUNCT LECTURER PRACT. MEDICINE AND PATHOLOGY, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

LECTURE II.

AFTER considering the subject of scrofulous inflammation, our next step is to inquire into the nature of tubercles.

What are tubercles? Instead of answering this question directly, I will state to you the different lesions which have been called tubercles. The first systematic classification and nomenclature of tubercles was elaborated by Laennec in the early years of the present century, and the names which he adopted are still in use. He held that there is only one tuberculous matter, and that this is an accidental, not an inflammatory product. He admitted of only one kind of pulmonary phthisis, the tubercular. He classed the tubercles of the lungs into two species, the isolated and the infiltrated tubercles. Of the isolated tubercles, he distinguished four varieties—miliary, crude, granular, and encysted tubercles. Of these, the granular, miliary, and crude tubercles are only successive stages of the same growth. The granular tubercles constitute the earliest stage of the new growth. They are of the size of a millet-seed, round, of uniform size, are almost transparent, and are scattered through the lungs in great numbers. The miliary tubercles are the next stage. They are somewhat larger, of gray color, and semi-transparent. Their size varies from that of a millet-seed to a hemp-seed. They grow by intus-susception, and thus become united in groups. Before this union, however, a small, yellowish, opaque speck appears in the centre of each tubercle; this speck gradually enlarges, and finally involves the whole tubercle. After a certain time, the conversion of the whole into this yellow matter is completed, and the group then constitutes only a single homogeneous mass of a whitish yellow color, and of a texture somewhat less compact and moister than that of cartilage; it is then said to constitute crude tubercle.

Encysted tubercles are very rare. They are the result of inflammatory processes, causing thickening and softening around miliary tubercles.

The infiltrated tubercles he divides into two varieties, the gray and the yellow.

(1.) The gray infiltration is formed around excavations. We sometimes also find it existing primitively in cases where no tubercles exist, but this is rare. In other cases, we find tuberculous masses of a large size in the first or semi-transparent stage, without any previous development of miliary tubercles. These masses are dense, humid, impermeable to air, and of a gray color. They may after a time become yellow and soften.

(2.) The yellow infiltration is found in yellow masses of variable size. Sometimes it occupies a small portion of lung, sometimes nearly all of it. After a certain time, it is prone to soften, liquefy, and form caverns.

Laennec's descriptions were taken entirely from the gross appearance in the lungs, but in 1844 Lebert applied the microscope to the study of the lesions described by Laennec. He endeavored to find some anatomical element characteristic of tubercle. His

studies were principally directed to the yellow and infiltrated tubercle. Here he discovered the constant existence of certain bodies which he named "tubercle corpuscles." These he described as pale, spherical, irregular, or angular bodies, which are neither nuclei nor cells, and measure .005-.007 mm. in diameter. This seemed to complete the doctrine of phthisis and of tubercle. All phthisis was tubercular. The tubercles were not inflammatory products, but a new growth, and could be recognized by the presence of specific tubercle corpuscles. They occurred either as isolated nodules, or as larger infiltrations; in either case, they were first gray and then cheesy.

Such a simple and definite theory of the lesions of phthisis could not fail to find adherents; and as the cheesy tubercles are always the most conspicuous, all cheesy masses found in the lungs were generally called tubercular.

But convincing as this theory appeared, it found powerful opponents at the very outset. Broussais (1772-1838) taught that all the lesions described by Laennec as tubercular, were really the products of inflammation. Andral used the word tubercular as synonymous with cheesy, and from observing that pus may become cheesy, he regarded all tubercles as produced by the thickening of an exuded inflammatory product. The gray granulations he held not to be tubercles. Reinhardt, in 1847, taught that Lebert's tubercle corpuscles were nothing but shrivelled pus cells. He held that all the lesions of phthisis, whether isolated or infiltrated, gray or yellow, were always produced by inflammation, and were nothing but a form of pneumonia.

At about the same time, Virchow followed Reinhardt in teaching that all the infiltrated and cheesy lesions were not tubercular, but products of pneumonia, but he reserved the name of tubercle for the miliary granulations and regarded them as new growths of structure similar to that of the lymphatic glands.

Niemeyer applied these pathological studies to clinical teaching, and taught that phthisis is not necessarily tubercular, but that in many cases all the lesions are due to chronic pneumonia.

The views of Virchow and of Niemeyer rapidly gained ground, and the name of tubercle was more and more restricted to the miliary granulations, while all the infiltrated and cheesy masses were ascribed to chronic inflammation. More study, however, was given to the minute structure of the miliary tubercles. It was found that they consisted not merely of a mass of small cells, but of a fibrous reticulum, of large, polygonal nucleated cells, of small round cells, and of giant cells.

But the tide of medical opinion is now once more turning. In 1872 Buhl, of Munich, published his memoir on the lungs. With him most of the lesions of phthisis depend upon what he calls desquamative pneumonia. In desquamative pneumonia there is, he says, first an infiltration of the walls of the alveoli with a plastic fluid, at the same time a production of epithelial cells in the cavities of the alveoli, then, if the process continues, there is a production of new fibrous tissue between the air-cells and fatty degeneration of the new epithelial cells within them. As a variety of desquamative pneumonia, and produced from it, he describes cheesy pneumonia. In other words, he gives the name of desquamative pneumonia to a combination of the two conditions which I have described to you under the names of interstitial pneumonia and intra-alveolar chronic pneumonia.

Miliary tubercles he describes in the usual way, but deduces them from the same desquamative pneumo-

nia. Miliary tuberculosis of the lungs is, he says, a desquamative pneumonia, differing from the ordinary form only in this, that among the proliferating cells of the alveolar walls giant cells appear. The tubercle is thus first formed within the cavity of an air-vesicle, at a later period there is a local infection of the alveolar wall beneath, and miliary tubercles are developed there also. The lesions of chronic phthisis he ascribes partly to tubercles, partly to chronic desquamative and cheesy pneumonia, and partly to peribronchitis. Acute miliary tuberculosis is, he says, only a general pneumonia, accompanied by the formation of tubercles. The name of tuberculous pneumonia may be used as synonymous with cheesy pneumonia, for it is an inflammation which is necessarily accompanied with the formation of tubercles. He distinguishes, therefore, acute miliary tuberculosis as infectious phthisis, and chronic tuberculous or cheesy pneumonia as inflammatory phthisis.

In 1873 Wilson Fox read before the Pathological Society of London a paper on tubercle. He asserted that, in both acute miliary tuberculosis and chronic phthisis, in the small nodules and the large infiltrations, the same anatomical elements exist, namely, a reticulated connective tissue stroma enclosing rounded cells. This tissue, which he calls adenoid tissue, he considers the essential element of tubercles. For him, therefore, all phthisis is tubercular.

In 1875 Rindfleisch published a short monograph on tuberculosis.

He defines tubercle to be a small, circumscribed form of scrofulous inflammation. The miliary tubercles are first formed at the points where the terminal bronchioles are continuous with the acini of the lung. A tuberculous infiltration of all the angles and projections which exist at the junctions of the terminal bronchioles and the lung acini is the first act of the morbid change, and leads to the formation of circumscribed nodules or tubercular granulations.

The appearance of these granulations is preceded and accompanied by catarrhal inflammation of the bronchi.

The next step is a tubercular infiltration of the walls of the bronchi, an ulceration of their mucous membrane, and a chronic, scrofulous, cheesy pneumonia. The infiltration of the bronchi is effected by a propagation of the tuberculosis in the peribronchial lymphatic vessels, and is accompanied by a production of new connective tissue. The scrofulous pneumonia he describes in the same way as Buhl does his desquamative pneumonia. He deduces from it in the same way the new interstitial fibrous tissue, and the filling of the air-vesicles with epithelial cells.

He believes that the invasion of miliary tubercles is like that of malignant tumors—1. A local scrofulous inflammation; 2. Tuberculosis of the lymphatic glands; 3. General tuberculosis.

He defines scrofula as follows: "A peculiar course of all the inflammatory processes which occur in certain persons, is the characteristic mark of a constitutional disease which we call scrofula."

You may perhaps have been confused by hearing all these different views. Let us consider for a moment how much progress has been made in our knowledge of tubercles and of phthisis.

Laennec first clearly described and grouped together all the lesions of acute and chronic phthisis. It is not surprising that, without the help of the microscope, he should have regarded all these lesions as accidental products of the same nature.

Lebert, in describing specific tubercular corpuscles.

committed an error, pardonable in the early days of microscopy, and long since renounced by himself.

Reinhardt and Virchow drew attention to the distinction between acute miliary tuberculosis and the lesions of chronic phthisis. They also demonstrated that cheesy degeneration is not peculiar to tubercle, but occurs in any inflammatory product.

By the labors of Langhaus, Wagner, Schüppel, and others, we know what is the minute structure of miliary tubercle.

Finally, Buhl, Wilson, Fox, and Rindfleisch, although in different ways, have all labored to prove that the anatomy of miliary tubercles, and of part of the lesions of phthisis, is essentially the same; that the lesions of chronic phthisis are made up of a combination of tubercular and inflammatory products, and that tuberculosis is itself a species of inflammation.

By the labors of all these different investigators we have, therefore, made substantial progress, if not in theory, certainly in facts. The most valuable result of all their studies has been, not any complete theory which will explain all the phenomena of tuberculosis, but a more exact knowledge of what these lesions are. And this seems to me to be a matter of much more consequence. To ascertain the exact structure of the lesions of acute and of chronic phthisis is a much more profitable task than to speculate concerning their origin and relationships.

Let us then consider for ourselves what lesions exist in the lungs of persons who have died of phthisis. We cannot help seeing that, clinically, acute miliary tuberculosis is an entirely different disease from chronic phthisis.

Here, for example, is a case of acute tuberculosis: Adolph W., 54, German, was admitted to the Roosevelt Hospital Nov. 20, 1874. Three weeks before his admission he was attacked with chilliness, headache, fever, pain in the epigastrium, vomiting, and epistaxis. His bowels were constipated until six days ago, when he took purgative medicine; since that time they have been loose. During the last week he has had a slight cough, with scanty expectoration. During the last four days he has been delirious.

When admitted to the hospital he was pale and weak, tongue coated, bowels loose, and was supposed to have typhoid fever. Nov. 26 there was partial paralysis of the right arm and leg.

Nov. 28, died.

At the autopsy the only lesions were large numbers of miliary tubercles in the pia mater, in the lungs, in the liver, in the spleen, and in the kidneys.

Here was a patient sick only for four weeks, with marked constitutional disturbance, rapid sinking into a typhoid condition, and with no symptoms of lung disease. At the autopsy, the brain, lungs, liver, spleen, and kidneys were found to be studded with small, grayish granulations—miliary tubercles. Nothing could seem to give a clearer picture of a general rather than a local disease.

If we examine these little granulations, such as were found in this man's viscera, what do we find? We find that they are small, rounded nodules, composed of a basement substance and cells. The basement substance is partly reticulated connective tissue, partly a diffuse, finely granular substance. The cells are, 1st, one or two large, rounded, finely granular masses, containing several nuclei, situated sometimes at the centre, sometimes near the periphery of the nodules; 2d, large, polygonal, nucleated cells, looking like epithelial cells; 3d, small, round, and oval cells, like the cells found in any new or inflamed connective tissue. In some of these nodules the central portions

were changed into a finely granular structureless mass; in some the stroma was so abundant as to look like fibrous tissue. The same reticulated connective tissue was found, not in nodules, but as an irregular infiltration between the air-vesicles. Within the adjacent air-vesicles we find products of inflammation—fibrine and epithelial cells. In the bronchi there were evidences of catarrhal inflammation.

I have given you in this case a distinct clinical history, and a distinct set of lesions. That there is a disease characterized by such symptoms and such lesions is agreed by all; it is called acute miliary tubercles by all; and nearly all give a description of the lesions substantially the same as that which I have given you. So much then you may regard as settled. The points yet undecided are as follows:

1. Is such a miliary tuberculosis always due to infection from a pre-existing cheesy focus?
2. Are these miliary tubercles an inflammatory product, or a new growth?
3. Are they identical in character with any of the lesions of chronic phthisis?
4. Where and from what are these miliary tubercles developed? Are they formed within the air-cells, or in their walls, or in the walls of the blood-vessels, or the bronchi, or within the lymphatics? What are the giant cells, and the epithelial-looking cells contained in the tubercles, and from what are they formed?

All these are questions still open for study and discussion, and concerning which great differences of opinion exist.

Now let us turn to quite a different picture—the symptoms and lesions of chronic phthisis. With the clinical history of this disease we are only too familiar. It begins either insidiously, or with an acute attack, and then runs a course lasting for months or years. Sometimes the patients recover; sometimes they recover for a time, and then are again attacked; sometimes the progress of the disease is steady and continuous. The symptoms point to a local affection of the lungs. Cough, expectoration, pain in the chest, dyspnoea, hæmoptysis, fever, emaciation, and loss of strength, with the physical signs of lesions in the lungs, are the regular attendants of the disease.

After death we find marked changes in the lungs. The pleura is thickened and adherent. The bronchi exhibit the lesions of chronic inflammation. The lung tissue contains bands, patches, and nodules, looking like fibrous tissue; cheesy nodules of various sizes; red, gray, or gelatinous hepatization of large or small portions of lung; frequently cavities which usually communicate with the bronchi. According to the extent and relative amount of these lesions, the lungs will vary in their appearance. In some cases the cheesy masses, in others the fibrous tissue, in others the red or gray hepatization, in others the cavities will attract our attention. In New York the prevailing form seems to be that in which fibrous tissue, cavities, and small fibrous and cheesy nodules are the predominant lesion.

If we examine these lesions with the microscope what do we find? We find three things. The air-cells are filled with epithelial cells and fibrine, and these cells and fibrine may undergo cheesy degeneration. Between the air-cells is reticulated and fibrillated connective tissue; portions of this have the same appearance as the miliary tubercles, the same stroma, the same large and small cells, and the same giant cells. But they also resemble in their structure the new connective tissue produced by inflammation in other organs. We find similar tissue in white swelling of the knee-joint, in cirrhosis of the liver, in chronic diffuse nephritis, in the granulation tissue of chronic

ulcers of the skin, and in other situations. While, therefore, we must admit that in chronic phthisis one of the regular lesions is a diffuse production of new tissue similar to the tissue of miliary tubercles, we must also admit that it is a tissue similar to that produced in other chronic inflammations. Whether tubercular or not, it certainly seems to be a product of chronic inflammation, and to this conclusion tend the studies of all observers.

We may, therefore, leave as open questions: 1. What is the relationship between acute tuberculosis and chronic phthisis? 2. Are the lesions of chronic phthisis simply inflammatory, or is the inflammation accompanied by the production of tubercles? 3. Are the chronic inflammatory processes preceded by, accompanied with, followed by, or are they the same thing as miliary tubercles?

But, in spite of all these undecided questions, we may rest fairly on these conclusions: 1. There is a disease called acute tuberculosis, with the symptoms of an acute general disease, and as lesions the production of miliary tubercles, not merely in the lungs, but throughout the body.

2. There is an affection of the lungs with the symptoms and lesions of chronic inflammation of those organs. These lesions consist essentially in the formation of new reticulated connective tissue between the air-vesicles, and of epithelium and fibrine within them. The new tissue between the air-cells resembles the tissue of miliary tubercles. Both the new tissue between the air-vesicles, and the epithelium and fibrine within them, may undergo cheesy degeneration.

Progress of Medical Science.

LARGE DOSES OF BROMIDE OF POTASSIUM IN THE TREATMENT OF EPILEPSY.—Very favorable results are reported from the use of this drug by Dr. Otto, who relates a series of thirty-three severe cases of epilepsy. Most of them had seizures daily, or oftener, and twenty-nine had also some form of mental disorder. In fourteen patients the attacks ceased from the day the medicine was given, and in most of them did not recur for eight months. In seventeen patients the attacks became less frequent, ceasing entirely in three of them when larger doses were given. In the rest the attacks were less frequent, intervals of six months occurring. One patient died six weeks after beginning treatment; in two, attacks recurred after the remedy was left off. The mental condition of all was much improved. Of the whole number four remained free from attacks, even after the medicine was stopped. Most of the patients easily bore 185 grains daily, and our author advises against exceeding 230 grains. In recent cases he gives about 150 grains daily, divided into four doses, adding a little opium if it produces diarrhœa. The long continuance of this quantity, however, or a gradually increased dose, produced disturbances in the sensorium and motor paralyzes, from which, however, the patients recovered completely when the remedy was discontinued. When used for two or three weeks skin lesions were always manifested, comprising acne, pustules resembling furuncles, and ultimately quite an extensive superficial ulceration of the skin. These, then, and the nervous lesions are the indications for discontinuing or diminishing the doses, for the disturbances of the alimentary canal can be overcome by giving it in sufficiently diluted solutions. The author considers the bromide the efficient ingredient of the

salt, as bromide of sodium and hydrobromic acid acted in the same way, while other potash preparations were without influence upon the disease. He believes that it acts by removing the irritability of the central ganglia and the peripheral nerves, and so averts the seizures.—*Archiv für Psychiatrie. Memorabilien*, April 8, 1875.

PURPURA HEMORRHAGICA TREATED BY HYPODERMIC INJECTION OF ERGOTINE.—Dr. Andrew K. Minich relates an interesting case of dangerous purpura hemorrhagica, occurring pretty suddenly in a child seven years old, who had previously been healthy. The case was treated successfully with hypodermic injections of ergotine. When the patient was first seen the condition was quite alarming; blood was issuing freely from nearly all the mucous orifices of the body, and there was bloody vomiting and profuse epistaxis; the parotid glands were infiltrated and swollen with blood, while large purple ecchymoses appeared underneath the skin. A grain of ergotine was injected hypodermically, and repeated twice within 24 hours, with the effect of completely arresting the hemorrhage, and in a few days the child was perfectly well.

The pathology of this malady is somewhat uncertain. Some have been disposed to attribute it to fatty degeneration of the capillary vessels. But the prompt action of ergot upon the affection, whatever its nature may be, could scarcely be explained on the above supposition. Minich suggests *vaso-motor paralysis*. Ergot produces *vaso-motor spasm*; thus "we have explained to us somewhat satisfactorily how it is that ergot will cure this affection."—*Phila. Med. Times*, May 8th, 1875.

CORPORA CAVERNOSA IN THE NOSE.—In the *Boston Medical and Surgical Journal* for April 29, Dr. Henry J. Bigelow calls attention to the existence of an erectile tissue upon the turbinated bones of the nose. This tissue is designated as "turbinated corpora cavernosa," not a particularly fortunate name, however, since we are not informed that the corpora cavernosa are turbinated, but simply that they are situated on turbinated bones. Some of the phenomena observed in acute nasal catarrh (popularly known as "cold in the head") are supposed to be owing to the erection of these cavernous bodies. The article is prefaced by six fine plates. Two of them are from Köhler's, a portion of whose minute description of the erectile tissue in the nose is quoted.

THE SIMULTANEOUS OCCURRENCE OF VALVULAR LESIONS AND PHTHISIS.—Dr. Ernst Frommolt, of Dresden, at the close of a statistical article, illustrated by a series of cases, thus sums up his conclusions on this subject: 1. The simultaneous occurrence of chronic valvular disease of the heart and phthisis is not by any means so rare as has hitherto been assumed. 2. Affections of the left arterial orifice are rather more frequently complicated with phthisis than those of the left venous orifice, although the difference is not marked. 3. Simultaneous affections of several of the orifices of the heart never, or very seldom, appear to be associated with phthisis.—*Archiv der Heilkunde*, April, 1875.

THE AMERICAN MEDICAL WEEKLY has clothed itself in a new garb, which is doubtless an indication of the success that has attended the enterprise. The editorial columns have been marked, since the start, by peculiar vigor and soundness on medical topics, while the letters from abroad have been particularly bright and instructive. The London correspondent is said to be one of the editors of the *Lancet*, and the news, therefore, comes from head-quarters.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, May 29, 1875.

THE PRESBYTERIAN HOSPITAL AFFAIR.

THE communication to the Trustees and Managers of the Presbyterian Hospital, which we publish in another column, brings up to the surface of discussion an important question concerning the rights of attending physicians and surgeons. For a long time the settlement of the proper relations of the managers of our public charities to their medical staff has seemed inevitable, but it has been delayed only for the want of a good opportunity which a test case would afford. Such an opportunity has at length occurred, which forces from the profession some expression of opinion in regard to its rights and privileges as servants of these institutions.

It appears from the circular before us that four reputable members of the medical staff of the hospital in question have been virtually dismissed, and that without any assignable cause. This is certainly a very high-handed proceeding, and deserves a thorough and impartial investigation, not only in the interests of the medical staff of the institution, but of the institution itself. It is absurd to suppose that any body of men such as that composing the board of trustees of this hospital should be guilty of any such action without what they supposed to be some good cause. This is the least that can be said to explain their course. We do not pretend to discuss their particular reason, whether the expelled members were in fault or not, but we do question the right of the managers to depose them as they have done without preferring any charge, without giving a chance for a defence.

If this right is allowed to go unquestioned, a very dangerous precedent will be established. No member of the staff will hereafter be safe in his position from one year to the other. In other words, the trustees will hold the good reputation of any medical man, who is so unfortunate as to place himself in their

power, in the hollow of their hands, and will be ready to damage such a reputation whenever, what they consider to be a sufficient excuse for so doing, presents itself.

It is, after all, not altogether the fault of the trustees of our public institutions that such a state of things exists. The profession is in no small degree responsible for it. The issue has been invited from the time medical men played the part of toadies to the appointing power. They have persuaded the trustees of hospitals and dispensaries that the positions on the medical staff were so valuable that they would do anything to gain them, in the first place, and retain them, in the second place. Under the circumstances, we can hardly blame these boards of hospital management for entertaining a becoming contempt for the profession at large, and applicants for hospital appointments in particular. We have forced them to believe that whatever they may do to any members of a hospital staff—slight them, insult them, dismiss them, or disgrace them—there are plenty of eager aspirants on file to fill the vacancies thus created. The truth of this is strikingly exemplified in the case of the Presbyterian Hospital. We do not mean it to be inferred that the new appointees abetted, directly or indirectly, the action of the managers by filling the vacancies of these four gentlemen; but we do say that, under the present circumstances, they occupy a far from pleasant position before the profession. Every one of the new members of the staff are gentlemen well qualified to hold the positions; but by continuing to do so they virtually support the trustees in an act of gross injustice to their deposed brethren.

The request in the circular referred to—to make the cause of dismissal of the gentlemen a subject of trial and a matter of publicity—appeals to every notion of fairness, policy, and ordinary justice. Signed by so many representative medical men, it has a significance which no board of trustees can afford to ignore. We very much regret that a body of honorable men, such as is the board of trustees of the hospital, should have so far forgotten its obligations as to allow any opportunity for questioning its motives, or for suspecting it of any other than plain dealing and gentlemanly treatment to men who were, by virtue of their position, in every way entitled to such considerations.

VIVISECTION.

A BILL has been introduced into the House of Lords, having for its object the restriction of vivisection to those cases in which it can be proved to be absolutely necessary. This, after all, is quite a reasonable way of striking a happy mean between the two extremes. The bill provides that physiological experiments shall only be performed upon animals at certain places which shall be duly registered and subject to inspection. This will prevent any wanton destruction of animal life by incapable but enthusiastic experi-

menters, and will limit the practice of vivisection to experts. On this point there cannot be much division of opinion. While its tendency is to diminish the sacrifice of animal life, it at the same time affords the best of opportunities for those researches in experimental physiology which are of peculiar value to scientific medicine.

On this general question of vivisection Sir Thomas Watson speaks for the profession of Great Britain, and his sentiments will have a sympathetic response on this side of the Atlantic. In a recent article in the *Contemporary Review*, he maintains that no one is justified in making any painful experiment on a living creature who does not possess the skill, judgment, intelligence, and previous knowledge necessary to render the experiment successful and instructive.

This, it strikes us, is a very satisfactory way of settling the difference between unintentional cruelty and scientific necessity, and should quiet the opposition of the different societies for the prevention of cruelty to animals which of late has been so unreasonable, bitter, and unjust.

THE NEW BUILDING FOR THE ACADEMY.

THE inauguration of the new building of the New York Academy of Medicine was an event in the history of the profession of this city not soon to be forgotten. The idea of a home for the profession of this city has long been cherished by this association, and now that their expectations have been realized in the possession of a handsomely furnished mansion, it is a matter of a great deal of congratulation. The presentation of portraits of the founders of the institution was an impressive endorsement of the labors of those who have been so untiring in their devotion to the interests of the Academy. We congratulate the Committee of Ways and Means on the results of their labors, and look upon the event of the medical teaparty as an inauguration of a revolution of medical affairs in this city. The Academy, by the efforts of its own membership, has secured by personal subscription its elegant home, and generously hopes that it may be used as a centre around which all the medical interests of this metropolis may gather. We doubt not that the profession at large will be willing to second any such endeavor.

MEDICAL ADVERTISING.

THE question of our correspondent, "Medicus," in regard to publication in a daily paper of the protest against the managers of the Presbyterian Hospital has a pertinent bearing upon the matter of medical advertising. We cannot believe that the publication was sanctioned by the gentlemen signing the document, but that it was the result of a mistaken policy and short-sighted enthusiasm of some one of the interested parties. Such documents are always out of place in a secular paper, and always tend to lower the profession in the estimation of the public.

MEDICAL LEGISLATION IN PENNSYLVANIA.

ANOTHER instance of the absurdity of medical legislation is afforded in the law recently passed by the Pennsylvania legislature. After specifying the essential qualifications for a practitioner of medicine, which are well enough so far as they go, exceptions are made in favor of those who have practised a certain time without a diploma; and of the numerous advertising quacks who are allowed to practise by the payment of two hundred dollars for a license.

In the eye of the law of Pennsylvania, if an incompetent man has practised a certain time he is entitled to protection equally with a well-educated medical gentleman, while the payment of two hundred dollars annually is a sufficient offset for a medical diploma. We should like to know what our medical brethren of Pennsylvania have gained by this law.

Reviews and Notices of Books.

CYCLOPEDIA OF THE PRACTICE OF MEDICINE. Vol. II. Acute Infectious Diseases. By DR. H. VON ZIEMSEN. American Editor, DR. A. H. BUCK. New York: W. WOOD & Co.

THE subject of the acute infectious diseases is concluded in this volume, which includes Varicella, Measles, Rubella, Scarlet Fever, Small-Pox, Erysipelas, Miliary Fever, Dengue, Influenza, Hay Fever, Malarial Diseases, and Epidemic Cerebro-Spinal Meningitis. The translators are Drs. James C. White, and Edward Wigglesworth, Jr., of Boston; Dr. Edward W. Schauffler, of Kansas City; and Drs. A. Brayton Ball, J. Haven Emerson, George H. Fox, Edward Frankel, and John C. Jay, Jr., of New York.

The first article is on Varicella, by Professor Thomas, of Leipsic. One of the points of especial interest to the reader will naturally be the position taken by the writer on the relation between this disease and variola, and his opinions will therefore coincide with those that are generally held both in this country and in Europe, when he opposes Hebra and his followers, who claim an identity for the two diseases. The distinction he makes is as follows: In varicella there is no increase in the temperature before the eruption; in variola it is marked for several days; varicella has vesicles and variola pustules; varicella is a disease of children; variola, of adults; vaccination affords no protection against varicella, but does against variola; variola sometimes follows almost immediately upon an attack of varicella, and varicella follows sometimes upon variola; while either one of the diseases once incurred affords almost entire protection against another attack.

Of the two articles, Measles, and Rubella, or German measles, the latter deserves attentive reading, as the writer elevates it to the character of a specific disease, distinguished, on the one hand, from the non-specific form of roseola, and on the other from measles and scarlet fever. This the author shows by the relation of certain epidemics, where the characteristics he describes were well marked. The exanthem is not at all like that of scarlet fever, while it differs from measles in that the maculæ are smaller, rounder, and paler, while there is absence of the bluish-red tint.

Scarlet fever is the most exhaustive article in the

book, covering 167 pages. It embodies the results of great literary industry, and bristles with an array of facts that is positively marvellous. The author advocates the symptomatic treatment as being the only rational one. The disease cannot be cut short or interrupted in its natural course, while it leads to recovery, provided the fever and local symptoms remain within certain bounds. Hydro-therapeutics are recommended in severe cases, as his experience has shown that they will moderate the fever, though they will not limit the duration of the disease or prevent complications.

Dr. Zuelzer, director of the Charité Hospital in Berlin, has contributed a number of interesting articles. Among the most noteworthy seems to be Erysipelas. As for the etiology of this disease, he calls attention to the numerous instances where the evidence points to the transference of the disease from one infected patient to another, and also enumerates instances where the disease arises idiopathically, as we term it, where none of the common causes of the disease could be inferred. A rather important point in the etiology of the disease he has neglected to mention. It is referred to by Steinberg in his report on the efficiency of the military hospitals in Berlin during the last war. That writer mentions that in one instance erysipelas broke out simultaneously at a number of detached hospitals of the city, and the occurrence was coincident with a sudden change in the temperature. A similar observation is also recorded by the same writer as having occurred during the war of 1866.

Miliary fever, or "the English sweating sickness," is stated to be a specific disease that has prevailed in epidemic form for hundreds of years, disappearing at times and again appearing, being at times quite mild, and at others a very fatal scourge. He therefore differs from Hebra and some other authorities, who believe that the miliary are accidental complications, due to excessive sweating in the various febrile affections, or are an artificial production. The two stages of the disease, that of sweating and of eruption, are carefully described.

Professor Hertz, of Amsterdam, contributes the article on Malarial Fever, which he has had an excellent opportunity of studying on the northern shores of Europe. We hardly expect that any foreigner can teach us much on this subject, but the reader will find in the article much that is both suggestive and instructive.

Dr. Von Ziemssen concludes the volume with an article on Cerebro-Spinal Meningitis. After giving a careful résumé of the subject, he observes that, as far as treatment is concerned, we have not yet learned all about the disease. We may favorably affect its course, but it is still a matter of question whether we can lower the death-rate.

Antiphlogistics, anti-pyretics, and narcotics are recommended, and of the latter he says that morphine may be regarded as one of the most indispensable remedies.

This volume well sustains the reputation of its predecessor, and displays, like it, a pretty thorough winnowing of all the foreign literature as well as of our own.

DR. BELL PETTIGREW, Lecturer on Physiology at Surgeon's Hall, Edinburgh, and lately a candidate for the Professorship of Physiology in the University of Edinburgh, has been awarded the Goddard Prize of the French Academy of Sciences, for his original anatomical and physiological memoir, and, in consequence, becomes a Laureate of the Institute of France.

Reports of Societies.

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Stated Meeting, April 26, 1875.

DR. H. B. SANDS, PRESIDENT, in the Chair.

DISCUSSION ON DR. CURTIS' PAPER (see page 369).

DR. E. R. SQUIBB, upon invitation, remarked, with regard to the discrepancy in the effects obtained by the administration of conium—and the same is true regarding the action of most neurotics—that when a temporary action is attained by a therapeutical agent, which is evanescent in its effect, the recurrence of the disease which takes place is *minus* a certain amount of habit, and although the substance administered may not be curative, its influence upon disease may be very important. He was of the opinion that, to a certain extent, we may theorize in this way with regard to the effect of quinine, in the cure of intermittent fevers, for example, and certainly so with regard to the effect of nitrite of amyl in the treatment of epilepsy. Dr. Kempster had informed him that, since the introduction of nitrite of amyl in the treatment of epilepsy, the epileptics in his wards, in the insane asylum at Oshkosh, Wis., have changed entirely. That is, whenever the aura is present the nitrite of amyl is given with the very first indication of its presence, and the attack is either aborted or prevented; and the subsequent recurrence of the epileptic attacks has been minus something of the habit.

This remark was thrown out as an observation upon the result that may be obtained by the administration of a remedy whose effect is evanescent. By aborting the habitual recurrence of epileptic attacks the patient may be very greatly benefited.

It was in this way, he thought, that we might account for the changed condition seen in the recurrence of blepharo spasms, and the same is probably true of those cases in which Dr. Harley has realized benefit by the use of this remedy, and sometimes cure has taken place. Reference is made to those cases where we have simple spasmodic action of the muscles.

Another point in the paper impressed him, and that was the very ingenious explanation of the effects of conium with regard to a similitude they give with sea-sickness.

We have most of the inebriating effects of conium in alcohol, but not often either giddiness or nausea. There is a giddiness, but not the giddiness described, and it is not accompanied by nausea. The giddiness and sickness of sea-sickness and from the effects of conium are of a peculiar nature, and the giddiness of alcohol is not similar to either.

With regard to the lack of uniformity in the strength of preparations of conium, he explained by saying that the conium fruit when green is much more potent in the presence of the active principle than when ripe. The analogy is very close to that of opium, for if an incision is made in a ripe poppy but little opium will be obtained, while in an unripe poppy, if an incision is made, an exudation takes place which contains the morphia elements. There is something in the growth of many of these plants which renders them very sensitive, and in order that a preparation may be made from them which shall have a uniform therapeutical strength, it is essential that they are gathered when the plant has attained a proper age. It was his impression

that animals may browse upon the hemlock plant when it is very young without any injurious effects, and also when the plants are old with the same immunity. The plant is also consumed as "greens" in some countries. Another requisite for making reliable preparations of conium is, to have the fruit collected and dried by skilled hands. Dr. Manlius Smith, of Syracuse, has, for several years, collected the fruit which he uses in making his preparations. The fruit must be collected when it is just ripe enough, and not over-ripe, and then dried with skill. When this is done, the only skill requisite is that which enables the pharmacist to obtain the active principle of the fruit without the aid of heat. The variations in the strength of the English *succus conii* arise from the fact that the plants have been collected in a wet season of the year in one case, and in a dry season in the other, the water present in the plant in the wet season accounting for the difference. The *succi* preparation can never be very reliable. The only safe plan that can be followed for obtaining a preparation of conium which possesses a uniform strength is to study the character of the plant, so that the fruit can be collected at the proper season, just as the plant has reached its maximum activity, and then dried to such an extent as the atmosphere alone will allow it to dry, and no farther. The plants will then keep, and there is no great tendency in them to deteriorate, if kept in a dry state. His experience, now extending over nearly ten years, had led him to believe that the active principle is comparatively permanent in the plant when it is carefully dried and properly stored. With the introduction of moisture it deteriorates very rapidly, the same as does ergot and other articles which contain medicinal properties that are easily liberated.

Dr. C. R. AGNEW remarked that perhaps a few words with regard to the case of hemlock poisoning which had lately occurred in Brooklyn might be proper at this time, and especially with the view of throwing some light upon the nature of that case. The case was one of blepharo-facial spasm, which commenced some ten or twelve years ago in a slight neurosis. Motility in the eye gave the patient double vision, and there was probably slight paralysis of the internal rectus muscle. At that time there was slight spasm of the orbicular muscle, which was an annoyance, but not sufficient to justify any special treatment. After the lapse of eight or nine years, while crossing Broadway, he was knocked down by a truck and received an injury over the orbital ridge of the left eye, and then this extreme violent spasm began. He had seen blepharo-facial spasms in several instances, but had never seen a case where the grimaces were so intense as in this man. The eyes would remain closed for an hour or two, with the muscles of the face twitching in every possible direction. About eighteen months ago, at his suggestion, the case was seen by Brown-Sé-ward, who was of the opinion that there was present disease of cerebral origin, and that the patient could be benefited by treatment. To this he submitted at once, and was placed under the influence of several remedies, as morphine, belladonna, calabar bean, strychnia, atropine, white-hot iron applied over the brow and over the spine, and all without benefit. The doctor then divided the supra-orbital nerves, first one and then the other; he then made an incision down upon the left supra-orbital nerve and removed a portion, and subsequently removed a portion of right supra-orbital; and then a portion of the left trochlear, and afterwards a portion of the right, but all these operations, performed for the relief of the patient and done with the fidelity and ability which justly recommend the operator,

were followed by little or no effect upon the condition present. He then returned, at the suggestion of Dr. Brown-Séward, to his care. He now performed the operation of canthoplasty upon the left side, with a very slightly favorable effect, but it was only transient. It was then, at the suggestion of Prof. Curtis, made through Dr. Webster, that an attempt was made to bring the patient under the influence of conium. The preparation used was made from the leaves of the plant, and was administered in forty and sixty drop doses until 180 drops were taken between the hours of 10 A.M. and 11.45 A.M., but without producing any effect whatever.

He then went to Brooklyn, which of course required more or less of muscular effort, and later in the afternoon a preparation of conium made from the seeds was administered, and with the result now well known. The only point he wished to refer to especially was that the trouble unquestionably had a cerebral origin, because there was no inflammation of the eye or of any of its appendages. It is true that, after the blepharo-facial spasm had continued for some months, the conjunctiva of the lids and eyeball became more or less inflamed, as it always does under such conditions, but it was a secondary effect, and perhaps might be looked upon as reacting and becoming a cause, but it was not so in the beginning.

Dr. SQUIBB referred to the use of conium in other conditions than that which had been chiefly alluded to, and where, perhaps, it plays a more potent rôle as a remedial agent. He had seen a number of cases of cancer where the pain was relieved in a remarkable degree by dipping a piece of flannel or muslin in a reliable preparation of conium, exposing it to the air until the alcohol has passed off, and then placing it over the irritable, painful cancerous sore. Applied in this manner it affords relief so promptly as to leave no doubt but that it is due to the influence of the drug. When failure to obtain relief attended the use of the drug in this manner, he had attributed it to the fact that a poor preparation had been used. There is a preparation of conium, known as the New Haven preparation, which is supposed to be prepared by sun-drying the expressed juice of the plant, and then adding sufficient alcohol to preserve it. For a long time this was a preparation recognized for its reliability, but after a while it became a matter of speculative enterprise, and its reputation for reliability has been very nearly lost. In cases, therefore, where this preparation has failed to afford relief when applied locally, he had suggested the method of applying the drug which has just been alluded to.

Belladonna may be used in the same manner, and a piece of flannel dipped in the fluid extract of this drug and applied to the surface makes one of the most efficient belladonna plasters that can be used. In mucous membrane irritation, such as bronchitis, in that slow, senile character which this affection often assumes, it may be frequently used with great success. There are many other diseases and conditions where the efficacy of conium has been long recognized, and are perhaps the fields where the more legitimate benefits of the drug may be realized. The use of conium for the relief of toxical spasms is one of later days.

Dr. EMERSON mentioned a case of spasm affecting the left side of the body, involving the facial muscles, and there was present also, slight blepharo-spasm. He had given this patient a drachm of the preparation of conium, made after the formula of the British Pharmacopœia, having first tested its value upon himself, but no effect was produced. The second dose administered was one drachm and a half,

and the remedy was increased until the patient took five-drachm doses, and then the desired effect was produced. Four drachms modified the spasms somewhat, but they occurred again in about four hours; the dizziness, however, continued only about two hours. There was also muscular weakness and some sensation of nausea, and there was present another symptom which is uncommon, and that was hemorrhage. The menstrual flow, which had appeared at the time the first dose was administered, was very much increased, and the hemorrhagic tendency extended into the lungs, and she had hæmoptysis. The tendency to excessive hemorrhage was sufficient reason for stopping the remedy, and he would inquire of Dr. Curtis how this symptom was to be explained.

Dr. CURTIS replied that he had never met the symptom of hemorrhage following the administration of conium, and was not able to give any explanation for it, unless there is occasioned more or less paralysis of the vaso-motor function, producing organic changes in the blood-vessels; but in that event we should have flushing of the face, and as that does not occur, it is not probable that this is the true explanation. Such occurrences may be merely accidental.

Dr. EMERSON remarked that there was violent action of the heart and pain across the upper part of the chest after administering the largest doses.

Dr. MANLIUS SMITH, being invited to speak, reported a case where the patient, an inmate of State prison, took by mistake a tablespoonful of a reliable fluid extract of conium. In about two hours the doctor was summoned to see him, and found upon arrival that the man was unable to articulate, unable to open his eyes, and was perfectly limp. He at once administered $\frac{1}{2}$ of a grain of sulphate of strychnia hypodermically, and in about ten minutes he opened his eyes and talked so as to be understood. He was then raised upon his feet, but was unable to stand, and sank upon the floor. He was then carried to the hospital room and a mustard emetic was administered without producing much effect. He remained under the effects of the drug until the next day, about twenty-four hours after he had taken the dose, was sleepy, etc., but in the afternoon, four or six hours later, the effects had all disappeared. The case was mentioned chiefly for the purpose of calling attention to the hypodermic use of strychnia as an antidote in cases of conium poisoning.

Dr. AGNEW called attention to another fact, namely, the comparative worthlessness of minim glasses sold in the shops. He had received two of these glasses from importers, who had supposed them to be standard, but he had found, upon testing them, that they varied six drops in their capacity below the twenty-five minim line. It is important to know that the minim glasses, both those which are imported and those manufactured in this country, are unreliable.

Correspondence.

MEDICAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR,—I have read with pleasure your editorials on the subject of advertising doctors. I hope that you will continue them, and not fear to hold up to professional censure those of our brethren who seem to disregard the Code of Ethics. I would like to ask whether the advertising in the *Tribune* of the protest

by sixty members of our profession against the recent action of the Board of Managers of the Presbyterian Hospital, be not a violation of the Code? Four of the physicians were dropped for cause, and the managers feel themselves fully justified in their conduct. The medical journals of this city, are the proper channels of communication with the profession, and not the *Tribune* newspaper. You must have observed that each of these sixty names were paraded before the public, with a title appended. Let us have your opinion in this matter. MEDICUS.

WHISKEY AND SULPHATE OF MAGNESIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Will you please inform me through THE RECORD what reaction, if any, takes place, and what new substance is formed, if any, when you resort to the following experiment? Take of Epsom salts, 2 oz.; water, q. s. to dissolve the same; add 1 pint Bourbon whiskey. After the mixture stands for a few hours the bottle is filled with a complete jelly instead of a liquid. Please explain the phenomenon.

A SUBSCRIBER.

[The reaction you refer to is the normal one. Alcohol has the property of precipitating the sulphates, and in this case the precipitate has a gelatinous appearance from the fact that the sulphate of magnesia has the effect of taking up a large percentage of water in crystallizing. Under the microscope the gelatinous substance will be found composed of a mass of crystals of the sulphate of magnesia.—Ed.]

New Instruments.

A NEW INSTRUMENT FOR AMPUTATION OF THE CERVIX UTERI.

By C. FREDERICK CLARK, M.D.,

OF BROOKLYN.

For the purpose of amputating the cervix uteri, and at the same time divesting the operation of its great danger, hemorrhage, I had constructed for my use, by the Messrs. Tiemann, of New York, a pair of tooth-edged cutting scissors on the principle proposed by Dr. Richardson, of London, but so modified as to be available in uterine surgery.

The accompanying cut will sufficiently explain the instrument. The handle is curved on the flat so as to leave abundant space for working the blades while the speculum and tenaculum are in position, and the crossing of the blades in the handle renders the instrument easy of management, even when some forms of the bivalve speculum are used.

The cutting should be done slowly and firmly, thereby allowing each surface of the angular teeth to press on the tissues. If necessary, torsion may be used before fully closing the blades.

On the 9th of March I used the instrument to amputate the cervix, the case being one of conoid cervix, accompanied with dysmenorrhœa and sterility. The operation was performed without bilateral splitting of the cervix, and the stump was left to heal by granulation. *No hemorrhage* ensued, and the operation was in every way successful.

A tampon of cotton, moistened with a solution of carbolic acid and glycerine, was then applied to the wound, and, being removed the following day, showed a perfectly clean surface in process of healing.

Injections of a solution of carbolic acid were continued for ten days, at the expiration of which time my patient had entirely recovered.

As I believe this is the first case in which amputation of the cervix has been performed by this method, in view of its efficiency in my own hands, I am pleased to subject it to the judgment of the profession.

306 UNION STREET.

HASSENSTEIN'S OTOSCOPE.

IMPROVED BY GEO. TIEMANN & CO.

This instrument for examining the ear both with solar and artificial light consists of a brass tube, the one extremity to hold alternately one of three different sizes of ear specula, 1, 2, 3, whilst the other is provided with a glass lens adjusted to proper focal distance for examination. An opening has been cut into the tube and a highly polished nickel plated mirror, with a central perforation, placed within, at an angle of 45°. From this mirror the rays of light are reflected on to the part to be examined, which will be exactly at the extremity of the respective speculum.

The original instrument was made of hard rubber, very clumsy and fragile. The present instruments are constructed by Messrs. Tiemann & Co. entirely of metal, the tube blackened like a telescope, the specula silver plated, white inside, highly polished outside. The instrument is very light, and yet very durable.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from May 16th to May 22d, 1875.

HAMMOND, J. F., Surgeon.—To report to the Commanding General, Mil. Division of the Atlantic, for duty as Attending Surgeon, relieving Surgeon Bill. S. O. 92, A. G. O., May 17, 1875.

BYRNE, C. C., Surgeon.—Assigned to duty as Post-Surgeon at Fort Abraham Lincoln, D. T. S. O. 88, Department of Dakota, May 18, 1875.

WEEDS, J. F., Surgeon.—When relieved by Surgeon Byrne, to comply with S. O. 75, c. s., A. G. O. S. O. 88, c. s., Department of Dakota.

WOLVERTON, W. D., Assistant Surgeon.—Assigned to duty at Fort Abercrombie, D. T. S. O. 87, Department of Dakota, May 15, 1875.

KNICKERBOCKER, B., Assistant Surgeon.—Assigned to duty as Post Surgeon at Fort Culville, W. T. S. O. 53, Department of the Columbia, May 7, 1875.

BROWN, J. M., Assistant Surgeon.—Leave of absence extended 23 days. S. O. 97, Mil. Division of the Atlantic, May 17, 1875.

BROOKE, JNO., Assistant Surgeon.—Relieved from duty in Department of the Columbia, to proceed to Philadelphia, Pa., and, upon arrival, report by letter to the Surgeon-General. S. O. 92, c. s., A. G. O.

KINSMAN, J. H., Assistant Surgeon.—Assigned to duty at Fort Ripley, Minn. S. O. 83, Department of Dakota, May 11, 1875.

STEINMETZ, WM. R., Assistant Surgeon.—Relieved from temporary duty at Fort Melleny, Md., to report to the President of the Army Medical Board, New York City, for examination for promotion, and, upon its completion, to the Commanding General, Department of the Missouri, for assignment to duty. S. O. 92, c. s., A. G. O.

Medical Items and News.

DR. MONTROSE A. Pallen has been made "Professor of Gynecology" in the Medical Department of the University of New York, in lieu of "Lecturer on the Surgical Diseases of Women."

THE PRESBYTERIAN HOSPITAL AFFAIR.—The following communication regarding the recent trouble in the Presbyterian Hospital will sufficiently explain itself:—

NEW YORK, May 15, 1875.

To the Managers of the Presbyterian Hospital:

GENTLEMEN:—We, the undersigned Members of the Medical Profession in New York, have learned, with deep regret, the late action of your Board, whereby you have dismissed from your Hospital four Members of the Visiting Staff, without assigning any ground for such a course. So far as is known these gentlemen were fully competent for the positions which they held, and discharged their duties with diligence and skill.

We believe that you have failed to realize the full character of your action. In summarily discharging these gentlemen, you, in effect, proclaim your opinion that they are unfit for the positions which they held. By so doing you incur the responsibility of seriously injuring their reputation; and you have taken this grave step without preferring any charge, or assigning any reasons for so doing.

We believe you will admit that while you have acquired certain rights in assuming the position of Managers of a Hospital, you have also incurred certain obligations. While it is your right to appoint and dismiss the Medical Staff, it is also your duty to exercise this right for the best interests of the Hospital.

It is evidently your duty to obtain for the patients under your charge, the best medical and surgical skill which our profession affords. We can hardly believe that any physician or surgeon of reputation will serve in an institution from which he is liable to be dismissed without just grounds.

We believe, therefore, that, both as members of the medical profession and as citizens, we are justified in asking that you shall make public the reasons for your late action. If these gentlemen have in any way shown themselves unfit for their positions, let the facts be made known. If they have been discharged simply from caprice, they have a right to demand that this should be made as public as their dismissal.

We have the honor to be, very respectfully, your obedient servants—

Abram DuBois, M.D., Consulting Surg., N. Y. Eye and Ear Infirmary.

T. M. Markoe, M.D., Prof. Surgery, Coll. of Phys. and Surgeons.

Frank H. Hamilton, M.D., Surgeon to Bellevue Hospital.

Il. B. Sands, M.D., Prof. of Anat., Coll. of Phys. and Surgeons.

James W. McLane, M.D., Adj. Prof. Obstet., Coll. Phys. and Surg.

Francis Delafield, M.D., Physician to Bellevue, etc. John T. Metcalfe, M.D., Consulting Phys. to Roosevelt Hospital.

T. Gaillard Thomas, M.D., Prof. Obstet., Coll. Phys. and Surgeons.

Wm. H. Van Buren, M.D., Consulting Surgeon to Bellevue Hospital.

James R. Wood, M.D., Surgeon, Bellevue Hospital, etc.

Woolsey Johnson, M.D., Surgeon, N. Y. Eye and Ear Infirmary.

I. L. Little, M.D., Surgeon, St. Luke's Hospital.

Wm. H. Thomson, M.D., Physician, Bellevue and Roosevelt Hospitals.

Erskine Mason, M.D., Surgeon, Bellevue and Roosevelt Hospitals.

Austin Flint, M.D., Physician, Bellevue Hospital.

David Magie, M.D., Registrar, New York Hospital.

C. R. Agnew, M.D., Surgeon, Manhattan Eye and Ear Hospital.

Wm. T. Lusk, M.D., Prof. of Obstet., Bellevue Hospital Med. Coll.

D. B. St. John Roosa, Prof. of Eye and Ear, University of City of N. Y.

Thos. Addis Emmet, Surgeon, Woman's Hospital of State of N. Y.

Fordyce Barker, M.D., Obstet. Physician, Bellevue Hospital.

Henry C. Eno, M.D., Surgeon, New York Eye and Ear Infirmary.

Chas. P. Russell, M.D., Health Department.

Chas. E. Hackley, M.D., Physician to New York Hospital.

I. I. Hull, M.D., Physician to Nursery and Child's Hospital.

F. N. Otis, M.D., Surgeon, Charity Hospital.

A. Jacobi, M.D., Physician to Mt. Sinai, Bellevue, and German Hospitals.

Robert Watts, M.D., Physician to Roosevelt and Charity Hospitals.

John G. Curtis, M.D., Lecturer Adjunct, Coll. of Phys. and Surgeons.

Fredk. R. Sturgis, Surgeon to Charity and Manhattan Eye and Ear Hospital.

Henry F. Walker, M.D., Physician to Bellevue Hospital.

W. M. Polk, M.D., Physician to Bellevue Hospital.

Thomas T. Sabine, M.D., Surgeon to St. Luke's Hospital, etc.

Hermann Althof, M.D., N. Y. Eye and Ear Infirmary and German Hospital.

F. P. Kinnicutt, M.D., Physician, Out-Door Dept., Bellevue.

Robt. F. Weir, M.D., Surgeon, Roosevelt Hospital.

Edw. G. Loring, M.D., Surgeon, N. Y. Eye and Ear Infirmary.

Andrew H. Smith, M.D., Physician, St. Luke's Hospital.

Bache M. Emmet, M.D., Asst. Surgeon, Woman's Hospital.

W. H. Draper, M.D., Physician to New York and Roosevelt Hospitals.

Monis J. Asch, M.D., Physician to Metropolitan Throat Hospital.

Henry D. Noyes, M.D., Surgeon to N. Y. Eye and Ear Infirmary.

Clinton Wagner, M.D., Physician, Metropolitan Throat Hospital.

J. L. Campbell, M.D., Physician, N. Y. Orphan Asylum.

Ernst Krackowizer, M.D., Surgeon, N. Y., Mt. Sinai, and German Hospitals.

J. P. P. White, M.D., Surgeon to Charity Hospital.

W. R. Gillette, M.D., Physician to Charity Hospital.

Alfred L. Loomis, M.D., Physician to Bellevue Hospital.

Edward G. Janeway, M.D., Physician to Bellevue Hospital.

Chas. Mc. Burney, Jr., M.D., Surgeon to St. Luke's Hospital.

Austin Flint, Jr., M.D., Prof. of Physiol., Bellevue Hospital, Med. Coll.

J. W. S. Gouley, M.D., Surgeon to Bellevue Hospital.

Edward Curtis, M.D., Surgeon, N. Y. Eye and Ear Infirmary.

Charles Laight, M.D., Surgeon, N. Y. Eye and Ear Infirmary.

Freeman J. Bumstead, M.D., Surgeon to Charity Hospital.

George M. Lefferts, M.D., Surgeon to N. Y. Eye and Ear Infirmary.

W. Cockcroft, M.D., 59 West 45th St.

Stuyvesant F. Morris, M.D., Surgeon, New York Dispensary.

J. S. Thebaud, M.D., Surgeon to the Colored Hospital.

J. C. Jay, Jr., M.D., Physician to Children's Dispensary, etc.

Richard H. Derby, M.D., Surgeon, N. Y. Eye and Ear Infirmary.

Beverley Robinson, M.D., Surgeon, Manhattan Eye and Ear Hospital.

E. R. Peaslee, M.D., Prof. Bellevue Hospital Medical Coll., Physician, Woman's Hospital, etc.

DR. BURGGRAEVE, Emeritus Professor in the University of Ghent, is about to publish, under the patronage of the kings of Belgium, Sweden, Holland, and Italy, and the emperors of Russia, Austria, and Brazil, a work entitled; "*Histoire Générale de la Vaccine; ou, Monument à Edvard Jenner, à l'occasion du premier centenaire de son invention.*" It is to be published in Paris, by subscription, at a price of thirty francs.

THE PENNSYLVANIA ACT to regulate the practice of Medicine, Surgery and Obstetrics has passed the Legislature and received the signature of the Governor. The law specifies that the essential qualifications for a practitioner of medicine shall be "a comprehensive and practical knowledge of human anatomy, human physiology, pathology, chemistry, materia medica, obstetrics, practice of medicine and surgery, and public hygiene, and a good moral character." The possession of a regular diploma is to constitute a sufficient license to practice, provided it has not been obtained by purchase solely. Persons without diplomas are to be examined by a board to be appointed by the Court of Common Pleas, and to consist of three members, who are to receive five dollars each from each candidate examined. Exceptions are made in the case of persons who have been for a stated time in practice without diplomas; and transient, advertising physicians are required to pay two hundred dollars annually for a license.

RETIRING ROOMS FOR LADIES.—A company has been started in London to provide retiring rooms for ladies.

THE PUBLIC SCHOOL BUILDINGS of Philadelphia have been pronounced to be wretchedly ventilated, and defective in almost every other sanitary provision.

MR. G. W. CALLENDER, F.R.S.—It is reported that this London surgeon contemplates a visit to the United States during the latter part of the coming summer.

THE HAHNEMANN HOSPITAL.—By virtue of an act of the Legislature, signed by the Governor on March 20, the Homeopathic Surgical Hospital and the Hahnemann Hospital were consolidated under the above title. The Association have possession of ten lots on Sixty-ninth Street and Lexington Avenue.

A LARGE BRAIN.—The *Cincinnati Gazette* mentions that Wm. Boswell, a blacksmith, who died suddenly in an Indianapolis saloon a short time since, from excessive abuse of alcohol, had a brain weighing sixty-one ounces. His entire weight was over three hundred pounds. The degree of his mental development is not mentioned.

THE COLORADO TERRITORIAL MEDICAL SOCIETY will hold its fifth annual session in Denver, commencing Wednesday, 9th of June, and may continue three days.

A QUACK DOCTOR in Manchester, named Thomas Hoop, has lately been hung for causing the death of a young woman, upon whom he operated for the production of an abortion.

THE MEDICAL DEPARTMENT of the University of the City of New York have broken ground on East Twenty-Sixth Street for a new college building. The new building is to be directly opposite the entrance gate of Bellevue Hospital, and is to be very much larger than the one used by them for several years past.

DR. DANIEL H. KITCHEN, Chief of Staff of the Charity Hospital, has resigned his position.

THE INDIANA STATE MEDICAL SOCIETY is to meet on the third Tuesday of this month, and an effort is being made to organize throughout the State county societies, to be represented in the State society in a manner similar to our own.

PROFESSOR CHEEVER, of the Medical Faculty of the Michigan University, has returned from his two years' residence in Colorado, in a much improved condition of health, and is expected to resume his duties, which, in his absence, have been discharged by Professor Gerish, of Bowdoin College.

CANINE SAGACITY.—The *Medical Times* has another letter narrating instances of canine sagacity; this time from Walter F. Atlee.

"DEAR SIR:—In a letter recently received from Lancaster, where my father resides, it is said:

"A queer thing occurred just now. Father was in the office, and heard a dog yelping outside the door; he paid no attention until a second and louder yelp was heard, when he opened it, and found a little brown dog standing on the step upon three legs. He brought him in, and, on examining the fourth leg, found a pin sticking in it. He drew out the pin, and the dog ran away again.

"The office of my father, Dr. Atlee, is not directly on the street, but stands back, having in front of it, some six feet, a stone wall with a gate. I will add that it

has not been possible to discover anything more about this dog.

"This story reminds me of something similar that occurred to me while studying medicine in this same office nearly thirty years ago. A man named Cosgrove, the keeper of a low tavern near the railroad station, had his arm broken, and came many times to the office to have the dressings arranged. He was always accompanied by a large, most ferocious-looking bulldog, that watched me most attentively, and most unpleasantly to me, while bandaging his master's arm. A few weeks after Cosgrove's case was discharged, I heard a noise at the office-door as if some animal was pawing it, and, on opening it, saw there this huge bulldog, accompanied by another dog that held up one of its front legs, evidently broken. They entered the office; I cut several pieces of wood and fastened them firmly to the leg with adhesive plaster, after straightening the limb. They left immediately. The dog that came with Cosgrove's dog I never saw before nor since."

"LES ANNALES DES MALADIES DE L'ORIELLE ET DU LARYNX," is the name of a new journal to be published bi-monthly in Paris. MM. Ladreit, de Lacharrière, Isambert, and Krishaber are to be the editors, and G. Masson the publisher. Price twelve francs per year.

THE WISDOM OF PROVIDENCE IN THE ALLOTMENT OF DISEASE.—Mark Twain describes chills and fever as a merciful provision of an all-wise Providence, to enable people to take exercise without exertion.

THE EUCALYPTUS IN ITALY.—It is reported that the Italian Government, following the course it has already adopted on previous occasions, will gratuitously distribute this year five thousand plants of the *Eucalyptus globulus*, for cultivation in the Agro Romano.

OVARIOTOMY UNDER NUMEROUS DIFFICULTIES.—The *Tribune Médicale* tells of a Dr. S. G. Stevens, who, travelling in Central America, without other instruments than such as were contained in his pocket-case, performed ovariotomy successfully. A trocar was extemporized from a piece of bamboo, the pedicle was ligated with hair, and the abdominal cavity, after being cleansed with wadding, was closed with iron wire. A missionary administered chloroform, and was his only assistant.

THE AMERICAN PHARMACEUTICAL ASSOCIATION is to hold its next meeting in Boston, commencing on the 7th of September. The Boston druggists have raised about \$7,000 to defray the expenses of the entertainment of the visitors. Among other amusements proposed are a reception and banquet at the St. James Hotel, a concert at the Music Hall, and an excursion in the harbor.

DR. FOSTER SWIFT, formerly of this city, died on the 10th of May, at St. Croix, West Indies.

Thursday, June 3.—N. Y. Academy of Medicine.

Friday, June 4.—Medical Library and Journal Assoc.

Original Communications.

VOCAL FREMITUS IN PLEURISY AND PNEUMONIA, AND THE USE OF THE HYPODERMIC SYRINGE IN THEIR DIAGNOSIS.

By E. G. JANEWAY, M.D.,

NEW YORK.

THE value of vocal fremitus as a physical sign in the diagnosis of pleurisy, with effusion from pneumonia, is, it seems to me, not infrequently rated too highly. Some, in fact, appear to consider it an absolute means of distinguishing the one from the other condition. My reasons for not esteeming it as much as those who hold this opinion, are based upon the observation of cases in which such a belief would have been or proved to be a mistake. Let me first give a brief record of two cases of pleurisy with effusion, in which vocal fremitus was present over the affected portion. The first of these was a male patient in Ward 8 of Bellevue Hospital last summer (Simms), age 33.

He was taken sick two days before admission with rigors and a pain in the left side. When admitted the physical signs of interest were: Flatness on percussion on the right side of chest below the angle of the scapula, increase of vocal fremitus over the affected portion, feeble and distant respiratory sounds, ægophonic vocal resonance.

June 3d, two days later, distinct vocal fremitus was present over the affected portion, and a hypodermic syringe withdrew clear serum from the pleural sac at this part.

Aspiration of the affected side was performed several times, with only partial relief, and in consequence of obstruction of the needle, or failure of the apparatus, on two occasions but little fluid was obtained. After the second aspiration air was detected in the pleural cavity above the level of the remaining fluid, but below this vocal fremitus persisted. Later seropus and pus formed in the cavity, and it was decided to make an opening in the pleura, and allow the fluid to drain off. The reasons for the operation were the great dyspnoea, the existence of pus in the sac, the failure of aspiration to afford relief which was more than temporary, the increasing weakness of patient, and finally paroxysms during which the patient would pass almost into a state of collapse. The day following the incision vocal fremitus disappeared from the affected portion. On the 12th of November the patient was discharged. The second patient was a male fifty years of age, admitted to Bellevue Hospital on the 17th of November, 1874.

His illness had commenced one month before, with symptoms which pointed to the existence of pneumonia on the left side. When admitted he was thought to have a chronic pneumonia, or pleurisy with pneumonia of left lower lobe, extending into upper. Of this man I made a very careful examination about a week before his death. The following physical signs were then present: Flatness on percussion existed over the lower lobe of the left lung, except near its most anterior portion; here there was some resonance.

Bronchial voice, whisper, and respiratory murmur were heard over this part more distinct above, more distant and feebler below.

Measurement showed the two sides to be of equal size. The heart was not displaced, and vocal fremitus

existed over the affected portion, and was increased as compared with the opposite side.

There was no change of the level of flatness on percussion, and this line of flatness corresponded very closely to the interlobar division. The character of the bronchial breathing and voice made me suspect fluid, and so at my request the House Physician, Dr. Chapin, introduced the needle of a hypodermic syringe in the pleural sac, but failed to obtain any fluid. The hypodermic syringe seemed to be good, as tested by drawing up water from a tumbler. I then proposed bringing an aspirator on the succeeding day, for more thorough exploration, but the patient passed into a typhoid state, seeming to indicate the existence of meningitis as a complication. A post-mortem examination revealed the following: Dilatation of the ventricles of the brain with a granular condition of the ependyma, and empyema of the left side corresponding to the site of the left lower lobe, and shut in by adhesions of the upper lobe. A small portion of the anterior part of the lower lobe was adherent to chest, near heart, and the rest was carnified and pressed upwards, inwards and backwards.

The heart was not displaced. The lower part of the upper lobe of the left lung was hepatized. There was no adhesion of the lung over the space where I had perceived vocal fremitus; nor was any band-like adhesion, such as sometimes occurs, present.

These two cases, which have been observed within a period of eight months, are sufficient to show that vocal fremitus may be present over fluid in the pleural sac, and may even be exaggerated. The disappearance of the vocal fremitus in the one case after the removal of the fluid, and the results of the post-mortem examination in the other, show that the vocal fremitus was conducted through fluid to the chest wall.

In addition to these cases, I have observed two others during the same period, in one of which a slight vocal fremitus existed over fluid in the left pleural sac. This was enough to cause one physician to doubt the correctness of the diagnosis, though the left side was two inches larger than the right and the heart displaced. He, however, confessed when a hypodermic syringe drew fluid from this portion and an aspirator removed sixty ounces of serum.

In the other case the vocal fremitus was increased, but of this case I will make no use, as the patient escaped from my observation before I was able, satisfactorily, to determine the conditions present.

Again cases present themselves in which the vocal fremitus is exceedingly feeble or absent on the healthy side, and then the absence of this sign has no special value on the diseased side.

Such a case I have lately seen in a young man with rheumatic pericarditis and a small effusion in the left pleural sac. In this case vocal fremitus is absent at corresponding points on the two sides, but above the level of the fluid for a short distance it is considerably increased on the left or affected side: while at a corresponding point on the right side it is only feebly perceptible. Bronchial character of the expiratory sound is audible over the fluid and broncho-ægophony exists near its upper limit. I can very readily imagine that an incomplete examination might lead to the supposition of pneumonia. While I have been writing this article the fluid has accumulated somewhat on the right side also, but the vocal fremitus remains as at first. On the other hand cases have occurred in which pneumonia has been mistaken for pleurisy, with effusion, by very good observers. Some years ago I made the post-mortem examination in a case of

supposed pleuritic effusion. The autopsy revealed a small aneurism resting on the left main bronchus, and this completely occluded by a firm thrombus which had formed by the escape of blood from the aneurism into it by means of a small opening. The left lung was throughout in a state of gray hepatization, and its bronchi were filled with purulent fluid. Those who had seen this case, during life, stated that all the signs of pleuritic effusion had existed, absence of vocal fremitus, of respiratory murmur, of vocal resonance, with the existence of flatness on percussion. If any suspicion of the real condition of affairs had been entertained it seems probable that absence of displacement of the heart, and of increase of the measurement of the affected side might have corrected the diagnosis, considering the extent of disease. Since that time I have seen a second nearly identical case.

Again it sometimes happens that with ordinary pneumonia producing complete solidification of a lobe considerable diminution or absence of the vocal fremitus may occur.

Allow me in closing this short article, which is written in order to draw attention to the need of caution in the interpretation of physical signs, to urge the importance of attending to each physical sign in doubtful cases of these two diseases, and also of examining the symptoms presented by the patients, and the course which the disease takes. In doubtful cases, where, if fluid should exist, the line of treatment would be decidedly different, I think it wise to make use of an exploratory puncture. This may be done by means of a small needle attached to the aspirator, or, as this not infrequently alarms patients, at Bellevue Hospital a hypodermic syringe is often employed for this purpose. Considerable difference exists in the suction power of these instruments, and I have seen one introduced in a chest and fail to obtain fluid when another immediately afterwards succeeded. The safest test is not that of seeing whether water can be drawn through the needle into the barrel of the syringe; but, placing a finger over the nozzle, withdraw the piston and retain it in this position for a few seconds, and then note if the atmospheric pressure will force the piston back to its original position. With one, which answers perfectly to this test, I have succeeded in drawing pus from abscesses; and lately, in order to give it a fair test and also to relieve a patient, I employed it to remove thick gelatinous fluid from a ranula. This fluid was a little more viscid than the mucus of cervix uteri. If honest doubt existed after its use it would be wise to make use of an instrument with greater suction force.

Summary of the conditions of vocal fremitus in pleurisy and pneumonia:

1st. Vocal fremitus is usually absent over fluid in the pleural sac.

2d. When present (*a*) it is sometimes due to adhesions of the lung to the chest wall below the level of the liquid.

b. Again, it is sometimes conducted through the fluid, and then it may be either feebler or more intense than on the opposite side.

c. In some cases vocal fremitus does not exist or is very feeble at the lower part of the chest on the sound side; under these circumstances its absence on the diseased side loses some of its relative value.

3d. Vocal fremitus is usually increased over pneumonia of the lower lobe.

4th. It may, however, be very feeble or absent.

a. This may be due to obstruction of the bronchus by compression, or by the accumulation of some material in it, as, in one of the cases reported, coagulated blood.

b. Sometimes it seems due to the presence of a considerable amount of exudation in the pleural sac.

c. The amount of solidification is supposed at times to be the cause.

5th. Vocal fremitus is sometimes absent on the sound side; under such circumstances the existence of considerable vocal fremitus on the diseased would point strongly towards, though not be decisive of, pneumonia, as the morbid condition present.

My friend and colleague, Prof. Flint, is also in the habit of drawing attention to the greater value of absence of vocal fremitus on the right side as a sign of pleuritic effusion, and of its exaggeration on the left side as a sign of pneumonia, in view of the normal difference of vocal fremitus on the two sides.

It will be obvious, that in this article I have considered that the more important physical signs, percussion and auscultation, have pointed out the site of the disease, but have not been able to establish the diagnosis.

REPORT ON THE PROGRESS OF OTOLOGY.

By ALBERT H. BUCK, M.D.,

INSTRUCTOR IN OTOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS; AURAL SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY.

Read before the Medical Library and Journal Association, April 30, 1875.

MR. PRESIDENT AND GENTLEMEN:—In response to the polite invitation of your committee I have prepared a report on the Progress of Otolology during the past year. Two plans suggested themselves to my mind: either to prepare a thorough digest of all the published essays and works on otological subjects of the year, or simply to call your attention briefly to some of the more important ones—those which appear to me to be real and solid additions to our knowledge of the anatomy, physiology, pathology, and therapeutics of the ear. I have chosen the latter course, not only because I believe it will prove more interesting to you, but also because a very thorough and complete digest is furnished every year by a committee of the American Otological Society.

The chief difficulty I have encountered in preparing this report has been not the *dearth* of subjects to which I might call your attention, but rather the *superabundance* of really valuable contributions, by means of which otology has perhaps been more advanced during the year 1874 than during any previous one.

In the department of anatomy, I will first allude to the researches of Brunner, of Zurich:—

Gustav Brunner* contributes a very interesting and thorough paper on "The Connections between the Ossicles of Hearing." Not very long ago Rüdinger described the existence of a separate fibro-cartilaginous disk between the articular surfaces, not only of the incudo-stapedial, but also of the malleo-incudal joint. This meniscus, or interarticular cartilage of Rüdinger's, was compared to the semilunar cartilage that separates the articular surfaces of the knee-joint. On looking through the microscope at a thin section, made through one of these ossicular joints—the incudo-stapedial, for instance—I am sure that almost any ordinary observer would at once be disposed to agree with Rüdinger; the dark, well-defined line which bounds the so-called meniscus on either side, may very readily be taken for a line of separation,—the tissues on one side of it being separate and distinct from those on the other. Brunner has, however, resorted to the device of rupturing

* Archives of Ophthalmology and Otolology, vol. iii., No. 2.

the capsular ligament on one side of the specimen, while it lies upon the object-glass, and in this way he has demonstrated the fact, that this "boundary line is only the optical expression of the difference between the two forms of tissue," and not an actual dividing space, however thin. As regards the connections between the stirrup and the oval window, Brunner confirms the descriptions given by Eysell and other observers. He does not agree, however, with the statements made by Rüdinger regarding the existence of lacunæ in the connective tissue which separates the border of the foot-plate of the stirrup from the margin of the oval window. He is rather disposed to consider them as artificial products. In this view it seems to me that he is right, for if we remember how quickly an elastic tissue retracts, when its points of support have been taken from it, we can readily understand how these apparent lacunæ are created. The connective tissue lying between the articular cartilaginous surfaces of the ossicles retracts, after the razor has severed so many of its points of support, and as a result there is formed at this point a double depression, one on the upper surface of the section—I am imagining a section before me—and another on its under surface; in other words, the section being very thin, there is left at the point in question a minimum or even an entire absence of interarticular connective tissue, appearing to the eye like a lacuna.

The paper contains other interesting points, but we cannot allude to them in this brief report.

In the department of physiology I would call attention to the following contributions:—

Alfred M. Mayer, of the Stevens Institute of Technology in Hoboken, N. J., has written a valuable paper* entitled, "Researches in Acoustics." Among other things he gives an account of an experiment, by means of which he is able to analyze a composite sound. He thus describes it: "A loose, inelastic membrane (thin morocco leather does well) was mounted in a frame, and placed near a reed-pipe. The ends of several fine fibres from a silk-worm's cocoon were brought neatly together, and cemented to one and the same point of the membrane, while the other ends of these fibres were attached to tuning-forks (eight in all, in the present experiment) mounted on their resonant boxes." On sounding the reed-pipe—the tension of the communicating silk fibres having been first properly adjusted—the forks sang out in response to the vibrations of the membrane. The forks, it should be remembered, were selected with special reference to the fact that their respective tones were harmonics of the fundamental tones produced by the reed-pipe. Nevertheless, without the intervention of the tense communicating silk threads, these different forks would have remained silent. Mayer therefore concludes that "the point of the membrane to which the fibres are attached is actuated by a motion which is the resultant of all the elementary pendulum-vibrations existing in the composite sonorous wave, and the composite vibrations of this point are sent through each of the fibres to its respective fork. Thus each fibre transmits to its fork the same composite vibratory motion, while each fork can only vibrate so as to give the simple pendulum-vibration of a simple sound, for each fibre is attached to its fork at a point which lies in the upper node of the segments into which the fork divides when it gives its higher harmonic. . . . The fork will then select from the composite vibratory motion, which is transmitted to it, that motion which it has when it freely vibrates;

but if its proper vibration does not exist as a component part of the resultant motion of the membrane, it will not be in the least affected."

Without entering any further into this particular subject, I will simply call attention to the great importance of this experiment in clearing up the difficulties connected with the mechanism of the act of hearing. We can now understand clearly how through one and the same spot—the umbo of the drum-head, for instance, or the foot-plate of the stirrup, if all the other vibrating parts have been destroyed—composite tones of the most complex nature can be transmitted to the labyrinth, there to be analyzed, as it were, by the complete set of tuning-forks which it possesses—viz., the organs of Corti.

Prof. Adam Politzer, of Vienna, contributes an interesting paper to the *Archiv für Ohrenheilkunde** on "The Relations of the Stapedius Muscle to the Facial Nerve." Passing over the anatomical points, I will simply call attention to the results of certain experiments made by him for the purpose of ascertaining the function of the stapedius muscle. By exposing the intracranial portion of the facial nerve—which sends off branches to the stapedius—and placing a manometer tube (partially filled with a colored fluid) in the external auditory canal of a freshly killed dog, he found that, when an adequate irritation was applied to the facial nerve, a negative movement—by which I understand an upward movement—was observed in the column of fluid in the manometer. The same movement was observed in the case of the human ear, when, instead of irritating the nerve, the muscular fibres of the stapedius were drawn upon by the forceps. Politzer therefore concludes that *the stapedius muscle is in reality a laxator of the membrana tympani*. The same method of experimentation was applied to the labyrinth for the purpose of ascertaining whether the pressure upon its fluid contents was increased or diminished by the contraction of the stapedius. The sinking of the column of fluid in the manometer tube, when the muscle was pulled upon, showed that *it was also the function of the stapedius to diminish the pressure upon the labyrinthine fluid*.

During the past year the question of the function of the semicircular canals of the labyrinth has been revived with great vigor. The experiments made some fifty years ago by Flourens, and repeated afterwards by other physiologists, seemed to determine beyond a doubt that in these peculiar structures resided the power of controlling the equilibrium of the body. In 1870 Goltz repeated the experiments, and was led to the conclusion that the semicircular canals "were organs of sense for the maintenance of the equilibrium of the head, and soalso, indirectly, of the entire body." In 1872 Böttcher, of Dorpat, by operating in a somewhat different manner from that pursued by his predecessors, was able to divide the posterior vertical semicircular canal of the frog *without* producing in that animal any of the peculiar movements described by Flourens. This induced him to carry out a series of similar experiments upon pigeons, the results of which are published in the *Archiv für Ohrenheilkunde* for 1874. These are, in brief, the following:—

In those cases in which the operation was carried out without any special precautions, and in which, as a consequence, there was considerable hemorrhage from the vessels in the neighborhood of the semicircular canals, the results obtained were essentially the same as those described by Flourens, Goltz, and others, viz., twisting of the head to one side, rolling movements, travelling

* The American Journal of Science and Arts, vol. viii., Aug., 1874.

* Vol. ix., 3d fasciculus.

in a circle toward the affected side ("mouvements de manège"), unsteady and uncertain gait, pendulum-like motions of the head, etc. In one case the twisting of the head and the rolling movements did not appear until the fifth day after the second operation (division of the canal on the opposite side). At the post-mortem examination in this case the evidences were found of an acute inflammation of the dura mater in the vicinity of the region where the second operation had been performed, and extending thence to the portion which covers the cerebellar hemispheres.

In a second series of cases, although great care was used in performing the operation, the results varied very greatly. Thus in one case, after division of the inner vertical canal of one side, the bird showed a tendency to fall forwards, but this continued for only two days. After division of the horizontal canal of the opposite side, pendulum-like movements of the head began, and the bird showed a tendency to fall towards that side. The pendulum-like movements, however, soon ceased, and the bird slowly recovered the use of its legs. The power of flight was totally lost after the second operation.

In another case, after division of the semicircular canals, the tendency to move in a circle showed itself, but soon passed off. Although a semicircular canal on each side had been divided, no pendulum-like movements occurred. A short time after the operation, and notwithstanding the fact that the continuity of the semicircular canals was broken on both sides, no disturbance of the equilibrium could be noticed. Furthermore, the tendency to move in a circle scarcely showed itself at all when the bird walked, while during its flight it was very marked. The peculiar manner of holding the head sideways, and the attacks of bringing the head down in such a way that the top would touch the floor, did not appear as the immediate result of the operation, but for the first time as late as four weeks after the operation, that is, after the full disappearance of all the immediate effects of the operation. These peculiar symptoms were therefore due to some disturbances which must have developed at a later date, and were only indirectly connected with the division of the semicircular canals. The rolling movements appeared in connection with the twisting of the head whenever the bird was very greatly disturbed. There was no appreciable connection between the rolling movements and the tendency to move in a circle. The latter symptom was noticeable for a long time before the rolling movements appeared, and when these came the tendency to move in a circle disappeared altogether.

In still another case, after the division of both outer vertical semicircular canals, the twisting of the head and the rolling movements did not appear until after a lapse of about three weeks. There was total loss of the power of flight, and the left leg appeared to be permanently affected. At the autopsy, an extravasation of blood was found in the pia mater, on the left side, just over the origin of the acoustic nerve. The supposition is therefore justifiable that the symptoms which developed later—the twisting of the head and the rolling movements—were due to this extravasation.

Finally, in a fourth case, after the division of the lower arms of both vertical semicircular canals, the bird was still able to hold its head in a perfectly normal position. The ability to walk and the power of flight were very materially diminished; yet they improved very decidedly in the course of a short time. About ten days after the operation, well-marked pendulum-like movements in a vertical direction set in, and the power of flight appeared to be quite destroyed.

At last these symptoms, too, almost entirely disappeared. No lesions found in the brain or its membranes at the autopsy.

In a third series of cases the operation was performed more successfully, as regards the avoidance of injury to neighboring important parts; and in these cases, after the division of one or more semicircular canals on both sides, but very slight and transient motor disturbances followed; the birds in a very short time entirely recovered their powers of locomotion, of maintaining perfectly their equilibrium, and of picking up particles of food.

By these very important experiments Böttcher proves that the semicircular canals may be divided *without* causing any of the symptoms described by Flourens and Goltz as specially due to a lesion of this apparatus. If, as he says, the destruction of the semicircular canals were the cause of these characteristic motor disturbances, the latter should have persisted as a permanent thing; instead of this, however, they soon disappeared entirely, notwithstanding the fact that the apparatus of the semicircular canals had been practically destroyed. Another point to which he calls attention, and which certainly has a suspicious character about it, is this: *the motor disturbances, when only one side is operated upon, always appear in the extremities of the side upon which the operation has been performed.* Thus the movements in a circle are always executed toward the injured side. A slight paresis of the foot or wing of one side would be sufficient to cause these peculiar movements in a circle, which have hitherto been considered as something almost specific of a lesion of the semicircular canals.

In conclusion, Böttcher thus states his views regarding this question: "These disturbances of equilibrium manifest themselves either immediately after the operation—and are then due to an injury of the brain,—or after the lapse of a few days, in which case they are due to pathological processes, which have involved the central portions of the nervous system."

As regards an injury to the brain, Böttcher calls attention to the fact that the auditory nerve is not bound down at any point between its origin in the brain, on the one hand, and the fundus of the meatus auditorius internus, on the other; and that consequently any operative interference with the semicircular canals, which may result in pulling upon or tearing the ampullae or sacculi—that is, in pulling upon the vestibular fibres of the auditory nerve—must necessarily produce a certain amount of injury in that portion of the brain from which these fibres come. The variable results obtained from interference of this kind are due to the circumstance that at one time one set of fibres is pulled upon, while at another, another set. In this connection he quotes Brown-Séquard* as saying: "I have ascertained that the phenomena observed in these experiments do not depend on the section of these canals, as this operation may not cause these phenomena, but that they are the results of an irritation of the auditory nerve, from the drawing upon it by the membranous semicircular canals at the time we divide them."

In answer to the objection of some, that the motor disturbances here under consideration are of too long duration for so slight a lesion, and always take place on the side of the body corresponding to the lesion,—which does not agree with the generally accepted notion that an injury to one side of the brain should be followed by disturbances upon the opposite side

*Course of Lectures on the Physiology and Pathology of the Central Nervous System. Philadelphia, 1864, p. 195.

of the body—Böttcher again cites the following remarks of Brown-Séguard (loc. cit.): "It is a fact worthy of attention, that a puncture with a needle through the anterior pyramids, which contain very nearly all, if not all, the nerve fibres employed in voluntary movements, will hardly produce a momentary contraction in some muscles; while certain punctures through the olivary column of the medulla oblongata at once produce a spasm of many muscles, although this column does not contain more than very few (if any at all) voluntary motor fibres! And now, to add to the strangeness of the fact, in this last case, the muscles remain contracted sometimes for hours, sometimes for days and weeks."

"..... There is, therefore, in some parts of the nervous centres, a property of acting in a persistent manner to produce muscular spasms, during and after a mechanical excitation."

"..... The parts of the base of the encephalon, which are capable of producing persistent spasms, seem to be quite different from those employed in the transmission of sensitive impressions, or of the orders of the will to muscles, at least in the medulla oblongata and the pons varolii. They constitute a very large portion of these two organs, and perhaps the three-fourths of the first one; they are placed chiefly in the lateral and posterior columns of these organs; many of their fibres do not decussate, and produce, therefore, spasms on the corresponding side of the body."

This is important evidence in favor of Böttcher's view; showing, as it does, that a slight injury of the medulla oblongata—the very part of the brain from which the auditory nerve springs—may result in motor disturbances on the corresponding side of the body, and furthermore that these disturbances may last for quite a length of time.

Böttcher's paper covers the ground very thoroughly, and well deserves the attention it is sure to receive from all who are interested in the physiology of the organ of hearing. It is a model of careful, patient research, calmly carried out by a man who seems to have but one motive—the ascertainment of truth.

The department of pathology, too, has been enriched by several valuable contributions. Wilhelm Meyer's paper on "Adenoid Vegetations in the Naso-pharyngeal Space," begun in the last number of the *Archiv für Ohrenheilkunde* for 1873, was finished in the March number for 1874. The pathological condition here referred to is one which has a most important bearing upon the organ of hearing. Out of 175 cases Meyer found that 130, or 74 per cent., were hard of hearing. As the mucous membrane of this region passes by direct continuity into that of the Eustachian tube and middle ear, we can readily understand why in so large a proportion of the cases the organ of hearing should participate in the naso-pharyngeal inflammation. The pathological condition here referred to consists in the presence of numerous, variously shaped tumors in the naso-pharyngeal space. These vary in size from a mere follicular enlargement to a mass the size of a cherry-pit, or even a hazel-nut. Sometimes they are pedunculate, at other times they are grouped together in a row, like the teeth of a comb. These masses are very vascular, and consequently of a bright-red color; they have about the same consistency as the parenchyma of the liver, and present either a smooth surface or one that is slightly granular. They rarely occur singly; as a general thing, there are from four to eight of them present. The presence of these tumors implies a degree of inflammatory irritation in the mucous membrane of this region which can hardly exist without an inflamed condition

also of the Eustachian tubes at least. But these tumors may injure the organ of hearing in a simple mechanical manner; thus Meyer relates cases where one or two of these tumors, growing from favorable points, attained such a size as to entirely blockade the entrance or entrances to the Eustachian tubes. The microscopic examination of these tumors revealed them to be composed chiefly of what he terms "adenoid tissue," viz., a network of connective tissue supporting countless lymph-corpuscles, or lymphoid cells, as they are sometimes called. Here and there throughout the section the outlet ducts of acinous glands were also encountered.

The chief symptoms characterizing this affection are the peculiar expression of the face, and the defective pronunciation of certain words; both of these conditions being generally associated with more or less deafness. As regards the expression of the face, Meyer describes it in the following words: "In well-marked cases the mouth is constantly open, and the breathing takes place exclusively through it. There is also a lack of tone in the play of the features, and the expression is characterized by a certain shade of sadness. After the breathing has taken place for some length of time exclusively through the mouth, the nose assumes a peculiar sharpness of outline; it looks pinched, and the alae appear to be sunken. If it happens that the patient is at the same time suffering from a chronic nasal catarrh, this peculiar expression of the nose will, of course, not exist."

The pronunciation is defective in two ways: in the first place, the voice lacks the normal resonance, and in the next, the nasal tones—m, n, ng—are exchanged for others. So, for example, the patient does not say "nose," but "dase," or "lase." Again, for the word "Zimmermann," he will say "Zibberbad," and for "Gesang," "Gesargk," and so on. These, of course, illustrate the modifications of pronunciation in a well-marked case. Such patients, Meyer says, have also great difficulty in singing high tones. Among other symptoms, he mentions the partial or total loss of the sense of smell, habitual headaches, the sensation of a foreign body in the back part of the nose, and the frequent escape of blood from the naso-pharyngeal region into the mouth. This last symptom he noticed in a little over 15 per cent. of all the cases that came under his observation.

While in this form of disease a positive diagnosis can only be made by physical means—inspection of the naso-pharyngeal cavity by aid of the rhinoscope and reflected light, or an examination of these parts with the finger, introduced through the mouth—we can nevertheless expect confidently to find adenoid vegetations in the naso-pharynx whenever we encounter the peculiar expression of countenance and the defective pronunciation described above. Thus Meyer states that he examined 2,000 school-children of both sexes in the public schools of Copenhagen, for the purpose of ascertaining simply by looking at their countenances and hearing them speak, how many of them were suffering from this affection. He found 20 children (1 per cent.) in whom these characteristics were well marked, and in each instance he verified the diagnosis by a digital examination through the mouth. Meyer made a similar investigation in England, and found the proportion to be 13 out of 700, or nearly 2 per cent.

As regards the question of age, Meyer found that, out of 175 cases, 134, or 76 per cent., were between the ages of five and twenty; the youngest patient was three years old, the oldest fifty-nine. In a few instances he found that there was a family tendency to

this trouble; thus, in three instances three sisters were affected with the disease, and in seven, two sisters.

As regards the etiology of this disease, Meyer simply states that the same causes which co-operate to produce a chronic catarrh of the naso-pharyngeal mucous membrane, are active in the production of adenoid vegetations.

So far as his observations go, Meyer believes that these adenoid vegetations, which usually commence to grow during childhood, but remain stationary during youth, will, if left to themselves, shrink away and disappear during maturity. Hence, so far as they themselves are concerned, these vegetations might be allowed to remain without any interference on the part of the surgeon; but when we take into account their important bearings upon the organ of hearing—not to speak of the unnatural and disagreeable tone of voice which they produce—it becomes necessary to get rid of those already formed, and to check the further production of new ones. The prognosis, as regards the results of treatment, seems to be quite good. Meyer states that among a number of cases which remained under observation for a period of from two to five years, and in which the vegetations had been thoroughly removed, not a single relapse occurred. The prognosis as regards the hearing is also quite good. Out of 112 cases which had undergone proper treatment, the hearing was restored to the normal standard in 48 instances; in 29 it was improved; in 3 it remained unchanged; in 3 it was rendered worse; and in 29 cases no note was made regarding the effects of the treatment upon the hearing. This result appears in a still more favorable light when we examine the cases with regard to the length of time the deafness has existed. Meyer has classified the results in the following tables:

TABLE I.

Duration of Deafness.	No. of Cases Treated.	Cured.	Per cent.
Less than 3 months.....	10	5	50
From 3 to 12 months.....	12	5	41.7
From 1 to 2 years.....	17	9	52.9
From 2 to 5 years.....	23	11	47.8
From 5 to 10 years.....	21	7	33.3
More than 10 years.....	21	10	47.6
Indefinite.....	8	1	12.5
Total.....	112	48	42.9

TABLE II.

The Hearing	Simple Catarrh. No. of Cases.	Purulent Inflammation. No. of Cases.	Total.
Was rendered normal in.....	34	14	48
Was improved in.....	18	11	29
Remained unchanged in.....	3	—	3
Became worse in.....	—	3	3
Was not tested in.....	23	6	29
Total.....	78	34	112

As regards the question of treatment, the essential thing, according to Meyer, is to remove the vegetations, whether by mechanical or by chemical means. In children, and where the vegetations are not large or too firm in texture, they can be destroyed by pressure made with the finger. If this cannot be done, we must resort to the use of some caustic, preferably the nitrate of silver, either in the pure form or mitigated by the addition of nitrate of potassa. The instruments to be used for this purpose are silver rods, armed with a flattened end-piece, and differently shaped, so as to enable the surgeon to cauterize readily growths springing from any part of the naso-pharyngeal space.

Where the growths are large, and especially where they are firm in texture, it becomes necessary to use other surgical contrivances, such as the galvano-cautery, a double-bladed instrument like that used for crushing urinary calculi, a ring-shaped knife, etc. Whichever of these plans of removing the growths may be adopted, Meyer lays great stress on the frequent use of Weber's naso-pharyngeal douche.

Dr. D. B. St. John Roosa contributes a valuable paper on the "Etiology of Diseases of the Internal Ear." Out of 1,700 cases of ear affections, he found sixty-five, or nearly four per cent., that were suffering from disease of the internal ear. These cases Dr. Roosa divides into those of traumatic origin, and those which have arisen idiopathically. Among the cases of traumatic origin are classed those in which the deafness was caused either by a single and pretty sharp blow (falls and direct blows), or by a long-continued series of less violent shocks or blows, such, for instance, as the cannoner, the boiler-maker, or the telegraph operator is subjected to. In discussing the subject, Dr. R. alludes to the interesting question "of why it is that some persons, afflicted with impairment of the hearing, hear better in the midst of noise," and expresses the view that all the explanations hitherto given of this phenomenon appear totally inadequate to explain it.*

Of the idiopathic cases eleven are attributed by Dr. Roosa to "hemorrhage into the internal ear, producing atrophy of nerve tissue;" two to "inflammation of the parotid gland, from which a catarrhal or periosteal inflammation extended to the labyrinth;" eight to "cerebro-spinal-meningitis, producing inflammation of the auditory nerve, or the labyrinth, or both;" two to "scarlatina, causing an extension of pharyngeal or meningeal inflammation to the labyrinth;" one to "measles, producing the same effect;" seven to "basilar meningitis, extending to auditory nerve, or labyrinth, or both;" eight to "primary inflammation of labyrinth or circumscribed basilar meningitis (about the root of the auditory nerve);" four to "internal administration of quinia, causing congestion and inflammation of base of brain and labyrinth (?)" one, to "arrested development;" and fourteen to "unknown causes." In enumerating these different pathological conditions, Dr. Roosa undoubtedly means them to be understood as *probable* conditions; for our knowledge of the pathological anatomy of these cases is lamentably scanty, and unfortunately, is likely, from the nature of the case, to remain so for many years to come.†

* I cannot recall at the present time from whom, or from what source, I obtained the following explanation of this strange phenomenon, but it has always seemed a reasonable one to my mind, and I shall therefore take the liberty of mentioning it here in a very brief manner:—

The pathological condition in the cases here under consideration is assumed to be one of rigidity, either of the annular membrane or ligament which holds the foot-plate of the stirrup in the fenestra ovalis, or of the secondary tympanic membrane, covering the fenestra rotunda. Ordinary waves of sound, such, for instance, as are produced in ordinary conversation, are not of sufficient strength to overcome the rigidity of the annular ligament, or of the secondary tympanic membrane; consequently the patient fails to hear the conversation. In the midst of loud noise, however, waves of sound are produced of sufficient strength to set the stirrup in motion, in spite of the existing pathological obstacles. Once in vibration, this little ossicle, which might very properly be called the key to the auditory chamber, can perform with a certain degree of freedom the subordinate vibrations called into existence by the conversation which is being carried on near by, vibrations which are necessary to the act of hearing it. The louder tones open the door for the entrance of the feebler ones.

† I can think of only one way in which we are likely in time to obtain a more accurate knowledge of the pathology of these cases of so-called nervous deafness. It is this:—The different deaf and dumb institutions should be furnished with suitable blank forms of questions, by means of which the aural history of each pupil could readily be obtained. These blanks, when filled out, should be placed in safe keeping, and, whenever a death occurs in the institution, the proper authorities should, if the parents or friends do not object, invite some competent aurist or pathologist to conduct the post-mortem examination. A care-

Very little is heard nowadays about the operation of dividing the tendon of the tensor tympani muscle. The reports published in Germany were so favorable, that American aurists at once began to test for themselves the value of this operation, especially as a means of relief from tinnitus. Dr. Oren D. Pomeroy, of this city, publishes a report* of eight cases, in which he performed the operation. In all of them the symptom of tinnitus was prominent. In one case, the patient experienced complete relief from this annoying symptom, but in the remainder, little or no change was experienced. On the other hand, in one case the tinnitus was aggravated by the operation; and in another, in which the operation was commenced but not completed, a severe purulent inflammation of the middle ear resulted. While, therefore, the operation may in exceptional instances afford relief from tinnitus, it should hardly be advised except in urgent cases, where the patient is quite willing to run the risk of acute inflammation of the ear, for the sake of possible relief from a very annoying symptom.

In the department of aural therapeutics, I have no important advance to chronicle.

I should, perhaps, allude before closing, to the fact, that during the year two new text-books on diseases of the ear have appeared in the English language, one written by Dr. Roosa, of this city, and the other by Dr. Hinton, of London. Dr. Clarence J. Blake, of Boston, has also published an American edition of Rüdinger's photographic plates of the osseous structures of the ear, and has improved upon the original by the introduction of a plate taken from one of his own preparations. The appearance of these three important works, while, perhaps, they do not contribute much that is new to our knowledge of otology, indicates in a measure the increasing interest taken in matters pertaining to the ear.

Progress of Medical Science.

DIPHThERITIC PARALYSIS AND SUBCUTANEOUS INJECTIONS OF STRYCHNIA.—Among a number of cases reported by Acker of paralysis after diphtheria of the pharynx, there was one in which complete sensory and motor paralysis of the superior laryngeal nerve occurred. He found the explanation of this difficulty in the exposed course of this nerve along the middle constrictor of the pharynx, where the local injury was communicated directly from the seat of the disease to the nerve twigs supplying it, just as in paralysis of the palatal and pharyngeal muscles. In the same case there was a marked want of co-ordination, especially in walking, which the author called diphtheritic ataxia. The paralytic symptoms preponderated markedly on the right side. There was also obstinate constipation, which was referred to an insufficiency of peristaltic movements owing to paresis of the muscular elements in the intestine. The treatment was by galvanization of the spinal cord, and large subcutaneous injections of strychnia, to the latter of which the author attributes the rapid cure. A two per cent. solu-

tion should be made, not only of those parts constituting the ear proper, but also of the auditory nerve of the brain, especially the medulla oblongata, together with its membranes. A full record of the results of this examination should then be filed with the history of the case, and should remain in the possession of the institution. If the principals of our deaf and dumb institutions would interest themselves in this matter, it seems to me that we might reasonably look for important results at a not very distant future.

* Transactions of the American Otological Society, for 1874.

tion of nitrate of strychnia was used, and $\frac{1}{100}$ of a grain was injected daily, generally into the arm, as a general and not a local effect was desired, and this was the most convenient situation. The patient received by subcutaneous injection within the period of a month—a sum total of over seven grains of the nitrate. There was no local reaction or evidence of inflammation.—*Erlanger Med. Klinik.—Memorbilien*, April 8, 1875.

REASONS FOR AND AGAINST TRANSFUSION IN ACUTE AND CHRONIC DISEASE.—Billroth has arrived at the following conclusions regarding transfusion. In acute anæmia, injection of human blood may be justified in a case of the most urgent need, although hitherto it has seldom been used under such conditions; there are no other satisfactory indications for it, either theoretical or empirical. He regards it as still undecided whether human blood is to be used to the exclusion of the blood of other animals. When it is designed to substitute healthy for diseased blood, as in cases of septicæmia, there is no reason, on any theory, to look for a favorable effect from the introduction of new blood, which at the best is comparatively small in amount. Even supposing it possible to renew all the blood in the system, the success of the operation would hinge upon the assumption that the putrid poison was present in the blood only, which is neither proved nor yet probable. He is also decidedly opposed to the view that there are either theoretical or practical reasons to expect anything at all from transfusion in chronic diseases.

In this connection some recent experiments of Landois are of interest. It seems to be established that the blood-corpuscles of animals, when introduced into the blood of another animal, are dissolved, with the result of forming coagula in the interior of the circulatory system, and to this phenomenon Landois is inclined to attribute all the symptoms noticed subsequent to those immediately following the transfusion, and attributable to the plugging up of the capillaries and small vessels. Sometimes, too, this plugging of the capillaries is due to these blood-corpuscles collecting together in masses before dissolving, the evidences of which consist in stases, extravasations, and sero-sanguineous effusions found on section of animals treated by transfusion. The corresponding symptoms during life are dyspnoea, increased peristalsis, vomiting, the occurrence of hæmoglobin and albumen in the urine, and the decrease of urea; coldness of the skin and the formation of an exanthem resembling urticaria; rigidity and contractions of the muscles; irritation succeeded by depression of the nervous system and capillary hemorrhages from wombs. He concludes, then, that the transfusion of animal blood in chronic disease cannot exert the favorable effects reported, because of the renewed functional activity in the foreign blood-corpuscles, for these are dissolved; such good effects, if they occur, are rather due to stimulation of the organism as by an alterative.—*Wiener Med. Woch.*, No. 4, 1875.—*Berl. Klin. Woch.*, April 12, 1875.

SYMBLEPHARON TREATED BY THE TRANSPLANTATION OF THE CONJUNCTIVA FROM A RABBIT.—This operation has been performed in two cases by Prof. Otto Becker, of Heidelberg. The first was in a young man of seventeen, in whom a second operation was required for the relief of a small symblepharon near the canthus, which remained after the larger primary symblepharon had been treated by a plastic operation. The original injury had been a burn with melted zinc. Becker dissected off the symblepharon from within outwards and stitched it to the inner surface of the

lid. The loss of substance was then made good by a piece about 8 mm. square from the conjunctiva bulbi of a white rabbit. This was stitched in at its four corners with very fine untwisted silk, and a simple compress and bandage applied. There was no change in the appearance of the graft till the third day, when vessels could be distinctly seen in it. The result was highly satisfactory, the portion of rabbit's conjunctiva becoming thoroughly identified with its new surroundings. The second case was in a boy of four years with symblepharon following a burn with lime, for whom there had been two unsuccessful operations by other surgeons. In this case the palpebra tertia of the rabbit was used, after the cartilage had been dissected out. It would not lie perfectly smooth, and the child was restless, so that on the day following the operation the engrafted piece was detached and rolled up, and about two-thirds of it sloughed away. Still the operation resulted in a substantial improvement in the mobility of the globe. Becker in this connection suggests the employment of the human conjunctiva, which is to be obtained from atrophied eyes instead of from the rabbit; and on the other hand suggests that a too small conjunctival sac in an atrophied eye might be advantageously treated by the new method.—*Rundschau*, April 12, 1875.

FRACTURE OF THE CLAVICLE BY MUSCULAR ACTION.—In a former paper, M. Deleus has shown that fractures of the internal end of the clavicle are produced by muscular action. In more than two-thirds of the cases in the present article, in which he treats of fracture of the body of the bone, he shows that, although this arises from muscular contraction less frequently, yet this occurrence is not so very rare, as he has met with three cases in his own practice, and has found records of sixteen others. These have been usually met with in men from twenty-five to sixty years of age, and on the right side. The influence of debilitating diatheses—especially syphilis, and local changes in the bone, from osteitis, gummy tumors, etc.—is the predisposing cause of these fractures.—*Archives Générales*, March, 1875.

PHARYNGOTOMY FOR THE REMOVAL OF A FOREIGN BODY FROM THE PHARYNX.—At a meeting of the Surgical Society of Ireland, on March 19th, Mr. Wheeler reported that he had performed pharyngotomy, and had successfully removed a foreign body from the pharynx, this operation being the first that had ever been performed in that country. It was in the case of a robust man, 45 years of age, who had accidentally swallowed a needle. The laryngoscope showed the needle, somewhat obliquely situated, with its eye buried in the left palato-pharyngeus muscle, its point in the left arytenoid cartilage. Attempts were made to extract it with the forceps, but it appeared to slip through the blades. Finally it became so firmly lodged that all attempts to depress or dislodge one end of the needle were ineffectual. As the patient became thin and pale, and was unable to swallow solid food, and occasionally suffered considerable pain, pharyngotomy was determined on.

An incision was made on the left side of the neck, from the body of the hyoid bone to the superior margin of the cricoid cartilage, through the integument and fascia. A small vessel, which was thought to be the sterno-mastoid branch of the superior thyroid artery, had to be tied. The layers of the fascia were taken up and cautiously divided on a director, until the common, external and internal carotid arteries, the superior thyroid artery, and superior laryngeal nerve, with some filaments of the ninth nerve, were exposed

to view. The attachment of the omo-hyoid muscle was then separated. A staff passed into the mouth was made to push out the left side of the pharynx and an incision sufficient to admit the top of the index finger made down on it. The staff being removed, the opening was enlarged upwards and downwards and a finger passed behind the ala of the thyroid cartilage, but the needle could not be felt. Fortunately it was threaded, and Mr. Wheeler passing the threads out through the incision, and following them down to the tissue, was able, by scraping with his finger, to make out the head. It was then drawn out through the wound. No sutures were put in the gullet; the edges of the wound were approximated with carbolized sutures, and lint soaked in carbolic oil was laid over the wound; nutritive enemata were given, and a sponge soaked in iced milk was occasionally squeezed into the mouth, or the milk was given in teaspoonfuls, and though some came out through the wound the greater part followed the natural course. After eleven days fluid ceased to come through the wound, and the patient was discharged cured, after the lapse of another fortnight.

Mr. W. suggests in an operation of this kind the desirability of immediately arresting the hemorrhage from the small vessels necessarily divided; having the vessels well retracted; having a staff put into the pharynx from the mouth; of not passing a knife into the pharynx to enlarge the opening up and down as recommended by Mr. Cook; he says, do not mistake the thyroid gland for the gullet; operate on the left side as being more convenient than on the right, unless contra-indicated by the position and size of the gland.—*Irish Hosp. Gaz.*, April 15, 1875.

AN ICELANDIC SKIN DISEASE.—Dr. Finsen, in his recent work on the diseases of Iceland, describes, under the name of "Fox-worm" (*Rævorme*), a skin disease that appears to be quite peculiar to that country. It attacks the hands only; red, slightly elevated patches, about the size of a three-cent piece, are formed on the dorsal surface, and on these patches small vesicles are developed. After the eruption—which, as a rule, commences near the wrist—has lasted some time, it dries up and disappears, apparently by desquamation, to be followed by a similar outbreak further down on the back of the hand, and a similar desquamation, and thus it gradually approaches the extremities of the fingers. On the palmar surface, the disease appears as cracks and furrows. When the eruption reaches the extremities of the fingers the matrix of the nail appears to be attacked; for the nail, without apparent inflammation or ulceration, is completely loosened, becomes brittle, and splits up into laminae. The disease may continue for a long time in this stage, but after a longer or shorter time the nail falls off, and there is formed in its place, commencing at the matrix, a hypertrophic, deformed, rough nail, which is markedly lamellar in its structure, and generally projects beyond the end of the finger. In this case its free end is thickest. Sometimes it does not reach to the end of the finger, in which case it is thickest at its middle. Such a nail is called in Iceland a "kartnögl." When, after a long continuation of this disease, the nail is formed, the process ceases, though the results remain, and the *kartnögl*, and sometimes a shining condition of the skin of the hands,—which have lost their natural softness—last the remainder of the patient's life. The disease is regarded as incurable. The author considers it of parasitic origin, but does not state whether it is contagious. He has observed thirty-one cases.—*Hospitals-tidende*, Dec., 1874.

REFORM IN MEDICAL EDUCATION.

THE lively competition among our medical colleges has begotten a disposition to rest their respective claims for superiority upon the size of their classes and the number of their graduates. This has certainly a very dangerous bearing upon the progress of medical education. So long as it is conceded that the number of matriculants settles the respectability of any given college, there is always an ambition among rival institutions to get all the students they can. The temptation to resort to questionable means to gain this patronage is not always resistible, even by professors whose consciences are tender upon every other subject. The question seems not to be, how can we narrow the attendance upon our medical schools to a first-class standard of fitness, but how far can we go in order to insure the greatest number of names in our catalogues? When quantity is so much the primary consideration with our medical institutions, it is easy to see how strongly the current sets against mere quality—in other words, wherein lies the objection to the enforcement of some regulation requiring a preliminary examination on the part of those who seek admission into the schools.

It is useless to strive to alter the sentiment upon the question, and although every medical teacher must acknowledge that his position as a tacit supporter of the present system of medical education is an anomalous one, his college interests are apparently too strong to allow him to be just to himself or reasonable to his patrons.

The remedy in regard to preliminary examinations, of which we have already spoken in a previous issue, is simple enough; but its application is so complicated by the determined opposition of a few interested parties, that any hope of reform seems a long way off. The present management of our colleges is such that there is really no guarantee that any particular graduate has had even an ordinary preliminary education.

There is no examination to determine this point before the student enters, and there is certainly none when he comes up for graduation. The anxiety to have a large graduating class would make such an examination, even if it were required, the merest matter of form.

The fact is, each medical institution has an individual monopoly of every student, from the time he enters until he receives his diploma. If the standard of a particular school is low, it matters not, so long as that school has the power to say that the said standard is high enough to answer its individual requirements for graduation. With so many different schools, and with so many corresponding differences in the requirements for graduation, it is reasonable to suppose that the qualifications which conventionally belong to the title of Doctor of Medicine are very variable and of very uncertain value. It is this monopoly of medical education on the part of the colleges which is one of the main obstacles to our progress in educational matters. If there could be some power which could prevent the graduation of any person not properly qualified, a very important step would be taken. To make this possible, the first thing to do is to deprive any medical college of the power of examining its own students. Let the medical professors be teachers merely, but let the board of examiners be an independent body, who are above even the suspicion of partiality. This is done in other countries, and we see no reason why it could not be done in ours. Each State could, by the recommendation of its Medical Society, appoint an examining board, whose duty it should be to examine all applicants for a degree of Doctor of Medicine. This plan would certainly stimulate the colleges to do their best to have their students pass this board, and a true and legitimate spirit of rivalry would be at once engendered. Each college would then strive for the distinction of the best school, rather than the largest school. There would then be no difficulty in having medical colleges insist upon preliminary examination, for their very reputation as institutions of learning would demand it.

This system of independent examination would stimulate the best kind of teaching in every way. No student would be bound to any given institution, but could be free to avail himself of the special advantages of each, it being sufficient for all practical purposes that he divides his complete course of study among all. Those colleges which had the greatest number of good teachers would then have the largest aggregate attendance, while the student could have the opportunity to choose the best teachers in all the branches. In our large cities, where there is more than one medical college, this plan could easily be adopted, and, in fact, because these advantages could be obtained only in large cities, the greater number of students would congregate thither, thus causing many of the mediocre schools to die for want of patronage.

The establishment of an independent examining board is, in our opinion, the only way we can enforce a proper standard of medical qualification. This would make the profession entirely independent of school influence. The question would then be not what the colleges taught, how long were their sessions, what were their clinical advantages, what was the reputation of their professors; but what their respective students knew when they came before a thoroughly impartial board. We cannot see how the colleges could suffer by any such arrangement, for the better the college the greater its chance of a large class. We have a board in this State competent to examine all applicants who have conformed to the requirements of the law as to time of study, etc. Although this board has been appointed for the purpose of examining only occasional applicants for a degree, its organization could be so perfected, and the details so arranged, that all the graduating classes of the State could come before it. We believe that one of the starting-points of reform in medical education would be the establishment of such a board in every State.

Reports of Societies.

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting, May 13, 1875.

DR. E. R. PEASLEE, PRESIDENT, in the Chair.

ON THE RELATION OF ALIMENTATION TO GASTRO-INTESTINAL DISORDERS OF INFANTS AND YOUNG CHILDREN.

BEFORE the reading of the paper which Dr. B. F. Dawson presented upon the above subject, he exhibited the intestines taken from a child seven months old. Up to the age of three months the child was apparently quite well, when it was taken with severe vomiting, which was protracted and followed by diarrhoea that kept up until general wasting was produced. Post-mortem was made four hours after death, and at various points in the intestinal tract the walls of the intestines were so softened by degenerative processes, that it was with the greatest difficulty that they could be removed and laid open without tearing. The rectum was entirely impervious, and during the last 72 hours of the child's life nothing whatever had passed. In those portions which were so agglutinated the walls of the gut were about the consistency of soft gum, and it was thought probable that nothing was left of the muscular coat, and there was remaining only the softened mucous membrane and peritoneum. There were no evident lesions of Peyer's patches. The specimen illustrated the softening which may take place in the walls of the intestine as the result of protracted gastro-intestinal disease.

The object of the paper read by Dr. Dawson was to furnish, if possible, some information which may be useful in our efforts for saving infant life. In order that the hearer might have a distinct appreciation of the importance of the question, the doctor referred to the fearful mortality which is seen in infancy,

and stated that *one-fourth* of the children die before they reach the age of five years. From the study of statistics made by Ballard, of England, and those reported to the Academy of Medicine in Paris, and from his own experience and study of statistics in this country, he had arrived at the conclusion that deprivation of the natural food, and improper management of infants who must be brought up upon artificial food—in short, faulty alimentation—is the chief cause of gastro-intestinal troubles, which carry off a great majority of this one-fourth of all the children who die. So convinced was he that the root of the evil was to be found here, that he would much rather undertake the treatment of infants and children without a single article from the materia medica, but trust to careful attention to alimentation, than to trust in medicines in case only one resource could be placed at his command. The composition of the mother's milk and the anatomy and physiology of the digestive apparatus of the infant accord, the one being adapted to meet the requirements of the other. During the first month of infant life there is no secretion from those glands whose products digest the starchy elements of food; and the size of the liver and shape and size of the intestinal tube all go to show that whatever food is taken will be retained only for a short time, therefore should only be of that quality which is most quickly and easily digested. Still further, it goes to prove that fluid and not solid, that animal and not vegetable food is the proper alimentation for a child. If these requirements are not fulfilled, it necessarily follows that whatever is introduced into the stomach and intestinal canal is exceedingly liable to give rise to vomiting, gastro-intestinal catarrh, and gastro-intestinal disorders of various kinds, which ultimately lead to fatal results.

As to the quantity of food demanded for the infant, it is perhaps difficult to decide. The child, however, should not be induced to take any more than is sufficient to satisfy the appetite, and when this is satisfied it should at once be removed from the breast. This simple truth is one which is constantly lost sight of by mothers in general, and the common supposition is that every cry means hunger, and that the child requires an additional amount of food. Too large quantities, and too often repeated, should, however, be carefully avoided. If the stomach is kept over-distended, it is almost as bad as to feed the infant upon indigestible food. There is one positive guide with reference to the quantity of milk to be taken, and that is, when the child eructates the milk soon after nursing it is evidence that it has been over-fed, although by very many mothers it is considered as an indication of health. Such vomiting, it is true, may be due to fault in the mother's milk; but this can be so easily detected, and should be so readily recognized, and, in fact, is so rare, that it may be safely said that such eructations are due to over-feeding. Chronic vomiting and gastro-intestinal disorders can quite commonly be traced to this cause. Frequency of nursing also has very much to do with the production of gastro-intestinal trouble. Upon this question there is a great diversity of opinion. It is usually considered sufficient to give the breast to the child every two or three hours during the day, and once or twice during the night. Digestion does not go on so rapidly when the child is asleep as when awake, hence it should not receive food nearly so often as when awake. If food is taken as frequently during the hours of sleep as during the waking hours, it comes in contact with indigested food, or food but slightly digested, and is extremely liable to give rise to colicky pains, diarrhoea, etc. The majority of cases

of gastro-intestinal matters which occur in infants, who begin life as healthy children, with healthy mothers, are due to over-feeding and too frequent feeding. But suppose we are called to attend a case where vomiting and intestinal troubles have been going on for some time, and the child is emaciating, etc., what are we to do? Shall we remove the child from the breast for a time—shall we give the stomach rest? The doctor's answer was, unhesitatingly, yes. According to the urgency of the case, stop all medicines, stop all alimentation, except, perhaps, a teaspoonful of cold water every fifteen or twenty minutes, and give the stomach absolute rest for twenty-four hours, and when nursing is resumed let the child nurse only a few mouthfuls, at moderate intervals, and this should be kept up for eight or ten days, when it will quite frequently be found that the normal quantity of food can be taken without trouble.

Constipation as well as diarrhoea is very often due to over-feeding and too frequent nursing. The stomach is over-taxed, and the food, instead of being coagulated in a fine coagula, comes in contact with old coagula, and the coagula then formed are large and hard, and, if not thrown up by the stomach, pass into the intestinal canal but little or not at all changed, and there, as hard, dry masses, give rise to constipation. It is an accumulation of such curds that sometimes gives rise to intestinal catarrh, which may finally terminate in severer forms of intestinal disease, and is probably one of the frequent causes of cholera infantum. Abnormal acidity of the stomach may sometimes be the cause of the formation of such abundance of coagula, but that is the exception and not the rule.

ARTIFICIAL DIET.

If this be judiciously selected, there is no reason why a child should not thrive as well upon artificial food as when its support is derived from the mother's breast. No food is capable of properly nourishing an infant unless it possesses heat and fat-producing properties. Any nourishment which does not come up to the requirements of a liquid food having the proper quality will produce intestinal troubles. What nourishment are we to give? Is there any one kind of nourishment which uniformly and perfectly supplies the place of breast-milk? The article which most perfectly answers all the requirements, and can be trusted to furnish all the elements of nutrition in the most digestible form, is milk from some animal. The milk of various animals varies to a certain extent in the properties of its different constituents; but the milk of the cow is the one which should ordinarily be used, and when properly prepared may answer all purposes. In its natural state it is not a fit article of food, and some article must be added which will effect a proper dilution. Water is the article commonly added; but by far the greater number of cases suffer in consequence of its addition. The addition of water alone does not improve the digestibility of the casein, for it does not dilute it; and when milk is introduced into the stomach, diluted with water, the water is soon taken up and the casein is left as undiluted and unchanged as before the food was given. Nor does the addition of sugar make the coagula any more easy of digestion; nor does skimming the milk act beneficially, but, on the contrary, deprives it of one of its most important constituents. Inasmuch as the mother's milk contains proportionately more fat than other milk, may it not be true that the finer coagula which is formed, when the mother's milk is introduced into the stomach, is due to the presence of this fat? and would it not be better to use the milk as an article of

food, from which casein has been removed, rather than use the milk which has been deprived of its cream? It had been his experience that this was the more proper course to pursue. The admixture of farinaceous articles with the milk also leads to disastrous consequences. There is one article, however, which contains such small quantities of starch that it can be used with very great success for effecting a proper dilution of cows' milk, and that is barley-water. Good cows' milk diluted from one-third to one-half with barley-water forms one of the best articles of food that can be used for infants when it is necessary to bring them up artificially. If barley cannot be obtained, oatmeal may be substituted, and answers nearly as good purpose. This article produces a real dilution of casein, and renders the coagula much finer and more nearly like the coagula which is found in milk from the mother's breast.

FOOD FOR INFANTS DURING DENTITION.

There is a prevailing opinion that the child requires a much more substantial food when the teeth begin to appear, and also that the existence of a diarrhoea of greater or less severity, during this period, is a thing to be expected; consequently, when the child suffers from any gastro-intestinal trouble while the teeth are cutting, it is altogether dependent upon that process. The doctor expressed his conviction that faulty alimentation is the chief cause in the production of the gastro-intestinal troubles met with during this period, and that if the child requires a more substantial diet, it should be only such as contains milk as its chief base.

The paper was listened to with great attention, and the author concluded by saying that not all gastro-intestinal diseases could be avoided with the most assiduous care and attention to the diet of children; but that, as a result of his experience, he believed a great majority of these cases are due to improper alimentation, both as regards the quantity and quality of the food administered.

DR. JOEL FOSTER remarked that he regarded the paper of the evening as plain and practical. He had been particularly interested with regard to the question of over-feeding infants, and believed that almost as much mischief can be done in this way as by under-feeding. He was also convinced of the very great necessity of the mother nursing the child during the earlier period of its life, for she alone can furnish the real natural food for it.

With regard to artificial food, it was a subject in which he was particularly interested as being connected with the New York Infant Asylum. In that institution it is impossible in many cases to get natural food, and they are obliged to use some substitute, and the substitute which can best be made is cow's milk. The method of preparing it which he had followed was to allow the milk to stand until the cream begins to rise, and then take the upper portion and dilute it with barley-water. He was then particular that the food should be given at regular intervals, and it should always be so given at a temperature near that of the human body, for if given below that degree it is very likely to produce gastro-intestinal troubles, which destroy so many children. It had been found that milk taken directly from the cow and given to the children did not do nearly as well as when permitted to stand for about two hours, when a partial separation of the cream has taken place, and then taking the upper portion of the milk. In this way more fat and less casein is obtained.

DR. PORTER held that perhaps hot weather and

other influences had very much to do with producing this class of diseases as well as improper alimentation.

DR. MESSINGER urged the propriety of thoroughly cooking whatever article was used for diluting the milk, and he always insisted that the barley-water should be boiled for three or four hours.

DR. GARRISH objected to keeping the milk upon which the child is to be fed in the ordinary ice-box which contains meats, vegetables, etc. A convenient refrigerator can be made of a common stone crock, by placing a piece of ice wrapped in flannel in the bottom of it, and there the milk can be kept with the greatest ease.

DR. McILVAINE regarded dilution of cow's milk as improper. He believed that the parotid glands secrete from the earliest period of life, and looked with a great degree of caution upon the statements made concerning experiments said to prove to the contrary.

DR. ROBERTS referred to one point which had not been spoken of with regard to cow's milk, and that was that it is generally acid, while mother's milk will usually be found to be alkaline. He did not think that cow's milk is the best substitute that can be used for breast milk.

DR. HANKS spoke with reference to the fact that among that class of people where gastro-intestinal diseases prevail most extensively, the children are poorly cared for as well as ill-fed, and that it is a very common thing to find them overburdened with clothing during the hot weather.

DR. LEWIS SMITH remarked, with reference to the use of farinaceous food, that up to the third month the salivary glands and pancreas are present only in a rudimentary state, consequently that fluid which is afforded by the animal economy for the digestion of starchy material is absent, but it is also probably true that the starch is not so irritating as is casein undigested. He has been accustomed to use the upper portion of the milk after it has stood for a short time, and prefers to use some article for dilution in which the starch has been changed into dextrine or glucose, and recommends Liebig's food. He does not think that sugar should be added at all during warm weather when diarrhoea is present. If there is constipation he gives sugar, and sugar of milk is the best form in which it can be employed. He was of the decided opinion that many deaths occur among children from the fact that the mother regards eight, ten, or twelve stools every day as necessary while the child is teething. This widespread error should, if possible, be corrected.

DR. ROBINSON suggested that the weight of the child might determine whether it was receiving sufficient food or not. Decrease in weight might be due to other causes, but a careful observation would enable us to strike out these liabilities to error, and enable us to determine whether the decrease was due to insufficient supply of food or not.

NEW JERSEY STATE MEDICAL SOCIETY.

One Hundred and Ninth Annual Meeting at Atlantic City, N. J., May 25th and 26th, 1875.

THE 109th Annual Meeting of the New Jersey State Medical Society took place at Atlantic City, on Tuesday and Wednesday, May 25th and 26th. It brought together, as usual, a large assemblage of leading New Jersey physicians, and this year was honored more than usual by the presence of several from other States.

The railroads afforded unusual facilities, the Camden and Atlantic Railroad conveying all in attendance free of charge, and even the City by the Sea gave a hearty welcome. The Camden County Society made most perfect arrangements, and added a most enjoyable collation to the other entertainments.

The President this year was Dr. G. H. Larison, of Lambertville, who is both a laborious physician and a Baptist preacher. His address reviewed the history of medicine, was elaborate and comprehensive, and fulfilled the expectations of those best acquainted with the author.

We noticed upon the platform well-known assistant officers, Drs. Wm. O. Gorman, J. V. Schenck, II. R. Baldwin, Wm. Elmer, Wm. Pierson, W. Phillips, S. Wickes, and, by invitation, Professors Gross, Agnew, and Levis, of Philadelphia, and Dr. Buck, of New York; Profs. Gurney, H. C. Wood, Goodell, and others, of Philadelphia; Dr. Adams and Dr. D. B. Hunt, of New York. Besides delegates from the State Societies of New York and Pennsylvania, there was also able representatives from Massachusetts and Rhode Island, whose presence and cheering words added zest to the occasion. At the banquet Profs. Agnew and Gross, and Dr. R. J. Levis, spoke for the profession in Philadelphia, and Dr. Newman for New York, and all with great acceptance. Response was made by members of the profession in New Jersey. Mr. John Lucas, on behalf of the Camden and Atlantic Railroad Company, also made an appropriate and acceptable speech.

The business meeting reports were heard and acted upon with executive promptness, in order that due time might be secured for strictly medical matters. As the time allotted to the meeting was taken up with the regular order for each period, corresponding members were invited to occupy an hour before the full session of the morning.

Many listened with interest to two excellent illustrative cases of pelvic abscess, by Dr. Buck, of New York, which were reported and commented upon with his usual ability. The report of the Standing Committee was read by its chairman.

DR. WICKES, as usual, gave a terse and excellent resumé of the various reports from the county societies, with reference to such cases as will be reported in full in the Transactions. Throat disease and scarlet fever were noted as having occurred in very many localities the past year, while there was a decrease in all alimentary disease. The severe winter seems to have added to bronchial and pneumonic mortality, but especially among the aged. Variola had prevailed in two localities. A case in which the sudden death of three children seemed to have occurred from the use of the milk of a cow, which had broken pasture and drank of very foul water, had in it some points requiring investigation. A peculiar form of rash, a kind of mongrel roseola and rubeola, accompanied with typhoid symptoms, which readily yielded, had prevailed in one or two localities. It has been a year of unusual fecundity, and in two or three sections proliferation seemed epidemic. The entire report was full of interest, and even the analysis it deserves would be too lengthy for our columns.

The essay by the third Vice-President, Dr. H. R. Baldwin, had for its subject Diagnosis. He insisted upon the importance of that kind of examination which not merely correctly names the disease, but informs as to stage, degree, and all that precision and accuracy which tends to make of medicine an exact science. Illustrative cases were given, and the value of the ophthalmoscope and other instruments in the close measurement of disease was enforced. The sub-

ject was well treated, and the paper is valuable for future reference.

Dr. WARD, Assistant Physician of the New Jersey Asylum, was the appointed essayist, and read a valuable paper upon insanity.

He discussed with ability its causes, naming hereditary taint and improper methods of education as the two most prominent. Cases coming under his own observation were specified to show how persistent hereditary influence sometimes proved. The influence of higher civilization upon mental disease was discussed. The doctor claimed that true culture in nowise tended to develop mental disease. Although our methods of culture may cause insanity, and although the development of the most highly organized part of the human structure may make it more susceptible, this is counterbalanced by our ability to deal with it with preventives and remedies, which the higher cultivation also furnishes.

The one point especially elucidated as to treatment, was the bearing of wakefulness on all forms of insanity, and the importance of rest and sleep as the great restorers of disordered brain. Where there is tendency to idiocy or change of structure it may not avail; but a large number of cases of insanity are disordered functions, and sleep must be secured at all hazards. The article is an excellent and permanent contribution to the science and literature of our profession.

The essay on Medical Legislation was postponed until next year, on account of the absence by sickness of the appointee. Some interesting discussion was had upon the subject. The importance of sanitary legislation was recognized; but in the present state of popular ignorance as to the claims of scientific medicine, it is not believed that wise legislative protection can be expected from the "average statesman" whether at Trenton, Albany, or Harrisburg.

The meeting was in every way honorable to the profession of the State, both in its social and scientific character, and in the practical effort which the Society makes by its State reports to avail itself of clinical experience in different sections. The presence at the seashore of many of the wives and daughters of medical men did not detract from the enthusiasm of the occasion.

The Society will meet next year at Cape May, and having farther widened its views by ocean scenes, will probably then betake itself to Newton or Morristown, to feed and grow on mountain air. In the meantime, Philadelphia and New York wish all success to their nearest foster-children, the medical profession of New Jersey.

of the sixty whose names were appended to the Protest against the recent action of the Board of Managers of the Presbyterian Hospital.

What possible connection exists between medical advertising and this protest?

Mirabile dictu, Medicus has discovered that these sixty members of the profession desired individually and collectively, one or both, to advertise themselves into notice by publishing their protest, with their names and titles appended, in a public journal.

Now, sir, this implication is too absurd on the face of it to require a reply.

Did it not occur to Medicus, that the sole object of the "sixty members of the profession," to which no "Medicus" should prove recreant, was to maintain the rights and dignity of the profession, and to stamp with their reprobation both the hospital and its managers who infringe these rights, as well as those four members of the profession who endorse the action of the managers by accepting the posts thus disgracefully made vacant?

Medicus would have been pleased if this protest had been confined to "one of the proper channels of communication with the profession,"—one of the medical journals.

Undoubtedly so; this is just what the managers also desired. Any publicity, under the circumstances, has been decidedly disagreeable. "It is a matter of no public interest whatever," has been their cry.

For my own part, I signed the protest without any knowledge that it would see the light further than in the Board of Managers to whom it was directed, and I presume the rest of the sixty did the same; but, for one, I am glad that it has been published in the daily journals, where it may reach the eyes of the public and influence the contributors to our well and ill managed charities—whom it concerns more than the medical profession, and to whom it may afford some indication where charity is *not* best applied.

The statement of Medicus that these four physicians were dropped "for cause," is unworthy of notice, while he and the Board of Managers dare not specify what this cause is; although the same is well known to originate in the old conflict between ignorant nurses and doctors in the sick room, and arrogant, self-conceited "directresses" and the medical staff in hospital wards.

Assuring you of my hearty sympathy and co-operation in your efforts to raise the standard and support the dignity of the medical profession, I beg leave to subscribe myself, with card enclosed,

ONE OF THE SIXTY.

Correspondence.

THE PRESBYTERIAN HOSPITAL AFFAIR.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Without having the pleasure of knowing or even suspecting the name of your correspondent "Medicus," who writes under the head of "Medical Advertising," in the last issue of your journal (May 29th), I cannot but admire his talent in sophistic reasoning, though attempted only by implication.

Medicus "reads with pleasure your editorials on the subject of advertising doctors,"—with no greater pleasure, I am sure, than yours truly, nor than any one

New Instruments.

A NEW VAGINAL SYRINGE.

By W. H. STUDLEY, M.D.,

NEW YORK.

I HAVE met, in my practice, with at least a dozen cases of unmistakable *uterine colic*, produced by vaginal injections. The accident has occurred in the majority of instances by the use of the Davidson, Essex, or Fountain syringe. It arises, undoubtedly, from the small diameter of their female points, their conical shape, the fact that their extremities are pierced with a hole in the centre, and the conjunction of these facts with certain pathological conditions of the os and cervix

uteri. A prolapse of the uterus to a certain extent, by which the vaginal and uterine axes are made to coincide more or less, a retroversion, a patulous os, these and other conditions afford too many and too favorable chances not to be utilized to the production of this mishap, under the use of such instruments as those just alluded to. But it is not alone the *danger* which condemns their employment. They are *inefficient*. In consequence of the smallness of their diameter they fail to distend the folds of the vagina sufficiently,

either for the purpose of reaching thoroughly the cervix uteri or the crypts and the muciferous glands which lurk between the vaginal rugae. The ordinary glass and rubber *piston* syringes, although efficient in the direction of vaginal distension, are to be discarded in the main, because they involve the objectionable necessity of frequent introduction and withdrawal, in all cases, at least, where the desired object is abundant and lengthened injections. And then, too, they are not without their dangers. It is only necessary that one of the orifices of the syringe shall be in juxtaposition and continuity with the cervical canal to insure the accident in question. Another objection to the syringes in ordinary use is that their orifices are flush with the planes of their ends and sides, and the consequence is that all those in contact with the vaginal and uterine tissues are effectually closed to the exit of their contained fluid. These are some, though by no means all, of the objections to the old syringes. I have

made an attempt at a substitute without them. It undoubtedly is not perfect, yet I deem it possessed of sufficient merit to bring to the attention of the profession.

The accompanying wood-cut almost of itself describes the instrument, and obviates any lengthened detail. Its composition is vulcanized rubber. Its diameter is in the smallest size a half inch, in the largest size three-fourths of an inch. It is about six inches in length. Its proximal end is closed by a screw cap, from which juts a tubular projection, on which the rubber tubing of a Davidson, Essex, or Fountain syringe is sprung, or that which conveys the properly tempered water from the Y-shaped or *upsiloid* tube which receives the hot and cold water from their respective hydrants. The distal end is armed with a crucial guard; and in this consists about all that is peculiar to the syringe, and on which I base its chief advantages.

This guard is a jutting out of the same material of which the syringe-barrel is composed, to the extent of fully one-third of an inch from its end, and is a line and a half in thickness. The four right angles thus formed by the guard are coursed with one hole each, about a line in diameter. By means of this guard it is impossible to bring any one of them in juxtaposition with the uterine canal. Hence its absolute safety. By the same means it is impossible that any one of the orifices should be closed by contact with tissue, and hence its efficiency in reaching all parts to which it is directed,—while again, by the same means, an impingement of stream is allowed (issuing as it does from

the syringe fully one-third of an inch from the tissues played upon), which of necessity must contribute greatly to the thoroughness of the douche. I have employed them now for about a year, and with increasing satisfaction.

160 EAST 83D ST., APRIL 14, 1875.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from May 23d to May 29th, 1875.

SLOAN, WM. J., Surgeon.—Announced as Medical Director of the Department. G. O. 29, Department of Dakota, May 4, 1875.

KNICKERBOCKER, B., Assistant Surgeon.—The order directing him to proceed to Fort Colville, W. T., is revoked, and he is assigned to temporary duty at Fort Vancouver, W. T. S. O. 60, Department of the Columbia, May 11, 1875.

Medical Items and News.

UNUSUAL MORTALITY AMONG ELDERLY PEOPLE IN LONDON DURING THE PAST WINTER.—*The Lancet* says: "The winter may be said to have lasted from the middle of November to the end of March. During this period of twenty weeks 37,326 deaths were registered in London, equal to an annual death-rate of 28 per 1,000. In the corresponding period of 1873-4 the deaths in London were 32,378, or only 25 per 1,000. Of this excess nearly 2,000 were of persons aged upwards of sixty years."

A SENTENCE OF DEATH has been pronounced against a man named Graves, who seduced a young lady in Brockville, Canada, and a Dr. Eric B. Sparham, who, at the desire of the former, produced an abortion, causing her death.

COLLEGE OF PHYSICIANS AND SURGEONS, ONTARIO.—Out of one hundred and twenty candidates who entered their names for examination at the last commencement, fifty-eight passed and obtained licenses to practise. Among the number was Mrs. J. K. Tout, of Toronto. She is the first lady who has obtained a license to practise medicine in all its branches in Ontario.

THE NEW LYONNAISE SCHOOL OF MEDICINE AND PHARMACY.—The Municipal Council of Lyons have appropriated one million francs for the construction of the newly established school of medicine and pharmacy, and negotiations are at once to be opened with a view to the organization of a faculty.

PROSTITUTION IN BUENOS AYRES.—Buenos Ayres has established a law governing prostitution, which resembles in its general characteristics the laws adopted in other countries, viz., in requiring an examination of the registered prostitutes; imposing fines on clandestine prostitutes and upon men who cohabit with them; and the absence of any inspection of the physical condition of men resorting to houses of prostitution.

RESECTION OF THE SCAPULA.—Dr. Vuzengo Omboni reports in the *Raccoglitore Medico* the complete removal of the scapula for a medullary osteo-sarcoma, followed by survival of what remained of the patient. The doctor claims this to be the fourth case of removal of the scapula in Italy.

NEW AIDS TO DIAGNOSIS.—At Rome a conference of the medical clinic of the University was held on the 18th of April, to hear Dr. Collengues explain the mechanism and working of three new instruments devised by him, and entitled the pneumoscope, the dynamoscope, and the bioscope, which promise to be of some use in the practice of medicine. With the former may be produced artificially all the abnormal murmurs proceeding from the respiratory organs in a state of disease; with the dynamoscope may be determined the scale of all the sounds which are made at the digital extremities by continuous movement of the tissues; while the bioscope registers with precision the heat, the electricity, and the functional activity of the skin.

ETHIOPS MINERAL.—Prof. Cadet states that the vapors of the sulphuret of mercury have been efficient in protecting from the paludal fever of the Campagna, etc. Equal parts of mercury and flowers of sulphur are boiled in water, in a room, in such quantities that the vapor is not unpleasant.

VIVISECTION IN ENGLAND.—The result of the agitation of the subject of vivisection in England has resulted in the arrangement of the terms of a bill in Parliament which, it is expected, will prevent any unnecessary cruelties or abuse in experiments made on living animals for purposes of scientific discovery. Another bill, known as Lord Hutton's, has also been introduced, which is, in the main, prohibitive of experiments and destructive of physiological research; and still a third bill, under the auspices of the Society for the Prevention of Cruelty to Animals, which is but little better than the last mentioned.

CHOLERA IN INDIA.—It is reported that cholera has again reappeared in that portion of India where, for seven years past, it has proved fatal to so large a proportion of the population. The disease has also appeared in Ceylon, where, in Colombo, out of four hundred and five cases, two hundred and eighty-eight proved fatal.

MONUMENT TO MORGAGNI.—A monument was to have been erected on the 27th of May, to John Baptist Morgagni, the great anatomist, pathologist, and clinical teacher, by his native town of Forlì, in Italy. The town council invited to the ceremony all the medico-chirurgical academies and faculties in Italy, and the principal medical bodies of other countries.

A CHARGE OF MANSLAUGHTER has lately been made, in Lincoln, England, against a Dr. Wood, who was called to attend a woman whom he found to be flooding. The case seemed to have been one of placenta prævia, and the doctor delivered at once. After remaining for what he considered a reasonable time after the delivery the doctor left, and in an hour thereafter was recalled, owing to the patient becoming worse, and found her dead from collapse. A *post-mortem* examination disclosed a ruptured uterus, but the medical evidence exculpated the doctor from all blame in the conduct of the delivery; and the question urged in the court relates to the length of time the doctor remained after the child was born.

THE ROCKLAND CO. MEDICAL SOCIETY, at its annual meeting, held at New City, on the 25th of May, elected the following officers for the ensuing year: *President*, Dr. C. H. Martin; *Vice-President*, Dr. G. A. Lockwood; *Secretary*, Dr. William Govan; *Treasurer*, Dr. Henry H. House; *Librarian*, Dr. J. S. Wigton; *Censors*, Drs. J. S. Wigton, J. O. Polhemus, and O. J. Wells.

MALPRACTICE.—A surgeon named Peacock, of Neaton, a suburb of London, has lately been convicted and sentenced to six months' imprisonment for having cut away a quantity of intestine which protruded from the vagina of a woman whom he had delivered with forceps of her eleventh child, and who had suffered a rupture of the uterus. The impression among his professional brethren is that the rupture may have occurred spontaneously, and he is thought to have committed an error in judgment in a position of great difficulty and responsibility. The doctor has borne an excellent character as a student and practitioner, and efforts are being made to secure a remission of the sentence of imprisonment.

A MEDICAL LAW IN NEVADA.—Nevada has a "Medical Law" which went into effect on the 28th of March, and which makes it a misdemeanor for any person to practise medicine without a diploma certifying to a proper medical education.

DECEASED.—On May 25th, Dr. John A. Ford, aged sixty-three.

On the same date, Dr. William W. Hedges, aged eighty-five, at Chester, Morris Co., N. J.

On the same date, Dr. John Stark, aged fifty years, of this city.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA will hold its annual session at Pottsville, on Wednesday, June 9th.

HOMEOPATHY IN THE ANN ARBOR SCHOOL.—It is reported that the homeopathic lectures on therapeutics and practice in the Michigan University are to be delivered at the same hours as those on the like subjects in the "antipathic" branch of the school.

THE PLAGUE IN MESOPOTAMIA.—The *Liverpool Herald* announces the appearance of plague in the district of Dinanish, on the lower Euphrates. The disease appears to be scattered over a wide extent of country, and in the same localities where it existed last year. From the Hindeh Canal, near Hillah, to Samava, both banks of the Euphrates are occupied with a series of vast marshes, the islets of which are inhabited by Arab tribes. In 1867 the Hindeh marshes, after many years' absence of the plague from the district, became the scene of an outbreak of the disease. Early last year the marshes on the opposite (the east) bank of the river, occupied by the Affj Arabs, were the locality of an outbreak which is supposed to have caused the death of four thousand people.

INCREASED FATALITY OF PUERPERAL FEVER IN LONDON.—The fatal cases of this disease registered within the limits of London in 1871 were but 182. During the three succeeding years they increased to 251, 306, and 456 respectively. During the first thirteen weeks of this year eighty-two deaths were referred to this cause, which, although exceeding by fourteen the average number during the corresponding period for the last ten years, were forty-one less than in the first quarter of 1874. The disease now exists in an epidemic form in many localities of London.

ANOTHER TRAINING-SCHOOL FOR NURSES.—The Commissioners of Public Charities and Corrections have passed a resolution to establish, on Aug. 1, at the Charity Hospital on Blackwell's Island, a school for nurses. The term of instruction is to be two years. Persons between the ages of 20 and 35 years are to be instructed, who are to be paid \$10 per month for the first year, and \$15 per month for the second year.

EXAMINATION OF THE EYES OF SCHOOL CHILDREN.—One of the most interesting as well as important of the papers read at the recent meeting of the American Social Science Association, at Detroit, was by Dr. Webster, assistant to Prof. C. R. Agnew, of this city, and contained the statistical results of examinations made of the vision of school-children in Brooklyn, Cincinnati, and New York. In these cities, the eyes of 2,884 scholars of both sexes, ranging in age from six to twenty-six years, had been examined, and the conditions as to refraction and disease noted. At the same time, the state of the school-rooms, as regards light, desks, heating, and ventilation, was observed, as well as the length and distribution of the time devoted to study, and other facts which might affect health.

Drs. Ayres and Williams examined the eyes of 1,264 scholars in Cincinnati, one-third of whom attended district schools, one-third the intermediate, and the remainder were pupils in the normal and high schools. In the district schools 13.3 per cent. were near-sighted (11.3 per cent. of the boys and 15.3 per cent. of the girls). In the intermediate schools 13.8 were near-sighted (9.5 per cent. of the boys and 18.1 per cent. of the girls). In the normal and high schools 22.8 per cent. were near-sighted (22.2 per cent. of the boys and 23.2 per cent. of the girls).

Drs. Prout and Mathewson examined the eyes of 600 students at the Polytechnic, in Brooklyn, all of whom were boys, 284 belonging to the academic and 316 to the collegiate department. Of the former 9.2 per cent. were near-sighted, and of the latter 21.8 per cent.

Dr. Cheatham examined the eyes of 1,020 boys in the College of the City of New York: 670 belonging to the introductory class, 210 to the freshmen, 110 to the sophomores, and 30 to the juniors. In the introductory class, which is made up entirely of students who have passed the public schools, 21.9 per cent. were near-sighted; of the eyes of the freshmen, 26.2 per cent. were near-sighted; of the sophomores 22.7 per cent., and of the juniors examined 50 per cent. were near-sighted, although of the juniors the number examined was too small to be of any scientific value.

The tables which were based on these observations show that staphylocoma posticum, one of the gravest organic changes in progressive near-sightedness, increased from 0.5 per cent. in the district schools to 7.6 per cent. in the intermediate, and 10.4 per cent. in the normal and high schools. In one of the large schools, in which a careful ophthalmoscopic examination was made of every scholar, out of about 1,000 scholars the eyes of 703 were found to deviate otherwise than in refraction from the normal standard.

REQUESTS TO PUBLIC CHARITIES.—The late Don Alonzo Cushman left the following amounts to charitable institutions in this city: Orphan's Home of the Protestant Episcopal Church, \$1,000; St. Luke's Hospital, \$2,000; New York State Woman's Hospital, \$500.

The late Mr. Denistoun leaves to the Presbyterian Hospital between forty and fifty thousand dollars, and the same institution will probably receive a very large amount from the estate of the late John C. Green.

The will of the late Albert Fearing, of Boston, makes the following bequests: To the Children's Mission to the Children of the Destitute, and to the Children's Hospital ten shares each of the capital stock of the Lawrence Duck Company, the par value of which is \$1,000 per share, and what is left after certain other bequests have been paid and the estate has been settled.

A NEW FORM OF GLYCOSURIA.—M. Jules David has recently observed in a case of diabetes following a large carbuncle, a substance resembling glucose in its reactions, but differing from anything hitherto discovered. The urine reduced Fehling's solution, although less readily than ordinary diabetic urine. Liquor potassæ also caused a brown discoloration. But on examining it with the polarizing saccharimeter, not the slightest trace of deviation could be discovered. Moreover, on analysis, no glucose whatever was found by the usual method. A solution of the substance, after isolation, reduced Fehling's solution readily. Its exact nature has not yet been determined, owing to failure of the supply of urine.

NEW YORK HOSPITAL.—A bill has passed the Legislature and received the signature of the Governor, which exempts from taxation all the property of the corporation actually used for hospital purposes.

THE FLOATING HOSPITAL OF ST. JOHN'S GUILD.—The Treasurer of the Guild acknowledges the receipt of \$6,975 for the fund to establish the floating hospital, and says that over thirteen thousand more will be required to complete the hospital barge.

BARNUM'S FAT WOMAN.—Mrs. Rohn—died in Baltimore, on the 28th of May, aged twenty-nine years. She was born in Licking Co., Ohio, and at the time of her death was six feet and four inches high, seventy-two inches in circumference about the waist, and weighed five hundred and eighty-three pounds.

THE NEW YORK DISPENSARY FOR NERVOUS DISEASES is the name of an institution opened on the 31st ult. at 155 East Twenty-sixth Street.

PROFESSOR TRAUBE, of Berlin, has so far recovered his health that he is able to resume again this summer his clinic.

A NEW HOSPITAL FOR BALTIMORE.—The cornerstone of the new building for St. Agnes Catholic Hospital, three miles from the city of Baltimore, was laid on the 30th ult.

DR. JOHN C. BUCKNILL, well known as an English writer on insanity, is visiting the United States.

THE JEFFERSON MEDICAL COLLEGE have bought land adjoining the college for the purpose of erecting a hospital.

THE UNIVERSITY OF PENNSYLVANIA has received a bequest from the late Mr. John Fowne, of \$10,000 towards its hospital fund.

SUSPENSION OF THE ANDERSON SCHOOL OF NATURAL HISTORY.—Alexander Agassiz, Director of the Penikese Island School, announces that pecuniary considerations oblige the closure, for the time at least, of this valuable school.

PROFESSOR HITZIG, of Berlin, is to take charge of the Lunatic Asylum in Zurich, Switzerland.

WEEKLY BULLETIN OF THE MEETINGS OF MEDICAL SOCIETIES.

Monday, June 7.—N. Y. Ophthalmological Soc.

Tuesday, June 8.—American Microscopical Soc., Yorkville Med. Ass'n.

Wednesday, June 9.—N. Y. Pathological Soc.

Thursday, June 10.—N. Y. Laryngological Soc.; Brooklyn Pathological Soc.; Jersey City Pathological Soc.

Friday, June 11.—Medical Library and Journal Assoc'n; Harlem Medical Assoc'n.

Original Communications.

THE OPHTHALMOSCOPE AS A CEREBROSCOPE.

By CHARLES S. BULL, A.M., M.D.,

OPHTHALMIC SURGEON TO CHARITY HOSPITAL; ASSISTANT SURGEON TO THE N. Y. EYE INFIRMARY; PATHOLOGIST TO THE MANHATTAN EYE AND EAR HOSPITAL.

DURING the past year there have appeared many articles in domestic and foreign medical journals, upon the ophthalmoscopic signs of intracranial disease, and the ophthalmoscope has been lauded to the skies for the many discoveries it has made, and for the great and varied services it has rendered to the science of medicine in the vast domain of cerebral pathology. The little instrument has perhaps found its most ardent advocates among that class of medical men who have taken it up as an adjuvant to the diagnosis of diseases of the cerebro-spinal nervous system, and by certain members of this class the powers of the instrument have been extolled beyond all reason. Ophthalmologists as a class deprecate this almost limitless extension of the claims thus put forward, and it is the object of this paper to endeavor to state plainly how far the ophthalmoscope will really aid us in the diagnosis of diseases of the brain and spinal cord.

The claims of the ultra advocates of the ophthalmoscope may be best set forth by a statement of the views of M. Bouchut, who has devoted many years to the study of diseases of the brain and spinal cord in children. He lays down four laws for the formation of intra-ocular lesions depending on diseases of the brain, spinal cord, and meninges, as follows: 1st. Whenever the circulation is obstructed in the cranium, or in the sinuses or meningeal veins, in consequence of compression through distension of the ventricles by serum, or any other cause, an arrest of the venous circulation occurs, which produces swelling, hyperemia, and œdema of the optic papilla; varicosity of the retinal veins, and sometimes hemorrhage into the eye; 2d. When a cerebral tumor with general or partial encephalitis is present, a descending phlegmasia occurs, which brings on sclerosis of the optic nerve, exudations which compress and imprison the optic papilla, and eventually produce atrophy of the same; 3d. If it be the spinal cord which is diseased by anterior or posterior sclerosis, since that organ, on account of its relations with the great sympathetic nerve, acts on the eye, papillary hyperemia of the eye results, which in time brings on atrophy; this is seen in locomotor ataxy; 4th. Finally, in all diatheses and poisonings of the general system, when the whole organism suffers, the eye suffers like the rest of the body, and certain forms of neuritis and choroiditis result.

In a subsequent paper M. Bouchut writes as follows: "Whenever the brain or spinal cord is seriously diseased, the lesion is propagated to the eye, and appears in the optic papilla, retina, or choroid, giving rise to neuritis, or neuro-retinitis, or choroiditis, which must be recognized in order to determine their significance. This is a true *cerebroscopy*, that is, a means of seeing in the eye what is going on in the brain." The italics in the above passage are my own.

M. Bouchut further recognizes four forms of neuritis in cerebro-spinal diseases, viz.: 1st. A mechanical neuritis by obstruction and arrest of the meningeal circulation; 2d. A descending neuro-retinitis, occurring in acute and chronic encephalitis, and in intracranial tumors; 3d. An ascending neuritis, which he regards

as the reflex of spinal diseases by a paralysis of the vaso-motor action of the great sympathetic nerve; 4th. A diathetic neuro-retinitis or neuro-choroiditis, depending on some constitutional taint, as struma, syphilis, leucocythæmia, diabetes, etc. In the tuberculous diathesis, Bouchut says there exists serous infiltration of the papilla, partial steatosis and fatty granulations of the retina complicated by tubercles of the choroid.

Let us now return to the consideration of, these four laws. The first law states that whenever there is an obstruction to the intracranial circulation, from whatever cause, there results an arrest of the circulation of the optic nerve and retina, which produces hyperemia and œdema of the papilla, varicosity of the retinal veins, and sometimes hemorrhages into the retina; in other words, we have a "choked disk." This is the view promulgated by Von Graefe, to account for the symptoms which he grouped under the name of "stannungs-papille," or choked disk. But of late this explanation has been controverted by some able ophthalmologists as insufficient. The cavernous sinus, into which is emptied the venous blood coming from the eye, is surrounded by unyielding walls, which do not admit of compression, and it is difficult to see how an obstruction in the circulation of the brain, at some distant point, could react upon a canal with rigid walls, unless the resulting intracranial pressure were very great. Cases of such extreme increase of intracranial pressure are rare, while choked disk is by no means an uncommon symptom of cerebral disease. A very able paper, by Dr. Loring, of this city, was recently read before the New York Society of Neurology and Electrology, which stated the case very plainly and satisfactorily, being based on anatomical and physiological facts. Another theory has been advanced to account for these intra-ocular manifestations, by Benedikt, several years ago. He holds that "choked disk," and even neuro-retinitis descendens, depend on a neurosis of the fibres of the sympathetic nervous system, a morbid innervation, which is a concomitant of many intracranial morbid processes. The peculiar disposition this shows to manifest itself in the optic papilla he explains by the anatomical fact that the blood-vessels of the retina perforate the rigid fibrous sclerotic coat, through the lamina cribrosa. When an active hyperemia with swelling appears, the egress of blood from the eye is hindered; there is stasis, dilatation of the vessels, and growth of connective tissue, and finally, in consequence of the diminished circulation and swelling of the connective tissue, the case ends in atrophy of the vessels and nerve-fibres, and amaurosis is the result. From the known intimate connection between the sympathetic nervous system and the cerebro-spinal axis, morbid processes in the spinal cord or brain exert more or less influence on the sympathetic fibres, and through them on the vessels and other organs under their sway, and hence this theory of Benedikt's is a plausible one, and is perhaps of equal value with the theory by mechanical obstruction of Von Graefe, since it has not been proved to be false or insufficient. The causation of choked disk, however, is as yet an unsettled point, which future pathological investigations must decide.

M. Bouchut's second law is, that when a tumor with general or partial encephalitis is present, a descending phlegmasia occurs, which involves the optic nerve and ends in atrophy. Taking this statement in connection with a subsequent one, that grave lesions of the brain always cause lesions of the optic nerve, retina, or choroid, the whole ground seems to be covered. But the fact is that very many cases are on record in which not only tumors of the brain, but meningitis also, were

diagnosed, in which, throughout the whole course of the disease up to the fatal termination, not a single abnormal ophthalmoscopic sign manifested itself, and yet the autopsy confirmed the diagnosis of grave cerebral lesions. Many of these cases have been under the care of skilful ophthalmologists, and were carefully and frequently examined. I have seen within the past year three cases of grave cerebral lesion, where a diagnosis of intracranial tumor was confirmed by the autopsies, and yet not a sign of neuritis, or choked disk, or any abnormal appearance in the eyes presented itself.

A meningitis on the convexity of the cerebrum would probably not manifest itself in the optic nerve unless the inflammatory process had extended to the base of the brain. It is very evident that grave lesions of the brain do not always cause lesions of the optic nerve and retina, and, of course, when they are not to be seen, the ophthalmoscope will not help us. When there is a choked disk or a neuro-retinitis with exudation, then the ophthalmoscope points to some intracranial lesion, and may sometimes, in connection with other symptoms, help us to locate the disease, but not always. Moreover, we are by no means sure that the lesion is a tumor or a meningitis, or a cerebral abscess, from mere ophthalmoscopic examination. A choked disk is as often caused by a basilar meningitis as by a cerebellar or any other tumor.

The third law states that when the spinal cord is diseased from sclerosis or other pathological processes, on account of its relations with the great sympathetic nerve, the spinal lesion reacts on the eye, causing papillary hyperemia, which ends in atrophy of the optic nerve, as is seen in locomotor ataxy. This statement is partly true, and partly false. In locomotor ataxy, the sclerosing process is very apt to occur simultaneously in the brain and optic nerves, and sometimes the lesion in the nerves of vision antedates by years the disease in the cord; but not a few cases of ataxy progress to a fatal end without ever showing any lesion in the optic nerves.

As regards other diseases of the spinal cord, ocular complications are not common, and in one of the most frequent, Pott's disease, the participation of the optic nerve stops at hyperemia, and *never* advances to atrophy.

The fourth law of M. Bouchut is open to the same objections as the third; it is partly true and partly unwarranted. Syphilis attacks the retina and choroid very frequently, as do less frequently leucocythæmia and diabetes. As regards the tuberculous diathesis, the proportion of cases of general tuberculosis, or of tubercular meningitis, or of pulmonary tuberculosis, in which tuberculous deposits are found in the choroid, is very small indeed, and in fact any lesion of the retina or optic nerve in a tuberculous patient is not commonly met with. In speaking of the different forms of neuritis occurring in intracranial disorders, M. Bouchut mentions an *ascending* neuritis, which he regards as a reflex of the spinal lesion, resulting from a paralysis of the vaso-motor action of the great sympathetic nerve-fibres. If the word *ascending* refers to the direction of the inflammatory process in the nerve-fibres of the spinal cord, it is correct; but if it refers to the process in the optic nerve-fibres, it is quite faulty. An *ascending optic* neuritis is a process which starts from the distal or ocular end of the optic nerve, and ascends towards the brain or centres of origin of the optic nerve. A direct connection between sclerosis of the spinal cord and sclerosis of the optic nerve by continuity of tissue is very rarely met with at autopsies. In Pott's disease, where the degenerative or sclerosing process extends in both directions, upwards in

the posterior columns and downwards in the anterior columns of the cord, we are very apt to meet with minor changes in the circulation of the optic nerve and retina. Now in this disease there is no extension of the morbid process to the brain or ganglia at its base, and the changes that we do see in the eye must be explained by a propagation of the morbid influence from the cord through the vaso-motor nerves to the vessels. But there is no inflammation or atrophy of the optic nerve-fibres.

By means of the ophthalmoscope we have unravelled the mystery of the old-time amaurosis, and have dissipated the shadows which formerly hung around all lesions of the deeper tissues of the eye. If the media of the eye are clear, all lesions of the optic nerve, retina and choroid, and many of the morbid processes within the brain may be diagnosed without hesitation, and without the possibility of making a mistake. The different forms of retinitis and choroiditis may be differentiated from each other; and from the repeated occurrences of retinal hemorrhages, we may even prognosticate with some degree of certainty the occurrence of cerebral apoplexy. Tumors at the base of the brain, in the ganglia at the base, in the cerebral lobes, and even in the cerebellum, if of considerable size, will *generally* set up either a descending optic neuritis or produce the signs of "choked disk," but they will not do so always. Basilar meningitis, if anywhere near the median line or at all extensive, will always give us the same intra-ocular manifestations as tumors, that is, neuritis or choked disk. The ocular manifestations of cerebral lesions are almost always double, both eyes being involved, though not always to the same extent. But unwilling as we are to admit it, the ophthalmoscope as a *cerebroscope* is of limited extent; the more hopeful would perhaps say it is still in its infancy. There are many forms of amblyopia, and even of amaurosis, some transient, others permanent, which present actually not a single abnormal ophthalmoscopic symptom. The media remain clear, the optic nerve retains its clearly defined, rosy hue, the vessels are unchanged in appearance or calibre, and the retina is still transparent, and yet the patient does not see. There may be symptoms pointing to cerebral trouble, but these may be entirely absent, and we examine such patients day after day and see absolutely no change. Take, for instance, the attacks of dimness of vision occurring in persons suffering from chronic renal disorders. Perhaps the first symptom of any constitutional disorder is a failure of the vision—a dimness, as if a veil were drawn over the eyes. This lasts a variable time and then disappears, but recurs again and again, and the patient comes to us for examination. The ophthalmoscope is used, and the fundus of the eyes found absolutely normal; the examination is made repeatedly and carefully, and still nothing is seen. But the patient develops more constitutional symptoms; chronic renal disease is suspected; and finally, though by no means *always*, a peculiar, stellate exudation in the retina is seen, a fatty deposit in the region of the macula lutea, which until recently was supposed to be due *always* to chronic Bright's disease, but we now know that it is met with in other forms of retinitis, not dependent on renal disease.

The vision now becomes gravely and permanently impaired, and we have to deal with a retinitis or a neuro-retinitis albuminurica, to be clearly and rigidly distinguished from the preceding transient dimness of vision, which we term uremic amblyopia; this is due to the poisoning of the nerve-centres by the urea circulating in the system. Here again the ophthalmoscope comes into play in its great rôle of differential diag-

nostician. We owe more to it than any one instrument, not even excepting the stethoscope, but we cannot do everything with it, and its great value can only be duly appreciated by those who know just how far it will surely aid us, and where to draw the dividing line beyond which we leave the firm ground of proven facts, and enter the broad realm of pure speculation, where oftentimes the wish of the observer is father to the thought. Enthusiasm *per se* is a wonderfully energetic agent in the cause of science, and when not guided by calm judgment, impels the investigator almost resistlessly into a region beyond the limits of observation and experiment; and this tendency is particularly pernicious when exhibited by observers who have a certain weight of authority in the medical world. Of course the more widely facts are spread after they have been proved to be true, the better for all of us, patients as well as physicians, but it is not well when any one observer attempts to speak *ex cathedra*, and to lay down rules for the guidance of his contemporaries at large, when such rules are unsound. The promulgator of such views, I think, incurs a grave responsibility, but this responsibility also falls with perhaps equal force upon the shoulders of all observers and students of science, who know that such views are extravagant and unsupported by facts, and yet by their silence not only fail to protest against, but tacitly concur in their extension.

214 WEST 44TH ST., May, 1875.

ON THE TREATMENT OF ACUTE NASAL CATARRH, ETC., BY THE TINCTURE OF THE CHLORIDE OF IRON.

A SECOND NOTE.

By J. S. PROUT, M.D.,
OF BROOKLYN, N. Y.

IN the MEDICAL RECORD for Jan. 1, 1874, page 8, will be found a communication from me on the success attending the treatment of coryza by large doses of the official tincture of the chloride of iron.

Since then my experience has been as there recorded: some cases yield immediately or speedily to its influence, others (more severe) are relieved to a partial degree only, and a few seem not to be affected by it.

How is this curative influence to be explained? It is well known that the tincture of the chloride of iron administered internally, is considered by many to be almost a specific in erysipelas. I consider the inflammation of the mucous membrane in acute pharyngitis, coryza, or frontal catarrh, similar in character—diffuse or non-circumscribed. I have seen cases of facial erysipelas that seemed to result from an extension outward of coryza, pharyngitis, etc., not, however, passing out by mouth or nose, by continuity of tissue, but as if by direct transmission through the intermediate tissues.

But, however the effect is produced, there is very often an abortive action on the inflammation; in half an hour relief may be felt, which may remain permanent, or a cure may require a few repetitions of the dose.

My practice is of such a character that I do not see many cases of *colds*. I am glad, therefore, to be able to give the experience of others.

Dr. C. S. Bull, 214 W. 44th Street, New York City, writes as follows: "I have used the tincture of the sesquichloride of iron quite frequently in cases of recent or incipient nasal catarrh, what is ordinarily called 'a cold in the head,' and almost invariably with a rapid beneficial effect. I give it as soon as the patient com-

plains of the sense of fullness in the nose and head, in doses of from ℥ xx. to ʒ ss., and repeat every hour; usually I have not been obliged to give more than four or five doses, and sometimes not more than two. I have taken it myself, and always with good results. But it must be given early, otherwise it fails in producing the desired effect. I have not noticed any bad effects from its use in such frequently repeated doses."

Dr. N. B. Sizer, of 336 Greene Ave., Brooklyn, has during some time past made brief notes of cases of coryza treated by tincture of the chloride of iron, and recorded his results. He has left unrecorded a number of ordinary cases of cold in the head, neither severe nor annoying to the patient, in all of which, according to his recollection, relief was prompt and decided. His results are as follows:

"Number of cases recorded, 28. Age of youngest, 3 months; of oldest, 63 years.

"Results—Cured in—24 hours	10
" 36 "	12
" 48 "	3
Much relieved but not cured	1
Symptoms alleviated but not cured	2
	28

"In those not cured the catarrhal inflammation was modified somewhat, but the disease ran its usual course. There was no personal idiosyncrasy, as far as known, to interfere with the curative results in these last cases, and the cause of failure is unknown.

"The dose varied from 3 to 35 minims, with an equal amount of syrup or glycerine. The 30-minim dose has been given to an infant, with wonderfully quick effect, done tentatively, however, and not as a usual thing.

"There would seem to be no doubt, as far as my observation goes, of the generally excellent effect of the tincture in these cases."

The tincture should be largely diluted with water, and taken through a glass tube or straw so as to protect the teeth. Its effect is more pleasant if the stomach is not entirely empty.

The tendency of the iron to constipate may be very much lessened or entirely prevented by the addition of three or four drops of the tincture of belladonna to each dose.

THE DIAGNOSIS OF INSANITY.

By EDWARD C. MANN, M.D.,

MEDICAL SUPERINTENDENT, STATE EMIGRANT INSANE ASYLUM, WARD'S ISLAND, NEW YORK.

THERE is probably no disease which presents greater difficulties in the way of diagnosis than insanity. In most diseases we examine physical signs and symptoms, and we determine by our senses the existence of such diseases. In insanity, on the contrary, we have to be guided chiefly by our knowledge of the normal functions of the mind, and in our examination we have to rely on our intellect rather than on our senses, although of course the latter are called in to assist us. It is, however, very often extremely difficult to decide with certainty, as we are expected to do, as to the existence of mental disease, and we assume a great responsibility, whichever way our decision may be given. We either give the patient liberty to take his place in society, and thus expose society to the consequences if he prove to be insane, or we place him in confinement in some institution for the treatment of the insane, thus depriving him of his liberty and his family of his sup-

port. It becomes, then, a matter of great importance to decide rightly as to the existence of mental disease, for if this is not properly done, we shall expose ourselves to the risk of great mortification, and also to the loss of professional reputation. Before going to see a patient who is to be examined for the existence of insanity, it is advisable to find out all one can from the friends and relatives; but in accepting such statement, it is wise to allow a wide margin for their information in regard to hereditary predisposition, as most people, foolishly considering the existence of insanity in their family a disgrace, will pertinaciously conceal and deny this fact both from themselves and from their medical adviser. Another reason for this concealment may be, that the members of such families are not infrequently odd and eccentric in their behavior, even when perfectly sane, and do not care to have their peculiarities attributed to hereditary taint of insanity, and therefore endeavor to mislead their physician on a point which is to him of the utmost diagnostic importance. Indeed, this and the question of previous attacks are perhaps the two most important points in the diagnosis of any given case.

We should endeavor, when we are called to our patient, to gain his confidence, and from a general conversation lead him cautiously to his state of health and mental feeling. If we are abrupt and wanting in tact we shall probably defeat our object, and the patient, if displeased, will either refuse to listen to or answer our questions, or will become very angry at our conspiring to deprive him of his liberty. If we are fortunate enough to get a history of the patient, we can generally determine easily the existence or non-existence of insanity, by the patient's appearance and conversation. Many times, however, we have to rely alone on the conversation, general appearance, and conduct of the patient, unaided by any other resources. After having gained our patient's confidence and having drawn him into a pleasant conversation, we should first inquire about previous attacks, then into his hereditary history, then into any predisposing causes, such as intemperance, vocation, habits, etc., which may have operated in the production of insanity. Also as to injuries to the head or spine which may have occurred, sunstroke, etc. We should then systematically, but carefully and cautiously, examine into the vegetative and reproductive functions, and then carefully examine the nervous system for the existence of any lesions such as paralysis, epilepsy, catalepsy, hysteria, and allied affections. We should next examine the different senses, beginning with sight, and in this way we shall find out if our patient has good vision, if the retina is normal, and, what is more important, we may discover if he has hallucination or illusions pertaining to this sense. We may then proceed to the sense of hearing, examining for deafness and also to discover any hallucination or illusions of hearing. Proceeding to the sense of smell we shall discover if it is normal, and also if there are any hallucinations or illusions connected with it. Taking up the sense of taste, we may inquire as to the existence of hallucinations or illusions. Patients often complain of their food being poisoned, or that they are eating injurious and hurtful things with their food. The last of the senses, that of touch and nervous sensibility, may be examined for imaginary sense of pain, the existence of reflex action, hyperaesthesia, and lastly, for hallucinations and illusions pertaining to this sense or referring to internal organs of the body. The mental symptoms unconnected with the special senses and pertaining to the intellect, the emotions or the will, may finish the examination.

Whether the diagnosis of insanity presents itself to

the physician in a purely medical or in a medico-legal point of view, the principles of diagnosis are the same, and we must pursue our examination in precisely the same manner. The first thing we are generally called upon to decide is, whether the patient can be treated at home or whether it is necessary to place him in an asylum, and we are also probably asked for a prognosis, which latter cannot be too guarded, whatever may be our own impression at the time about the patient. Let us consider for a moment the first question, that of the propriety of removing our patient to an asylum. Insane patients are, by the very nature of their disease, inclined to do mischief. They are controlled in their actions by delusions that are to them vivid realities, and no one knows what they may consider it right and proper to do, when they are under the influence of such delusions.

Some of the most fearful crimes have been committed by those who had previously been regarded as harmless patients, and no one therefore should take upon himself the responsibility of advising that a patient whom he is called to see should be kept at home. The mere moral effect of a residence in a well-regulated asylum for a time, at the onset of insanity, has an immense effect on the mind of a patient, and may prevent, perhaps, consequences that might prove most disastrous, were he to be at home and exposed to the many causes of excitement from which he is sheltered in an asylum. We must also decide what form of insanity the patient is laboring under, and in a medico-legal case must give our diagnosis as to the insanity of the patient in its relation to his civil capacity and responsibility for criminal actions, and also as to feigned and concealed insanity. In this latter class of cases, medico-legal cases, it is of the utmost importance for every physician to understand that a man is not irresponsible for crimes which he commits from the fact that some of his ancestors have been insane. The question to be determined here is whether the hereditary taint, by being transmitted to the individual in question, has influenced or determined at all his volitions, impulses or acts. If on the one hand he has been noticed for displaying such peculiarities as usually proceed from hereditary taint, and if the crime was apparently unaccompanied by any adequate incentive, doubts of his legal guilt are then to be carefully considered. On the other hand, if the criminal act appears to have been rationally performed, and with some adequate and usual incentive, and if the individual has previously been free from mental infirmities or peculiarities that might be attributed to hereditary transmission, then we cannot justly advance insanity as a plea for defence from the consequences of crime. The diagnosis of insanity is at times very easily made. Thus if we find our patient, from having been previously moral, affectionate and industrious, has become immoral and dissolute, exhibits alienation of affections, and neglects his business, all without adequate cause, it is of course easy to determine his insanity, although of course changes may take place in the character of individuals without any suspicion of insanity being excited. A great many cases, however, are on the border line which separates sanity from insanity, and it often requires the nicest discrimination to determine whether such a patient shall be placed under treatment or not. It now remains to consider the diagnosis of the different forms of insanity which we meet with. In mania the physiognomy is generally distinctive. The countenance is furrowed, the eye wild and vacant, and there is generally a peculiar want of agreement in the expression of the features. The hair often becomes harsh and bristling, and the ears may

become shrivelled. The actions, demeanor, and dress of an insane patient are generally indicative of mental peculiarities, and oftentimes the latter may be indicative of the nature of the patient's delusions, or, if not, it may display marked eccentricity. In acute mania it is generally easy to discern in the countenance the presence of some strong emotional characteristics, such as pride, hatred or anger. It has been remarked that insanity anticipates the effects of years, and prematurely imprints upon the countenance the facial lines characteristic of habitual emotions, while in lunatics of advanced age these are observable in a greater degree, and are more deeply marked than they ever are in sane persons. In this form of insanity the bowels are generally constipated, the urine is loaded with phosphates, and the patient suffers from that protracted loss of sleep which is diagnostic of acute mania, and which is a symptom that cannot be feigned by an impostor. Patients of this class pass several days without sleep, and sometimes weeks with but a few hours of sleep in the course of the whole time. Hallucinations of sight and hearing are far more frequent in this than in any other form of insanity. There may be also rapidly changing delusions, and there is generally an intense muscular restlessness, which manifests itself either in destructive impulses, or in continual motion, which rapidly induces dangerous exhaustion, if not properly treated. In melancholia the most noticeable symptoms will be despondency, fear and despair, and the expression of their mental states are depicted in an unnatural degree of intensity upon the countenance of the patient. The patient generally wishes to be alone, is gloomy and depressed, has delusions of fear and persecution, imagines he has committed unpardonable sins, and in the acute cases of melancholia no more pitiable spectacle can be imagined, and the expression of terrible apprehension and fear which occupies the countenance is not easily forgotten. The skin is generally dry, harsh and muddy, and the bowels constipated. It is such cases as these which have to be carefully watched, lest they give way to the suicidal tendencies which are generally present. In dementia, the lines of expression are more or less obliterated, and the vacant, meaningless expression and smile or laugh are indicative of this form of insanity. When the mind is tested, the power of memory, attention and comparison will be found to be partially or entirely wanting. It is only in primary dementia that the practitioner will find difficulty in reaching a decision, and sometimes these cases are very difficult to determine. In such case, one of the most valuable symptoms is loss of memory. The patient may, in his conduct and conversation, exhibit no marked peculiarities, but when the powers of his mind are tested as to the recollection of past events, or even as to the conversation of a few minutes previous, it will be found that he has entirely forgotten these things. This form of insanity is generally unaccompanied by hallucinations or delusions, and is nearly always due to some exciting cause, such as injuries to the head, and attacks of apoplexy and strong emotional disturbances. There is another variety of dementia which is secondary to acute attacks of insanity, and which differs somewhat from primary dementia. In this form of dementia we meet with the remains of the delusions of acute mania, and we also find an exaggerated state of emotional feeling which remains after the storms of acute mania have blown over, and the functions of the mind are beginning to suffer decay.

The diagnosis of general paralysis is very easy, after we have become acquainted with the disease.

In the early stage, the most marked symptom is a thickness of articulation particularly noticeable when the words articulated by the patient are composed of several consonants, when these will be shuffled over in a very characteristic manner. The lips of the patient while he is speaking will be seen to tremble, and likewise the tongue, if it is protruded from the mouth. The gait of these patients is very peculiar and characteristic of paresis. They shuffle along in a manner that denotes at once the want of co-ordination in the muscles of the limbs. Later in this form of insanity the power over the sphincters is lost, the patient has to be cared for like an infant, and becomes a great trouble to his attendants. There is another class of patients whose only manifestation of insanity consists in an abnormal condition of the moral power, and who exhibit no obvious intellectual aberration or impairment. The symptoms of the mental disease in these cases is limited to the exhibition of morbid impulses, which the intellect seems powerless to control. These cases of moral insanity are sometimes difficult to distinguish, and the laity generally attribute such manifestations to total depravity. In such cases, we must compare the patient with himself when in a state of health, and not with any imaginary standard of sanity or insanity. We should bear in mind in this class of cases the excellent definition of Dr. Combe, who says: "It is the prolonged departure, without any adequate external cause, from the state of feeling and modes of thinking usual to the individual when in health, that is the true feature of disorder of mind."

We have thus far considered the diagnosis of insanity only in its relation to the existence of the disease. Let us finally look at the diagnosis of recovery, which oftentimes becomes a very delicate and difficult task for the examiner. We are to determine whether the patient has recovered so far as to leave no trace of insane ideas and delusions. We must compare the man with his former self in a measure, and see if his natural tastes, affections, impulses and mental powers have been restored. Of course, we must make an allowance for a certain amount of weakness in his intellectual functions, just as we expect to find a man weak bodily, after an attack of typhoid fever or other severe disease. We must determine whether the man's intellectual faculties, his memory, reason and judgment, are in a state to enable him to take his place and position in active life. We must observe also whether his conduct is reasonable and quiet. In homicidal or suicidal cases we must assure ourselves of the disappearance of the propensity. There are many patients who, although not recovered, are in such possession of their intellectual faculties as to become very impatient of restraint and confinement, and no amount of reasoning can make them appreciate the necessity for further detention in an asylum. A marked case of this character is at the present time under our care, and illustrates forcibly this class of cases, who, were they to be exposed to the excitement of society, before a thorough cure has been effected, would almost inevitably have a relapse.

This patient will argue for an hour at a time very sensibly and forcibly upon the injustice and oppression of keeping him longer in an asylum, and will challenge any proof of his insanity, and probably nine out of ten physicians not acquainted with him would say the man was sane. He will converse rationally upon all topics of conversation until the subject of religion is introduced, when he immediately reveals gross delusions, and maintains with the utmost sincerity that he can perform miracles, and that he is frequently the subject of them. This shows the importance of ex-

aming a patient upon all conceivable topics before pronouncing him cured. These are the cases that generally make their friends and relatives, and particularly strangers, feel that they are unjustly detained, and are the ones who, if they obtain their release in any way, publish their wrongs, and create in this way ill-founded prejudices against institutions for the care of the insane. Generally speaking, if a person who has been insane expresses himself as having been unjustly treated and detained, and denies the fact of his insanity, we may be pretty sure that he has not fully recovered, as persons who are really convalescent are generally fully convinced that they have been insane and are generally very grateful for the care and attention that have been bestowed on them, and express themselves so. Such patients are nearly always willing to be guided by their physician's opinion as to the proper time for their discharge, and do not, as a rule, exhibit that intense restlessness and desire to return home, which is so apt to characterize doubtful recoveries.

AN EASILY EFFECTUAL METHOD OF ARTIFICIAL RESPIRATION.

By J. B. MATTISON, M.D.,

CHESTER, N. J.

AMONG the many exigencies arising in the accouchement-chamber, none, oftentimes, are fraught with more importance than those pertaining to the thorough establishment of respiration in the newly-born babe.

Momentous interests, affecting the worldly weal of many, may hang on the performance of this function, be the time of its complete carrying on never so limited; and, as well known, among the adherents of a certain ecclesiastical belief, the establishment thereof sufficiently long to permit a peculiar ritual performance, entitles the subject to a sharing in those joys that are to be.

Aside from these considerations the advent of the little stranger awakens emotions in the maternal bosom, such as only a parent can know, and to have fond hopes and loving anticipations dashed ruthlessly down, may give rise, in highly impressionable temperaments and under unusual circumstances, to symptomatic manifestations, seriously imperilling a life even more valuable. It behooves him, therefore, who takes upon himself the duties of the lying-in apartment to be fully alive to all its demands in this direction, and to meet promptly, with the most efficient means at his disposal, whatever of an emergency may arise. Every qualified practitioner is supposed to be cognizant of the various conditions standing in a causative relation to this state of apparent death, and their variety necessitates a varied plan of operative procedures looking to resuscitation. Often simple measures suffice, but, again, it is only after the most assiduous attention that we are rewarded by the first feeble evidences of an independent existence.

Among the different means of restoring asphyxiated infants, artificial respiration, after the manner of Hall or Sylvester, has long held a foremost place, and has been successfully resorted to after the failure of other measures. More recently another plan, that of Schultze, has come into notice; and as it may be unfamiliar to many practitioners, and is undoubtedly of value, the following description will, perhaps, be acceptable:

"The operator seizes the child under the arms, the index finger of each hand in the armpit, the thumbs over the anterior portion of the trunk, the remaining

fingers placed along the back, which is turned to the operator, while the head is steadied between the palms of the hands. As the operator stands, the child, so held, is allowed to swing between the outspread knees. The tractions thus made in both directions upon the ribs, by the pectoral muscles above and the abdominal muscles below, produce the widest separation of the ribs, while the weight of the liver causes descent of the diaphragm, and thus inspiration is produced. Next, with extended arms, the operator swings the child upward until the breech and legs fall forward toward the abdomen. When the body is thus doubled up, the ribs close together, the diaphragm is pushed upward and forcible expiration takes place, driving out through the mouth and nostrils great quantities of mucus and fluids—when respiratory movements have taken place prior to birth—from the air-passages. Still keeping the arms extended, the child should be allowed, after a few moments (?) to swing back between the legs. In this way expiration and inspiration are to be maintained until spontaneous respiration occurs. As the temperature is apt to fall during the swinging movements, warm water should be kept handy, in which to occasionally plunge the child."

We desire to call attention to another method, the value of which we have, on more than one occasion, demonstrated to our intense satisfaction, and which has, we think, advantages over that just detailed, in being more simple, seemingly not so rough and we judge equally efficacious.

We disclaim originality. Credit in that direction is due to Prof. Harvey L. Byrd, of Baltimore, who, in an article entitled "A 'Speedy Method' in Asphyxia," published in the *Baltimore Medical Journal*, November, 1870, and reprinted in the half yearly *Compendium of Medical Science*, January, 1871, described its *modus operandi*, and cited cases confirming its value.

The method we present has, however, some modifications of Dr. Byrd's, and is as follows:

The infant upon its back, firmly grasp the outer thigh, the index finger and thumb encircling, and the inner limb resting on the forearm, while the little finger is extended as far as possible up the back to form a fulcrum with the corresponding finger of the opposite hand. In the hollow formed by the thumb and forefinger of the right hand allow the neck of the infant to rest, with the palm under the shoulders and the little finger extending down the back to meet its fellow of the other hand. Now, gently and regularly depress the vertex and inferior extremities as much as practicable below the horizontal, say forty-five degrees, thus facilitating inspiration, and, after a proper interval, elevate them to the same extent, forming a concavity of the chest and thereby forming expiration. Continue these movements without interruption, taking care to permit no impediment to the exit and entrance of air during the upward and downward movements of the head and chest, and also exercising caution against too much lateral motion of the head during their continuance. The conjoined use of Desormeaux' douche, or a little cold water dashed occasionally on the epigastrium, will tend to enhance the efficacy of this method; indeed, its employment not at all precludes the use of whatever auxiliary measures may be deemed advisable.

In Prof. Byrd's plan the ulnar edges of the hands are placed in contact to form the fulcrum beneath the infant's back, the thumbs extended and the radial borders being alternately elevated and depressed. Simulate the normal respiratory act. Modified as above, its advantages are: a much firmer hold of the

body is obtained, thereby diminishing the chances of slipping; it is less fatiguing to the operator, and it obviates a necessity for an attendant to prevent any considerable departure of the head from its antero-posterior axis with the vertebral column.

We speak whereof we know regarding the efficacy of this method, having had ample evidence in that direction. Among other cases, notes of a remarkable instance of infantile asphyxia, in which it was, we confidently believe, the life-saving instrumentality, not only in establishing respiration after a notably protracted absence, but in maintaining existence through a perilously prolonged narcosis, go far in substantiating the statement of its originator, that "it is, *par excellence*, the remedy in the asphyxia of newly-born infants."

We have met those of large experience who were unacquainted with it. In the hope that it may be given a wide publicity, and its merits made available, we represent and commend it to the profession.

Progress of Medical Science.

SEEGEN ON DIABETES MELLITUS.—The following is a summary of Seegen's views which have appeared in the form of a notice of his recent work in the *Berliner Klinische Wochenschrift* for April 26th, 1875:—With our present chemical and physical resources we cannot determine the existence of sugar in healthy human urine, and we must therefore express the opinion that such urine does not contain sugar. Consequently any excretion of sugar in the urine which is not merely momentary and due to transient causes is pathological. A distinction between diabetes mellitus as a disease, and mellituria as a harmless exaggeration of a physiological process, is not justifiable; even the most moderate excretion of sugar, if it be continuous, may occasion all the symptoms belonging to diabetes mellitus. The excretion of sugar is the result of an anomalous conversion of the glycogen of the liver into sugar. There is no direct excretion of the sugar taken with the food. There are two forms of diabetes dependent on the source of the glycogen, viz.: first, when only the glycogen formed from the hydrocarbons is converted into sugar; and, second, when the glycogen which arises from the splitting up of albuminates is so converted. In the first form, therefore, there will be an excretion of sugar only when hydrocarbons are introduced into the system, while in the second it may take place even with an exclusively animal diet. The explanation of this anomalous conversion is generally referable to pathological changes and lesions in the region of the central nervous system, whatever may be the immediate cause of the sugar-formation. There is a peculiar connection between an excessive formation of fat, and the excretion of sugar; so that, especially in young persons, the formation of fat is sometimes observed as an early stage in severe cases of diabetes. The symptoms of diabetes may be divided into two groups, viz.: first, those due to the presence of sugar in the blood and fluids of the various tissues; and, second, those caused by defective nutrition resulting from the anomalous conversion of matter. The degeneration of the tissues is never the cause, but rather the result, of diabetes mellitus. An inherited tendency to the disease is not infrequently proved. That form of the disease is the milder where the sugar is secreted only after the ingestion of hydrocarbons. Its course is most favorable when there remains a degree of tolerance of amylace-

ous articles, while that form reaches a fatal termination much more rapidly in which sugar is formed on a diet of albuminates. He has never observed a cure of diabetes in the sense that amylaceous articles could be eaten in great abundance without occasioning the excretion of sugar. The prognosis depends first upon the form of the disease; second, upon the age of the patient; third, upon the ability to partake freely of animal food; and fourth, upon the temperament. In the treatment the regulation of the diet is the first and most important factor. Alkalies and alkaline mineral waters have hitherto proved to be the best remedies. The use of the Carlsbad water always has a favorable effect upon the symptoms. While it may not check the excretion of sugar, its favorable action in the milder forms is by increasing the tolerance of the hydrocarbons. Of all known remedies, opium and its preparations have the most decided influence on the excretion of sugar, even in very severe cases. The effect, however, is only exceptionally lasting.

DILATATION OF THE OESOPHAGUS.—Mr. Henry Davy reports the following case of this rare disease. A gentleman living in the country, while lifting a heavy weight, gave himself a severe strain, and felt, he said, that something gave way inside of his body, and from that time until September, 1869, he then being thirty-eight years of age, the following symptoms were developed. He stated that for the past ten years he had experienced difficulty in swallowing, nausea and vomiting very soon after taking food, and especially after breakfast. At times he would feel better than at others. For years he had not been able to sleep on the left side, and when he did attempt it, he felt a smothering sensation, which was followed by the vomiting of large quantities of a slimy fluid, which was free from acidity and without a disagreeable taste. He had lost much flesh during this period.

Mr. Davy, on examination, found him complaining, on attempting to swallow, of a raking or tearing sensation, which was referred to the epigastrium. He also had a sensation of heat and burning extending over the course of the oesophagus, and he experienced an obstruction to the passage of food into the stomach about the ensiform cartilage, to the right side. The vomited matters consisted of glairy mucus. The sickness was in a great measure relieved by lying on his right side; his appetite was craving, and he suffered much from thirst. A pulsation could be felt over the epigastrium, like that caused by an aneurism. There was considerable pain on pressure and dulness on percussion in this situation. There were no other indications to indicate malignant disease. He was ordered the usual remedies to relieve the sickness, together with a fluid diet, but without effect. As the patient seemed to be sinking, nutrient enemata were then used, with very small quantities of liquid food by the mouth, but the latter were invariably rejected. This treatment was continued for a month, when he experienced a sensation in his stomach as if something had opened or given way, and felt the food pass down, which was followed by a copious discharge of fecal matter from the bowels. After this he could retain the food in his stomach, and in a short time became quite convalescent.

For the next five years the patient was in apparently good health, and the only inconvenience he experienced was being obliged to take his meals in a semi-recumbent position, with his right arm over the back of a chair, having found this the only posture that would allow the passage of food into his stomach. In January, 1875, he had an attack similar to that de-

scribed above, no food remaining on his stomach, and he died from inanition, after an illness of some ten days.

At the post-mortem examination, the œsophagus was found greatly dilated throughout its entire course, and measuring at the upper part of its lower third nine inches, and through the rest of its circumference above and below about eight inches. The muscular coat was very much hypertrophied. It contained about a wineglassful of fluid, which was prevented from entering the stomach by a twist at the cardiac extremity, at its passage through the diaphragm. Mr. Day considers that this would account for the ease in swallowing when the patient stretched himself. The œsophagus was found to have a capacity of two pints, and its mucous membrane was found studded with several small ulcers.

The stomach was also found to be dilated, with a capacity of nine and a half pints. No evidence of any malignant disease could be found, and nothing to account for the pulsation felt during life over the epigastrium.—*Irish Hospital Gazette*, May 1, 1875.

MEMBRANOUS EXUDATION IN THE THROAT FOLLOWING A SCALD.—At a recent meeting of the Clinical Society of London, Mr. R. W. Parker gave the history of a child, three years of age, that had put its mouth to the spout of a kettle, which was boiling on the hob, and from which steam was actually issuing at the time.

That same evening she could not swallow, though there was no difficulty in her breathing. There was no change in her respiration until the end of three days after the occurrence, when it became labored, and a croupy cough was noticed for the first time. On the sixth day she was admitted to the Hospital for Sick Children, when she was found to be in a very low condition, her voice gone and her respiration very rapid. The mouth was examined, and all that could be discovered was a small patch of membrane on the posterior wall of the pharynx. An ice-bag was applied to the neck, but as there was no amelioration in the symptoms at the end of a couple of hours, tracheotomy was performed. Two long pieces of membrane were removed by means of a feather, one of them tubular, and about the size of a crow-quill. She was greatly relieved by the operation, but her general condition rapidly became worse, and she died thirty-six hours later of blood-poisoning and exhaustion.

At the post-mortem examination two small erosions were found on the hard palate, at its junction with the soft. The anterior surface of the soft palate was normal; its posterior surface was rather swollen and mammilated in appearance, from swelling of the glands of its mucous membrane. A small patch of membrane was found on the base of the uvula, one just above the left arch of the palate, and another on the posterior surface of the pillars of the fauces; these pieces were not perfectly separable from the mucous membrane. The epiglottis was covered with membrane, and was thickened and swollen, as were also the aryteno-epiglottic folds. The tracheal mucous membrane was red and injected, and coarsely granular in appearance; and this appearance extended as far as the tertiary bronchi. In some of the bronchi, pieces of thin, reddish, well-formed membrane were found. The lips, tongue, and tonsils were normal.

An interesting discussion followed as to whether the membranes in this case were the result of the inhalation of the steam, or were of a diphtheritic nature. Mr. Parker believed that they were diphtheritic, and claimed that the post-mortem evidences sustained his view. Dr. Dickinson narrated instances in which membranous exudations in the air-passages

could be directly traced to scalds, wounds, and mechanical irritants.—*British Medical Journal*, May 1st, 1875.

AIDS TO DIAGNOSIS IN SYPHILITIC NERVOUS DISEASE.—Dr. Dreschfeld calls attention to the following points, which will aid the practitioner in determining whether a nervous disease is of syphilitic origin. They are as follows:

1. Age of patient. The age of persons affected with syphilitic nervous disease ranges between 25 and 40: out of ninety-six collected by Brans, sixty were of patients between 20 and 40 years old; the cases given by Broadbent, Buzzard, and others, exhibit the same proportions.

2. A syphilitic history. This, he says, is often difficult to obtain, especially in women; often when the syphilitic virus selects for its locality the nervous system, there are few, if any, secondary symptoms; while, on the other hand, nervous troubles coming on in a syphilitic patient may be simply due to a coincidence. In many recorded cases, certain forms of syphilitic nervous disease are much more often preceded by well-marked secondary symptoms than others; this being true, he says, of syphilitic epilepsy and the more acute cases of meningitis, which come on soon after infection.

3. Multiplicity of lesion. Nervous symptoms which can only be accounted for by the assumption of separate pathological products situated in different parts of the nervous system, are almost always due to syphilis.

4. Absence of other causes. This applies particularly to the paralysis of the different cranial nerves, and to sudden attacks of hemiplegia in young persons, in the absence of any cardiac or renal troubles.

5. Influence of anti-syphilitic treatment. In many cases, where the course of the nervous disease is acute, and where the patient has not previously undergone an anti-syphilitic treatment, the effects of the iodide and the mercury are very marked. In the more chronic cases, however, where the syphilitic deposit has itself undergone degenerative changes, and has established secondary changes in the surrounding nerve-matter, the treatment will, of necessity, be of little avail.—*The Practitioner*, May, 1875.

ADMINISTRATION OF CHLORAL AND BROMIDE OF POTASSIUM BY THE RECTUM.—Mr. Griffith, of London, has published his notes of a case of acute puerperal mania, in which the patient became so violent on any attempt being made to give her food, draw off the urine, etc., that he was obliged to administer chloroform in all such cases. Food had to be administered by the rectum on account of the irritability of the stomach. Chloral \mathfrak{ss} . and bromide of potassium \mathfrak{ij} . mixed with an egg, milk, and brandy injection which she had previously been taking, produced good results in allaying the mania. Mr. Griffith thinks that in many cases this method of administering these drugs will be found useful, as there is less liability to vomiting than in giving them by the mouth, and in this case no diarrhœa or other irritant effect was produced on the bowel. He also reports the case of a lady suffering from the passage of gall-stones, in whom the inhalation of chloroform and hypodermic injections of morphia and other remedies had failed to secure rest and sleep, while they were obtained in a short time by the injection per rectum of half a drachm of chloral.

He has also used the drug in this way in cases of menstrual pain and sickness, in uterine and ovarian irritation attended with pain, and also in some rectal diseases.—*British Medical Journal*, May 8th, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, June 12, 1875.

THE PRESBYTERIAN HOSPITAL AFFAIR.

THE longer the managers of the Presbyterian Hospital delay an answer to the protest of the sixty physicians, the more difficult appears to be the task. The request to show some cause for the virtual dismissal of four members of the medical staff was on its face so reasonable, and appealed so directly to a sense of fair dealing, that the failure of the managers to comply is the most extraordinary feature of the whole proceeding.

We cannot believe that these managers would be guilty of any act of which they would be ashamed, or that they would have made any such radical change in the Medical Board without due consideration and without good reason, and yet what are we to think of their persistent silence when asked to assign a cause for their action by gentlemen who believe themselves injured thereby? The very failure to answer gives a color to the suspicion that the cause is not such a good one as they might wish it to be. The managers have the absolute power of appointing the staff, and in accordance with the rules and regulations of the hospitals, of changing it every year by a formal election. No one can question their right to do so, but there is some middle ground upon which the managers and medical board should meet, where there should be an honorable understanding of mutual dependence and a manly consideration of the rights of each. The managers having all the power, can at least afford to be magnanimous.

How much better it would have been if this board had stated to the gentlemen who were not likely to be re-elected, the charges that had been brought against them, and extend to them the ordinary courtesy of an invitation to resign. This was a little matter of form, for the neglect of which the managers have merited the censure of the profession, and given the management of the hospital a far from enviable notoriety.

The deposed gentlemen may or may not have merited the punishment which they have received, but this is not the question at issue. The profession merely view these gentlemen in the light of exponents of a principle, the vindication of which is dear to every one who holds a hospital appointment, or expects to be a candidate for such a distinction. It is the question of right which any managing board has of ignoring past services of a medical staff, of publicly severing their connection with a hospital without the acknowledgment of any obligation to state the reason therefor. The profession has a right to feel a deep interest in this matter, as it involves the surrender of reputation, respectability, and individual rights, into the keeping of men who are not willing to acknowledge their worth, even if they may admit of their existence.

If the managers are satisfied that they acted for the best interests of the hospital, it is right, in their own behalf, and in behalf of the institution, to say so; if, on the contrary, they have done an injustice to their medical staff, it is also right that they should say so; but by a persistent silence both parties are injured. The trustee party, however, must suffer the most. It is in the power of the trustees to answer a very reasonable request, and a persistent determination not to do so forces even an impartial observer to the conclusion that their motives may not be above question, nor their appreciation of justice above that of ordinary men.

It is useless to assert that this is a matter which does not concern the profession. In this the managers are very much in error, as the protest of the sixty representative physicians very clearly proves. Professional sentiment is not narrowed to those signing that paper, but is extending itself into all the associations represented by each of these gentlemen, and the board of management of this or of any other hospital may yet learn to its sorrow that it is not so dignified that it cannot afford to be courteous, so influential that it cannot be reasonable, so powerful that it need not be just.

That the protest of the sixty outsiders is not a blind endorsement of the four gentlemen who have been displaced, is evident from the fact that the majority of the old medical board of the hospital have signed protests of similar import, and presented them to the managers. This being the case, if the managers persist in refusing to consider the protests in question, there is, it seems to us, but one of two courses for the staff of the hospital to pursue—either to resign, or to give some good reason why they remain. From what we know of the gentlemen who took the four places, we are free to say that they must have satisfied themselves that it was right and proper so to do; but they also, under the circumstances, owe it to their brethren either to state the reasons for their acceptance of the positions, or to resign. Altogether, the present medical staff has been forced into a very undesirable position—one which involves a good deal of responsibility to the profession. It is nothing more nor less

than the vindication of a principle, and their brethren are anxious to know if they are equal to the occasion. The next meeting of the board of managers will determine whether any answer will be made to the protests, and if none is offered, the time will have arrived either for a general explanation from the staff, or a general resignation.

Reports of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

First Session, held at New York City, June 2, 3, and 4.

WEDNESDAY, JUNE 2D—FIRST DAY.

THE Association was called to order by DR. E. C. SEGUIN, Secretary of the Committee on Organization, and upon motion, Dr. J. S. Jewell, of Chicago, was elected temporary chairman.

The roll of members contains the following names:—Drs. J. S. Jewell, Walter Hay, and H. M. Bannister, of Chicago; Dr. R. Bartholow, of Cincinnati; Dr. J. K. Bauduy, St. Louis; Dr. M. Burnett, of Knoxville; Dr. E. R. Hun, Jr., of Albany; Drs. E. H. Clarke, R. T. Edes, J. J. Putnam, S. G. Webber, and F. D. Lincoln, of Boston; Drs. S. Weir Mitchell, Wm. Pepper, and H. C. Wood, Jr., of Philadelphia; Drs. J. Van Bibber and F. T. Miles, of Baltimore; Dr. H. D. Schmidt, of New Orleans; Dr. F. D. Lente, of Cold Spring, N. Y.; Dr. J. C. Shaw, of Brooklyn; Drs. W. A. Hammond, Meredith Clymer, E. C. Seguin, T. B. M. Cross, J. J. Mason, F. K. Kinnicutt, A. D. Rockwell, D. B. St. John Roosa, A. McLane Hamilton, E. G. Loring, J. C. Dalton, J. W. S. Arnold, N. B. Emerson, T. A. McBride, and J. S. Lombard, of New York.

After the calling of the roll, Dr. T. A. McBride, of New York, offered the following resolution:

"It being the sense of this Association that its proceedings should be reserved for the profession and the medical press, be it

Resolved, That reporters from non-medical journals be excluded from the meetings of the Association; and that any information requested by the press be furnished by the Secretary under the guidance of the officers of the Association." Adopted.

CONSTITUTION AND BY-LAWS.

DR. CLYMER, of New York, from the Committee upon Organization, submitted the following Constitution and By-Laws for the consideration of the Association:

I. This Association shall be named and known as "The American Neurological Association."

II. It is established to promote the study of Neurological Science in all its departments.

III. There shall be two sorts of members, namely, active members—not exceeding at any one time fifty in number, and who shall be at the time of their election residents of the United States—and foreign associate members, not exceeding at any one time twenty-five in number, and who shall be non-residents. Active and foreign associate members shall be elected by ballot on the recommendation of the Council, on one day's previous notice of such ballot, by a majority of all the members present.

Provided, that no one shall be eligible for active membership unless he has previously submitted a paper on some subject connected with neurological

science, which paper shall be referred to the Council for examination and report. Active members only shall be entitled to vote at any meeting, or be eligible to any office.

IV. The officers of the Association shall be a President, two Vice-Presidents, a Corresponding Secretary, a Recording Secretary, who shall perform the duties of Treasurer, and a Curator. They shall be nominated by a Committee of Nominations of five members, appointed by the President on the first day of the annual session, and who shall report on the day following, immediately after which the election shall take place. The election shall be by ballot, and the person who shall have the greatest number of votes shall be declared elected to the office for which he may be a candidate.

In case of a vacancy occurring in any office between the dates of the annual election, it shall be filled by the Council until the next annual election.

The officers shall enter upon their duties immediately after the organization of the annual session next after their election, and shall hold office for one year.

Provided, that the officers of the first session shall be elected immediately after the organization of the Association, and shall hold their offices until the election at the second annual session.

V. The Council shall consist of the officers of the Association, shall manage the affairs of the Association, subject to the Constitution and By-laws, and shall report to the Association at large at each annual session.

VI. The annual session of the Association shall be held on the first Monday in June in each year, and at such place as shall be designated by the Association at the previous annual session, and shall continue for three days, unless the time be extended by a vote of the Association.

VII. This Constitution may be amended by a two-thirds vote of all the members present, at any annual session, provided that notice of said proposed amendment in writing be given at the annual session immediately preceding.

BY-LAWS.

1. Each and every member of the Association shall pay annually to the Recording Secretary the sum of five dollars.

No member who shall be in arrears for one year shall be entitled to vote, or be eligible to any office in the Association.

2. The officers of the Association shall discharge the duties belonging to their respective offices. The President shall be ex-officio chairman of the Council.

3. The Council shall meet as often as the business of the Association may require. They shall keep a record of their proceedings, which shall be read at the annual session of the Association. They shall not have power to make the Association liable for any debts exceeding in total the sum of one hundred dollars in the course of any one year, unless specially authorized to do so by a recorded vote of the Association.

4. The order of business at each meeting of the Association shall be as follows:

5. The titles of all papers to be read at any annual session shall be forwarded to the Corresponding Secretary not later than one month before the first day of the session. All papers that may be read before the Association and accepted shall become the property of the Association, and their publication shall be under the control of the Council. All publication of the meetings of the Association shall be under the direction of the Council.

6. These By-Laws, or any one or more of them, may be amended, or repealed, or suspended by a two-thirds vote of all the members present at any meeting during an annual session, provided notice in writing of any proposed amendment or repeal has been given at the meeting immediately preceding the one at which the motion is made and the vote taken.

The Constitution and By-laws as reported were adopted.

The CHAIRMAN appointed as Committee on Nominations: Drs. Putnam, of Boston; Lente, of Cold Spring; Hum, of Albany; Seguin, of New York; and Hay, of Chicago.

A recess of fifteen minutes was taken, and when the Association was called to order, the committee made the following report:

ELECTION OF OFFICERS.

For President: Dr. S. Weir Mitchell, of Philadelphia.

For Vice-Presidents: Dr. J. S. Jewell, of Chicago; Dr. E. H. Clarke, of Boston.

For Corresponding Secretary: Dr. J. J. Mason, of New York.

For Curator: Dr. J. W. S. Arnold, of New York.

For Recording Secretary and Treasurer: Dr. E. C. Seguin, of New York.

Upon motion of DR. HAMMOND, the Secretary was instructed to cast the vote of the Association in the affirmative for candidates nominated by the committee.

In the absence of the President the first Vice-President, DR. JEWELL, called the Association to order, thanking the members for the honor they had conferred upon him, and expressed the desire that nothing should be done, or fail to be done, which would prevent the present session from becoming pleasant and successful. For the future of the Association he could see no reason why annual sessions could not be held, at which papers of real interest should be brought forth, full of usefulness in every way; stimulating the labors of those, both in this country and abroad, who are working in this special department of medical science. It was his hope that the Association, as a whole, would work earnestly for the advancement of everything which pertains to neurological science in its highest aspect.

Upon motion, the Association at once proceeded to the reading of papers.

The first paper of the session was read by Dr. WEBBER, of Boston, and entitled

CONTRIBUTIONS TO THE STUDY OF MYELITIS.

The paper consisted essentially in the report of two cases, with autopsies and a description of the changes which had taken place in the tissues of the spinal cord, as observed under the microscope. They were regarded as cases—especially the first—which would contribute to prove that other parts than the anterior ganglion-cells are affected, either primarily or secondarily in a certain class of cases. From the clinical history, these cases were regarded as belonging properly under the class cited by Dr. E. C. Seguin, in a paper read before the New York Academy of Medicine, in November, 1874, under the head of "Acute and Sub-acute Spinal Paralysis, or Inflammation of the Kinesodic Tract of the Spinal Cord." They were not, however, looked upon as due primarily to lesion of the anterior cornua exclusively, and atrophy of the nerve-cells there situated; but the writer was inclined to believe that the first stage is one of congestion. The changes found were regarded as due

to inflammation and destruction of the nervous elements of the spinal cord, fibres, and ganglion-cells. In the muscles all forms of changes were observed except the amyloid.

Discussion postponed until Thursday.

Upon motion of DR. LENTE, a Business Committee, consisting of the Secretary and two others, was appointed to arrange for the time of reading papers. Drs. Mason, of New York, and Hay, of Chicago, were appointed.

The Association then adjourned to meet at 2 P.M. June 3d.

THURSDAY, JUNE 3D—SECOND DAY.

The Association was called to order by Vice-President Jewell, and the minutes of the previous meeting read and approved.

DISCUSSION ON MYELITIS.

The first order of business being the discussion upon the paper read by Dr. Webber at the first session,

DR. PUTNAM, of Boston, remarked that he knew of no absolute sign which indicated the presence of congestion of the spinal cord, and inquired of Dr. Webber by what signs he would recognize that condition, and also whether congestion can exist to any extent in the spinal cord without being accompanied by nutritive changes? In other words, can we by any signs tell where congestion ceases, and actual change in structure begins?

DR. WEBBER, of Boston, replied that he supposed it would be exceedingly difficult to determine exactly where congestion ceases and inflammation begins. The physiological action of the spinal cord is such that its functions are more easily deranged by slight influences, as a deficient or increased supply of blood, than some other organs, but knew of no means to decide whether mere congestion or organic change is present at any given time. If the patient has symptoms referable to one or other condition, and recovers entirely, no symptoms remaining, we are perhaps justified in assuming that it was congestion that gave rise to these symptoms; but if any disturbance of function continues permanent, it is probable that the change which took place was organic.

DR. PUTNAM inquired still further whether the blood can be increased in the spinal cord without such increase being preceded by some influence upon the cord? He was not aware of any absolute proof of this, although he has no doubt that the blood of the spinal cord varies in amount, and varies according to the influences acting upon the vaso-motor system.

DR. HAMMOND, of New York, remarked that we have some proof in the way of analogy. It is a well-known fact that emotions influence the amount of blood over the face and chest, and what emotion can do to the face and chest it may do to the spinal cord. There is no difficulty in adopting the view that the brain and spinal cord may be subject to local congestion, but the actual proof is a far different question.

DR. MILES, of Baltimore, remarked that from the experiments of Van der Kolk it was quite probable a certain degree of hyperemia was necessary to the proper performance of function, and that activity of function might accordingly indicate perhaps to some extent the amount of hyperemia present; but he was of the opinion that it is not possible to draw a line of distinction to an extent which will enable us to determine where congestion ends and inflammation begins.

DR. E. C. SEGUIN, of New York, remarked that the two important points in the paper of Dr. Webber

were, *first*, the pathological anatomy and possible connection between the symptoms and the lesions. For it is by such study that we are enabled to connect certain symptoms with certain morbid changes. In the second place, he regarded the two cases cited as radically different in nature. The second was one of localized myelitis involving every part of the cord. The first case had some very peculiar features, such as the wasting of the muscles and the absence of alteration in the nutrition of the skin, especially upon the buttocks, and he regarded it as a case of spinal paralysis of the adult. The diffuse myelitis in the white and gray matter of the cord he regarded as a valuable point in the pathological anatomy of the case.

Dr. CLYMER, of New York, related a case of acute spinal paralysis, with the view of drawing special attention to the treatment adopted. The patient suffered at first from general malaise, with marked feebleness of the lower extremities, and slight feebleness of the left arm, and after five or six days he was completely unable to get out of bed. His tongue was coated and dry, skin dry, pulse 90, numbness and tingling of the extremities, etc. At first sight the case appeared like one of typhoid fever, but it lacked the peculiar physiognomy, the eruption, gurgling in the right iliac fossa, etc. The patient had been training himself for a foot-race, and had received a sudden check of perspiration.

Regarding it as a case of spinal congestion, he was cupped largely and freely over the cervical and lumbar vertebrae. On the following day the cupping was repeated, and followed by free blistering. The result was that the acute symptoms disappeared, all fears of fever were dispelled, but the paralysis remained in the lower extremities. The cupping was occasionally repeated with some counter-irritation, and after some weeks the down current was applied through the cord to the lower extremities, and the patient rapidly improved in his ability to walk. The atrophy of the glutei muscles, and the muscles of the left arm and the deltoid, was very decided. The patient is now able to walk without much imperfection in his gait. He was of the opinion that the case was one of congestion of the spinal cord, accompanied by some destruction of the cells in the anterior cornua, and believed that it would have gone on to the production of more serious changes, had not the treatment been actively antiphlogistic.

The second order of business was the report of a case of

SPINAL PARALYSIS WITH PARTIAL RECOVERY—BY DR. MILES, OF BALTIMORE.

The patient had been under the influence of excessive venereal excitement, had taken a sudden cold, and almost immediately found his left side partially paralyzed. In this condition, but with great difficulty, he came to Baltimore, and the day following his arrival the other side became partially paralyzed. The third day he was absolutely paralyzed, except the muscles of the face and the muscles of deglutition. He was a living face with a body absolutely dead to all appearance. He suffered no inconvenience or pain. Sensibility remained perfect, and the sphincters were sound. The muscles responded to mechanical irritation as readily as normal. He remained in this condition for three or four days, when slight motion was noticed in the fingers, which gradually increased, and the movements of the arms were soon restored, and power gradually returned to all the muscles.

The treatment consisted in the use of cups along the back, iodide of potassium, bichloride of mercury, and

the faradic current. No single muscle was left paralyzed.

When seen lately there was noticed to be a slight imperfection in walking, but he can walk without a cane or crutch. The interossei muscles of the hands and feet showed atrophy. The case illustrates how perfect paralysis of this sort may be and every muscle recover from its paralyzed condition. In the present case it is probable that the congestion has left its mark, and perhaps in certain places in the cord minute lesions of a hemorrhagic character have been produced.

Dr. HAMMOND asked whether reflex excitability was present or not.

Dr. MILES replied that there was none.

Dr. HAMMOND remarked that he believed all would agree that such cases of paralysis generally recover under appropriate treatment. The more sudden and intense the paralysis is in a case of that nature, the more apt it is to get well.

He then related a case where the patient fell perfectly paralyzed in every limb, and in that condition was brought to the city. When first seen, he also had facial paralysis. There was no evidence of syphilis. He was treated with large doses of iodide of potassium, bichloride of mercury, the galvanic current, where it would act, and the fluid extract of ergot. The patient recovered completely, and was as well as any one. He regarded the case as one of congestion, with very great effusion, and that with the absorption of the effused fluid the congested condition of the vessels disappeared, and the recovery naturally followed.

In Dr. Miles' case there seems to have been some more permanent lesion, but in my case the muscles are perfect, and the patient moved about perfectly well within six weeks after the attack.

ATHETOSIS.

Dr. HAMMOND, of New York, presented a case of this kind occurring in a man who has been the subject of epileptic paroxysms and a hard drinker. It was the original case upon which was based the description he had given of the disease.

The motions of the fingers *continue through the night*, and in this respect the description given must be modified.

Dr. CLYMER mentioned a case seen more than thirty years ago, but at that time it was supposed to be choreaic in nature.

Dr. JEWELL referred to a case accidentally seen, occurring in a girl who was epileptic. These movements had been going on for two or three years in the right hand, and were then slightly apparent in the left hand.

Dr. HAY referred to a case accidentally seen, of which he hoped to be able to obtain a history.

Dr. CROSS, of New York, referred to two cases of the disease where the movements were upon the left side and were not preceded by epilepsy. In one case the patient was a female, and the movements were in the feet as well as in the hand.

Dr. E. C. SEGUN reported a case occurring in a female 22 years of age, where the condition had been developed after infantile hemiplegia.

He also mentioned the fact that he had noticed in two cases what he had termed the athetosis-like state. In these cases, both boys, one about four and the other seven or eight years of age, there was hemiplegia of cerebral origin, and there was present a certain degree of secondary contraction in the paralyzed parts. They were unable to bend the contracted fingers when asked to do so, but there was an involuntary spasmodic action by means of which the fingers were opened, and opened beyond the normal extension.

In the case of the girl there was hypertrophy of the muscles.

DR. WEBBER inquired whether the child opened the non-paralyzed hand at the same time the paralyzed one was opened.

DR. SEGUIN replied that in one patient there was no such sympathetic movement in the opposite hand.

DR. VAN BIBBER reported a case of right hemiplegia in a patient five years of age, in which complete recovery did not occur. There was present some secondary contraction, and also the condition referred to by Dr. Seguin. The muscles were hypertrophied in a remarkable manner.

TREATMENT OF PARALYZED MUSCLES BY ELASTIC RELAXATION.

DR. VAN BIBBER, of Baltimore, read a paper upon the above subject, in which he set forth the physiological conditions which underlie the advantages claimed for this method of treating paralyzed muscles. The views of the writer can be found in the May number of the *New York Medical Journal* for 1873, together with cases.

DRS. SEGUIN and HAMMOND bore testimony to the efficacy of this plan of treating paralyzed muscles, and regarded it as of special benefit in the treatment of facial paralysis and paralysis from lead poisoning.

DR. N. B. EMERSON, of New York, referred to the relation existing between electro-muscular contractility and tension as a possible explanation of the benefit derived from this plan of treatment. When the origin and insertion of a muscle are approximated, a much less amount of electric influence is required to cause muscular contraction.

DR. SEGUIN regarded this as a point of considerable practical importance, and reported a case in which no response could be obtained to the galvanic current from the muscles in the anterior tibial region, and it was suspected that the stretched condition of the muscles resulting from a double talipes equinus was the reason why no response could be obtained. Tenotomy was performed, and on the fourth day after the operation, the muscles having been relaxed, there were distinct muscular contractions in response to the galvanic current, which continued to improve. The operation was done in 1871.

INJURY OF THE BRACHIAL PLEXUS.

DR. PUTNAM, of Boston, reported a case in which the arm had been forced into extreme extension by the premature discharge of a cannon. The arm was severely burned, but there was neither fracture nor dislocation. Complete discoloration of the skin took place, and the limb became blue. Almost complete recovery has now taken place, as far as the ulnar nerves are concerned, and as far as sensation goes in the parts supplied by musculo-spiral. The only parts now remaining cyanotic, are those supplied by the median nerve. It was interesting to notice that when the cyanotic parts were rubbed very lightly that the discoloration would disappear and the skin remain of its natural color for some time, showing that some influence was exerted upon the vaso-motor nerves by the manipulation, and is probably due to reflex action through the median nerve. The disappearance of discoloration would seem to indicate dilatation rather than contraction of the vaso-motor nerves. The principal point of interest was the extent of the injury done to the brachial plexus by forcible extension of the arm. Galvanic current is the only treatment resorted to.

DR. HAY, of Chicago, referred to a case of injury to

the brachial plexus without dislocation or fracture. The lady fell from a balcony, striking upon her extended left hand and arm; there was some numbness and dull pain about the arm, which was so aggravated, after about forty-eight hours, that a surgeon was called, upon the supposition that some dislocation or injury of surgical character had been sustained which had been unrecognized. At the end of eight weeks the arm was entirely motionless, fingers extended and paralyzed and in close apposition with each other, and the patient suffered severe pain between the shoulders, in the neck, arm, forearm, and down the fingers. After eleven weeks had elapsed considerable atrophy of muscles was manifest, and the forearm had diminished in size one-third; interossei muscles disappeared rapidly; skin became white and glistening.

Notwithstanding the severe pain upon motion, there was anesthesia. The treatment consisted of blisters along the course of the cervical and brachial plexuses, with strychnia and cod-liver oil, etc. An almost complete recovery took place.

DR. JEWELL referred to the reflex vaso-motor action as an interesting point in Dr. Putnam's case, and regarded the case as one of an instructive class, illustrating the ease with which a sensation can be introduced into a nerve-trunk and conveyed if you please to the vaso-motor centre, and from that an answer sent out.

DR. E. C. SEGUIN, of New York, reported additional cases of injury of brachial plexus, and drew special attention to a point in diagnosis, the observance of a symptom which has escaped observation entirely in this country, and has been mentioned by only one or two observers abroad. He had based this symptom upon observations made in two cases. The symptom which attracted attention was contraction of the pupil upon the same side of the injury to the brachial plexus. In both cases, the pupil in a moderate light did not dilate to the full extent, and resembled the pupil of the general paralysis of the insane, or of locomotor ataxia at certain stages. It was a fixed and moderately contracted pupil. This paralysis represents in a moderate degree the paralysis of the sympathetic nervous system, and was probably produced in the cilio-spinal centre and its ramifications upward. The exact mechanism of this pupillary contraction is obscure, but he was inclined to the opinion that it could be most satisfactorily explained upon the inhibitory principle.

This symptom may be of possible service in making out obscure cases of injury about the shoulder. It would be interesting also to determine the exact point in the brachial plexus, an injury of which will produce this distant vaso-motor paralysis.

DR. HAMMOND inquired whether contraction had been noticed accompanying paralysis induced by pressure upon the brachial plexus. He related one case where paralysis was produced in that manner, and the pupil upon the affected side was permanently contracted either in the light or dark. Motion in the arm was almost entirely destroyed and sensibility to a great extent. He regarded the case as interesting from the fact that probably there was no tearing of the structures, but the effects were due alone to pressure.

DR. SEGUIN remarked that the case just related goes to strengthen the proposition that contraction of the pupil is evidence of actual gross injury. He was of the opinion that the pressure produced by the back of the chair caused a separation of the myelin; there may have been severance of the axis cylinders. The non-recovery of the patient shows that there must have been secondary degeneration beyond the point of severance. The physiological separation in such cases is

the same, whether produced by pressure, or by laceration, or by the knife.

Dr. McBRIDE referred to a case similar to that mentioned by Dr. Hay, in which there was no pupillary contraction present. He also referred to a case where a large tumor was present upon the side of the chest, and contraction of pupil was noticed; and another case of old dislocation of the shoulder accompanied by small pupil upon the same side.

Dr. KINNCUTT recalled a case in which the symptoms indicated severe injury to the brachial plexus, and yet there was no pupillary contraction present.

Dr. PUTNAM referred to the fact that inequalities of the pupil had been noticed in connection with various diseases of the chest.

Dr. JEWELL mentioned a case where not only contraction of the pupil was present upon the same side of the injury, pressure from a crutch, but there was also flushing of the same side of the face, and the temperature was also elevated upon that side. Another case was alluded to in which there was inflammation of the upper lobe of the right lung, accompanied by a similar phenomenon, and there was also left a marked degree of tenderness over the inferior cervical ganglia, and pressure upon this ganglia produced immediate sweating upon the right side of the face, the pupil contracted, and the patient at once experienced vertigo. These symptoms gradually disappeared.

Dr. HAMMOND remarked that he had long since come to regard inequalities of the pupil as of no special significance, unless accompanied by other symptoms, and referred to a case in which contraction of the pupil was produced by a seton in the neck, and kept up as long as the seton remained.

NERVE INJURY—CUTANEOUS ERUPTION.

Dr. VAN BIBBER reported a somewhat remarkable case, in which a needle had been thrust into the arm of a woman, where it remained two months, and then was extracted, without giving any special amount of pain. The next day a crop of bullæ appeared upon the arm, which was followed by successive crops of like character, accompanied with great pain, and the pain preceded the appearance of the eruption. These eruptions continued until the arm, from the insertion of the deltoid down to the wrist, became one continuous sore. When the bullæ broke or were opened they left behind open ulcers that showed no tendency to heal, and were more or less covered with hemorrhagic spots. There was anesthesia over the entire region of the median nerve, and marked paralysis associated with lesions affecting the wrist and elbow joints.

Under the use of the constant current the bullæ at once began to disappear, and showed no tendency to return, and within three weeks the arm was free from the eruption. When the pain recurs the galvanic current stops it at once. Since the improvement scattered bullæ have appeared upon the face and about the head.

Dr. JEWELL cited a case of zoster affection, occurring in a woman weighing about 300 pounds. She was seized with great pains in the region of the uterus, which extended into the inguinal region, and so into the back. These were soon followed by chills and burning pains in the skin, following the course of the crural nerve, and finally red lines appeared over the tract of the irritable and painful nerves, which were followed by a herpetic eruption, and the blisters were always preceded by the pain, and they extended from the hips downward. The irritation continued until the trouble about the uterus began to get well. There

was a clear connection between the severe congestive trouble about the uterus and pelvic irritation and the cutaneous eruption.

Dr. WEBBER inquired whether there was any pelvic cellulitis present.

Dr. JEWELL replied that there was none at all, and that the trouble was entirely reflex.

Dr. HAY referred to the case of a gentleman, who had been in the habit of wearing his pantaloons without suspenders, and after a while became afflicted with pains, which extended down into the hip and testicle. The pain recurred daily, and was always relieved by change to the horizontal position, and would immediately disappear when he went to bed. The man did not obtain any relief by treatment, and his case came to be regarded as one of incurable neuralgia of the testicle. About three years ago a herpetic patch made its appearance upon the inside of the thigh, upon the same side, which became worse during the day, and reached its maximum at night, and was almost entirely well again in the morning. This condition of affairs continued, and one day, while examining his patient, he suggested to him to wear a pair of suspenders. He at once put a pair on, and within forty-eight hours his pain entirely disappeared, and with it the herpetic patch. It was regarded as a clear case of reflex neurosis.

Dr. MILES referred to his own thigh, which was once corded sufficiently tight to produce anesthesia for some time. He afterwards contracted chills and fever, but the leg below the spot where the cord was placed never got chilly.

Dr. JEWELL remarked that there were two important points in these cases with regard to pathology. If the nerve has been injured, the question arises, How is the trouble produced in the skin? Is it by the production of neuritis, or is it by irritative influence, without respect to neuritis, transmitted along the nerve in such a manner as to irritate beyond the normal nutritive action? In many cases the explanation must be by the last method.

The next paper was read by Dr. Roekwell, of New York, entitled, "A Survey of the Field of Electro-Medicine, with special Reference to its Physiological and Therapeutical Relations to the Nervous System."

MISCELLANEOUS BUSINESS.

Dr. HAMMOND nominated for membership Drs. S. Oakley Vanderpoel, T. Edwards Clarke, and Clinton Wagner, of New York.

Dr. MASON nominated Drs. J. P. Gray, of Utica, and D. H. Kitchen, of New York.

Dr. E. C. SEGUIN nominated Dr. G. M. Beard, of New York.

The Association then adjourned, to meet at 2 P.M., June 4th.

FRIDAY, JUNE 4TH—THIRD DAY.

The Association was called to order at 2 P.M. by Dr. Jewell.

ANALYSIS OF A CASE OF CIRCUMSCRIBED ANALGESIA OF THE SKIN AFTER TYPHOID FEVER.

Dr. PUTNAM, of Boston, read a paper containing such analysis, and based his remarks upon a case of typhoid fever occurring in a male patient 18 years of age. A short time after his *apparent recovery* he noticed that slight wounds of the left hand healed only very slowly, and that certain injuries to the hand and arm gave rise to no pain. When examined, it was found that the skin upon the left arm, shoulder, left side of the trunk, and neck, up to the median line of

the body, and downward to the eighth rib, was in a condition of anæsthesia. The hand could be thrust into water of a temperature of 110° F. without inconvenience, and a pin thrust into the skin failed to cause pain. A light touch, as with a brush, on the tips of the fingers was almost invariably recognized. When the skin was sprinkled with water, each drop could be distinctly felt. His hand could be retained in water at 120° F. about two minutes, and in water at 160° from two to ten seconds.

At present the left side of the neck has recovered to quite an extent. The case was regarded as one of partial paralysis of sensation, the immediate consequence of the acute attack of typhoid fever, and was probably of peripheral origin. It was thought to be peripheral chiefly because of its definite localization. He did not, however, wish to throw out of the question the cerebral element in studying the case.

Dr. SEGUIN expressed the opinion that the cerebral element should be left in the problem, and from our present knowledge of hemiplegic analgesia, such as is manifested in hysterical women, hypnotism, and certain conditions produced while inhaling anæsthetics, he inclined to the opinion that the real cause of the conditions noticed in Dr. Putnam's case was due to some encephalic trouble.

NEW DYNAMOMETEER.

Dr. A. McLANE HAMILTON, of New York, exhibited a new dynamometer in which a rubber bulb is substituted for the spring in the instrument in common use. The instrument consists simply of a rubber bulb containing a colored fluid which is attached to a glass tube, having an index. The principle is that it requires a certain amount of pressure to condense the air in the tube above the fluid, which is marked upon the index.

FRACTURE OF THE ODONTOID PROCESS.

Dr. HUX, JR., of Albany, presented a specimen removed from a woman, æt. 50 years, accompanied with a history of previous injury which caused her to lie insensible for several hours, after which she awoke and walked some distance, ascended a flight of stairs, etc. There were no convulsions or tremors, but there was almost complete anæsthesia of the legs. She rode to the Alms House, walked from the wagon to the house, walked up-stairs, and seemed to have no inconvenience in so doing. She remained in the Alms House a few days, and died. At post-mortem the odontoid process was found to be fractured without rupture of the transverse ligament, the atlas dislocated from the axis, and the condyles upon the left side fractured in three places. The patient was not any time completely paralyzed.

NEURALGIA AND OTHER NEUROSES ARISING FROM CICATRICES OF THE SCALP, AND THEIR SURGICAL TREATMENT.

Dr. LENTE, of Cold Spring, N. Y., read a paper upon the above subject, in which he referred to several remarkable cases of neuralgia, amanosis, and other visual disturbances, which had been completely and rapidly cured by the excision of old cicatrices upon the scalp. He argued that more should be done than simply to incise the cicatrix, and that it should be removed.

PIGMENTARY DEPOSITS IN THE BRAIN AS THE RESULT OF MALARIAL POISONING.

Dr. HAMMOND, of New York, presented a paper upon the above subject, in which he gave the results of clinical observation and experiments upon animals.

He regarded the pigment in these cases as being of *splenic* origin. He was of the opinion that, especially in malarious districts, many nervous disorders were induced by the deposit of this pigment in the brain.

Dr. MILES, of Baltimore, spoke of the effect upon the nervous system noticed as the result of malarial poisoning, and cited one case where the chill was represented by an epileptic paroxysm which was followed by the fever and sweating in their regular order.

HEMIPLEGIA WITH CLOT UPON THE SAME SIDE OF THE BRAIN.

Dr. HAY, of Chicago, presented an interesting specimen of this kind, removed from a female patient æt. 55 years, in whom there was hemiplegia of the left side, face not involved, and the tongue could be protruded without deflection. The patient jumped from a railroad train which was moving at a rapid rate and was picked up insensible, in which condition she remained for about three weeks. She suffered from incontinence of urine and feces. At post-mortem a meningeal clot was found over the frontal convolution, upon the left side of the brain, about a line in thickness, three-fourths of an inch in length, and about the same in width. No morbid conditions were found in any other part of the brain, and the clot was limited to this region.

Dr. HAMILTON remarked that he had produced convulsions in animals upon the same side of the body with the irritation produced in the brain.

At this hour the Association passed to the transaction of miscellaneous business.

Dr. George M. Beard was recommended by the Council for membership, and elected by the Association.

A communication from Dr. S. WEIR MITCHELL was read containing his resignation as President of the Association, whereupon Dr. Clymer, of New York, offered a resolution elevating Dr. J. S. Jewell, of Chicago, to the Presidency as if reported upon by the Committee on Nominations, which was unanimously adopted.

The Council made a report by which Dr. E. H. Clarke, of Boston, was made first Vice-President, and Dr. F. D. Miles, of Baltimore, second Vice-President, which was accepted and adopted.

Dr. HAMMOND withdrew the nominations which he had made at the previous meeting, and offered the following resolution:

Resolved, That, as the number of active members of this Association is limited to fifty, it is inexpedient to elect to membership superintendents of lunatic asylums, but that in this action the Association does not wish to depreciate the labors of these gentlemen, and is further influenced in this action by the fact that there is already an association composed exclusively of superintendents of such asylums.

After considerable discussion the matter was referred to the Council for report at the next session of the Association.

Drs. Clymer, Hammond, and Hamilton were appointed as Committee of Arrangements to act in conjunction with the Council for the session of next year. It was decided to hold the next session of the Association in New York, commencing on the first Wednesday in June.

After passing the customary vote of thanks to the officers of the Association and to the Committee on Organization, the Association adjourned.

UNREAD PAPERS REFERRED TO THE COUNCIL.

A Note upon the Clinical Effects of Conium, by Dr. William Pepper, of Philadelphia.

The Structure and functions of the Ganglia on the

Posterior Roots of the spinal nerves; A Case of Insanity caused by Wound of the Brachial Plexus of Nerves; A Case of Diabetes Insipidus caused by Disease of the Meatus Auditorius Externus;—all by Dr. J. S. Jewell, of Chicago.

Contributions to the Study of Basal Meningitis, by Dr. T. A. McBride, of New York.

Insanity in Children following Masturbation, by Dr. Frank K. Kinnicutt, of New York.

Tables Showing the Results of the Use of Phosphorus in Neuralgia and other Painful Affections, by Dr. N. B. Emerson, of New York.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from May 30th to June 5th, 1875.

RANDOLPH, JNO. F., Surgeon.—Relieved from duty at Camp Robinson, and assigned to duty at Fort D. A. Russell, Wy., T. S. O. 64, Department of the Platte, May 29, 1875.

FRANTZ, J. IL, Surgeon.—Assigned to duty as Post Surgeon at Fort Preble, Me. S. O. 105, Military Division of the Atlantic, May 26, 1875.

WEEDS, J. F., Surgeon.—Assigned to duty at Nashville, Tenn., as Post Surgeon. S. O. 71, Department of the South, June 2, 1875.

LOUNG, L. Y., Assistant Surgeon.—Granted leave of absence for one month. S. O. 33, Department of Arizona, May 18, 1875.

HARVEY, PHIL. F., Assistant Surgeon.—When relieved by Surgeon Frantz, assigned to duty at Fort Independence, Mass. S. O. 105, c. s., Military Division of the Atlantic.

HOFF, JNO. V. R., Assistant Surgeon.—Granted leave of absence for one month. S. O. 64, c. s., Department of the Platte.

SKINNER, J. O., Assistant Surgeon.—Relieved from duty in Department of the Columbia, and to report in person to the Commanding General, Department of the South, for assignment to duty. S. O. 111, A. G. O., June 4, 1875.

HAMILTON, JNO. B., Assistant Surgeon.—Assigned to duty at Fort Colville, W. T. S. O. 64, Department of the Columbia, May 19, 1875.

Medical Items and News.

ZIEMSEN'S CYCLOPEDIA OF MEDICINE.—On page 290 of vol. iii., second text line from the bottom, the word "ounces" should read "drachms." As the error might lead to serious consequences, we would thank our exchanges to give publicity to this notice.

EXAMINATION IN STATE MEDICINE.—Cambridge University, England, has issued a programme for an examination in so much of state medicine as is comprised in the functions of officers of health, to be held in Cambridge, beginning on Tuesday, October 5, of the present year. Any person whose name is on the Medical Register of the United Kingdom may present himself for examination, provided he is twenty-four years of age.

The examination will be in two parts. Part I. will comprise—physics and chemistry, the principles of chemistry, the methods of analysis, with especial reference to analyses (microscopical as well as chemical) of air and water; the laws of heat and the principles

of pneumatics, hydrostatics, and hydraulics, with special reference to ventilation, water supply, drainage, construction of dwellings, and sanitary engineering in general. Part II. will comprise—laws of the realm, relating to public health, sanitary statistics, origin, propagation, pathology, and prevention of epidemic and infectious diseases, effects of overcrowding, vitiated air, impure water, and bad or insufficient food, unhealthy occupations, and the diseases to which they give rise, water supply, and the disposal of sewage and refuse, nuisances injurious to health, distribution of diseases within the United Kingdom, and effects of soil, season, and climate. All applications for admission to this examination, or for information respecting it, should be addressed to Professor Living, Cambridge.

A ZOOLOGICAL AND BOTANICAL GARDEN covering sixty-seven acres is about to be established in the northern suburbs of Cincinnati, under the auspices of the Cincinnati Zoological Society, who have already over \$100,000 to devote to the improvement of the grounds, erection of buildings, etc.

THE CENTRAL NEW YORK JOURNAL OF MEDICINE AND SURGERY is the name of a new periodical to be published in Syracuse by Dr. E. B. Stevens, who for several years was editor of the Cincinnati *Lancet and Observer*. The first number is to appear on the first of July.

MISSOURI.—The next session of the State Medical Association convenes in St. Louis, in April, 1876.

M. ADRIEN DELAHAYE, a well-known French publisher of medical works, is dead.

DR. ROZIER COZE, late Professor in the Faculty of Medicine of Strasburg, died recently at the age of eighty years, at Oberbruck, in Alsace.

M. PASTEUR being unable to continue in the performance of his professional duties, retires upon an annuity of \$1,160, and a pension, voted him by the French National Assembly, of \$2,325.

SMALL-POX IN FRENCH HOSPITALS.—For years past small-pox has been treated in the general wards of the Parisian hospitals, but of late the disease has been making such inroads in the French capital, that efforts are being made by the physicians to secure separate wards for the treatment of variolous patients.

THE MONASTERY OF ALTENBERG have advertised for a resident physician, who is to receive, besides his board and lodgings, a salary of about \$100 per annum. For this munificent salary he is not only to give his professional services to the sick in the monastery, but will be expected to take charge of the hair and beards of the holy brethren.

WEEKLY BULLETIN OF THE MEETINGS OF MEDICAL SOCIETIES.

Monday, June 14.—Obstetrical Sect. of the Academy of Medicine; N. Y. Soc. of Neurology and Electrology; Pathological Soc. of Brooklyn.

Tuesday, June 15.—N. Y. Obstetrical Soc.; N. Y. Dermatological Soc.; Medical Society of the County of Kings; Newark Medical Assoc.

Wednesday, June 16.—North-Western Med. and Surg. Soc.

Thursday, June 17.—N. Y. Academy of Medicine; Medical Assoc'n Eastern Dist. of Brooklyn.

Friday, June 18.—Medical Library and Journal Ass'n.; R. S. Guernsey, Esq., of the N. Y. Bar, "The Penal Law relating to Suicide in Ancient and Modern Times."

Original Communications.

SOME REMARKS ON SCARLET FEVER.

By EZRA M. HUNT, M.D.,

METTCHEM, N. J.

HOWEVER desirable it may be for each of us to be equal to a great operation, it is far more desirable to be equal to the more frequent duties of every-day professional life. There are diseases that the average practitioner must very frequently meet, and upon which nearly all, save specialists, are to illustrate and enforce their skill. We relict from saying anything about scarlet fever, because so much has so ably been said, because we have no new theory to offer, and because we are conscious of the diversity of opinion which obtains among our best practitioners as to its cause, phases, and treatment. But to record what we know, or think we know, is the clinical way to get at individual experience, and thus to make medical comparisons which are not odious. So we may get wrong views rubbed out of us, or mutually help to rub them out of each other. This is my only excuse for desiring to make a few observations as to some typical cases of the disease, and then to use them as a text for some reflections as to its cause, conduct, and treatment.

Dec. 22, 1874, I was called to see H. L., a girl of 14 years, of florid complexion, robust form, and full health, who had never had a serious sickness. I found her with excessive temperature, rapid pulse, and seeming quite sick. As diphtheria and various forms of throat disease were prevalent, I examined the throat, of which she complained slightly. I found it a little reddened, but with no swelling or sign of deposit. I prescribed chlorate of potassium and ipecacanha, with a mild cathartic. The next morning there was but little change of symptoms, except that the general expression was that of a person about to have some severe development of disease.

The pulse was quick and wiry, and there was a pallor and slight blueness of lip, denotive of bad circulation. There was headache, but no delirium or stupor; no cough, and no sign of local complication. Catamenia had been suppressed. I said to the friends that I had apprehensions of a malignant type of fever. As I was very unwell, Dr. W. saw her in the evening, and came to my house. Our views of treatment coincided, but we were not able to complete diagnosis. Quinine had been ordered in the morning, and she was sustained by food. It was agreed that she should have stimulants during the night, and the Doctor remained with her. About midnight the prostration became more decided, and the circulation seemed greatly enfeebled. Stimulants were freely used, but she rapidly sank, and died about 7 A.M. We could only say that she had died of a very low grade of fever, or from the shock of some intense morbiic paralyzer. Our village had been for a year or more unusually exempt from scarlet fever, and there had not been, so far as I know, a case within three miles. The day after this lady was taken sick, her brother was detained from his business in New York by a cold and dryness of throat, so that he kept his bed for the day. He went the next day to the city, but was walking about home the rest of the week, having loss of strength and appetite. He had no eruption, and no sign whatever of scarlet fever.

A little sister of 12, in full health, was invited to stay a few days at another house with a friend. Six days after her sister's attack she came to be seriously sick,

under the care of Dr. Norton. In 36 hours I was summoned in consultation, as a rash had appeared. Her disease was manifestly scarlet fever. Here again there was high temperature (103°), and excessive fever, but no emesis, and very little sore throat. I saw the case but twice, and, although it was severe, no untoward symptoms presented themselves. After ten days I heard of her as making a good recovery. On the twenty-first day after her attack I was shown a specimen of the urine, largely laden with albumen, and at once expressed my anxiety, although no alarming symptoms had made their appearance. The next night I was sent for in consultation, and found the patient in laboring respiration and profuse perspiration, with nervous engorgement, and such pleuritic effusion and lung complication as betokened impending dissolution. She died the second day after.

A sister of Dr. N., at whose house the brother and other members of the family had been, was taken sick.

I also saw her when the eruption appeared. She was very sick for four or five days, with pulse at 120 to 130, and temperature ranging from 102° to 106°.

The fever was kept down with cold sponging, and ipecac and chloras potassium given at first, and afterwards chloras potassium and tincture muriatis ferri. The throat was inflamed. But little swelling of gland and no exudation occurred. Care was taken to keep the throat clear of mucus, to gargle frequently with cold water, and a slight embrocation was used externally. She made a slow but satisfactory recovery.

When the second daughter of the former family was taken so severely ill away from home, her eldest sister, who had cared for the one who had died first, was much with her. Five days after, she was taken seriously ill at her home, where the first one had died.

With a pulse of 130, and a temperature of 106°, and the history of the other cases, the coming evil could be easily predicated. Yet there was no stomach disturbance, no redness of the tongue, and very slight soreness of throat.

I at once directed frequent sponging with cold water, and the use of drinks as refrigerants, besides giving a mild cathartic, a little chloride of potassium, and tincture muriatis ferri, endeavoring to regulate all surroundings as to air, temperature, etc. We had considered the hygienic condition of the house unsatisfactory before. At my request Drs. Norton and Baldwin were sent for in consultation. We had no proof from the case itself which would specifically identify it as scarlet fever, save perhaps the excessive temperature. No signs of eruption appeared until the fifth day, and then after most thorough and continuous sponging. It was then only scarlatina variegata, the eruption appearing over the chest, and a redness streaking out a little on the limbs. It varied much in distinctness, and would alternately appear and disappear. The temperature was taken twice per day, and varied from 102° to 104°. Pulse was 130 to 140, and lacked tone. Great reliance was placed upon frequent sponging; and because of the manifest debility, wine-whey was used as a drink. Twelve grains of quinine in three-grain doses was administered daily. Sheets and bed-clothing were changed, and aired with what appeared as "fussiness." The room itself was carefully cared for. We regretted that we were not able to change surroundings by removal from room to room. The throat became much sorer than in any of the other cases, with slight swelling of the gland on one side. One tonsil was in part covered with a diphtheritic patch, which was promptly touched with solution of nitras argenti. For one week there was very little change as to pulse, temperature,

or general symptoms, but after this there was gradual improvement up to the twenty-first day, when albumen appeared in the urine, and swelling of the face occurred. Microscopical examination also revealed casts in the urine. Milk had been used pretty freely before, but now eggs were added. Pulvis purgans was given each day, sufficient to cause one or two watery evacuations. The skin was moistened by means of a vapor-bath, very hot bricks saturated with vinegar and water being first used, and afterwards a steaming apparatus. There was slight swelling of the feet, but no anasæra, and after two weeks the puffiness about the face had subsided. At this writing albumen has nearly passed away, and the patient is promising a good recovery.

In the meantime the brother before referred to, who had been confined to his bed one day and continued weak, was found to have very decided albuminuria. Between two and three weeks after his sick day, Dr. Flint had prescribed for him, and regarded his case as an acute one, probably dependent upon the scarlet fever poison. There is, however, some question whether his case is not to be regarded as chronic nephritis of a little earlier inception.

There were two other boys in the house who, at first, were unavoidably exposed, but did not contract the disease. There have been, so far as I know, but twelve additional cases of the disease in the village since those here mentioned, three being in one family, in which one died of convulsion before eruption, and three in another, in which one also died. The other cases were mild in their course. In all save one there had been known contact of persons in the families, but not of all those attacked.

During a practice of twenty years I have seen an ordinary amount of scarlet fever, and in these epidemics it has exhibited some malignancy. Its severity has been localized in families, so that it has not become very generally prevalent. In one case a family of five children died within one week. None of these had an eruption, save the last which I saw in consultation, in articulo mortis. None others in that sparse neighborhood died of it. A young lady, who aided in nursing these, had it quite severely, but with no alarming symptoms.

The first thing for a doctor to do when called to a case of scarlet fever is to recognize that he has in hand a case of poisoning. All poisoning requires wide-awake diligence, and prompt resort to prompt measures. It is not a matter of perfunctory direction. The peril is so impending that outside the sphere of antidotes there is a therapeutics of toxicology. The doctor must at a grasp take in the whole situation, as would a general amid a raid, and see himself that things are done. This is easy for a surgeon, for he is an operator, and the operation seems like an achievement; but the hygienic, counteracting preliminary work about a still disease is as utterly devoid of éclat as is confluent small-pox. It is constantly shown how severity of outbreak is mitigated by previous preparation and improved surroundings. We ought to learn very much as to all these zymotic diseases from what occurred when inoculation was not in vogue. How dreadful was the small-pox then as a scourge. Yet how wondrously was it shorn of terror just by proper methods of preparation. It is the record of what prophylaxis can do for disease, and ought to instruct us much as zymotic diseases multiply upon us. So also should the history of cholera, of which the medical officer of the Privy Council of England says: It has "the faculty of infecting districts, in a manner detrimental to life, only when the atmosphere is fraught with certain products susceptible, under its influence, of undergoing poison-

ous transformations. Through the unpolluted atmosphere of cleanly districts it migrates without a blow; that which it can kindle into poison is not there."

I know of no disease in which, in the start, diligence is of more importance than in scarlet fever. The vomiting, or the system depressed below the point of emesis; the intense heat, beyond that of any other disease in its inception; the wiry pulse, and the general malaise, show that some vicious and tissue-consuming force has found its way into the system, which hastens to disorganize vital fluids, and which strikes at the centre of life. It is one of those diseases which, of itself curable, is dangerous by reason of the incurable damage it has wrought. It is much easier to deal with such a disease as a cause, and as such abate it, than it is to medicate its effects. It is one thing to meet a disease and contend with it, and another to doctor the damages it has made. For instance, the poison may make rapid rise in temperature and intensely involve the capillary system, and yet by prompt measures be restrained; but if defibrinization has to a great degree taken place, and the mucous membrane has become "infiltrated with fibrous exudation," we have new factors to deal with. The fact that we may not remedy such a state does not militate against the fact that we may arrest the disease, so as not to have to deal with its irremediable disintegrations. The bodies of those who die have "blood poor in fibrine, thin and dark." It seems as if a poison had been infused in the blood which has the effect to separate fibrine as it may be done after bleeding, and so disorganize the blood as that it ceases to be a vital fluid.

In the start we have plainly to do with a toxic element, and must treat it accordingly. We must do with it as with all poisons for which we have no chemical antidotes. The chief danger is the amount, and we must make it harmless by dilution. We are to be ever so busy, not ten days after, but in the early hours in which the poison begins to proclaim its presence—1st, to keep diluting; 2d, to prevent the administration of more; and 3d, to provide the most natural and rapid facilities for its elimination. Thus it is to treat the disease, instead of waiting to treat its advanced destructions. Cases become critical, just as in poisoning, from the quantity more than the quality of the poison. The chemists define *quantivalence* to be "the observed power, force, or value for work of an atom," and it is this aggregated and manifested power of disease atoms which must be reduced to the minimum. *Air and water* are the great diluters, and must be looked after as important reliances in reducing the concentration.

If we always had our way we would not allow a patient much sick with the disease to be kept in the same room more than a day at a time. The bed-clothing as well as the body clothing must be frequently changed, and air freely admitted, and water used as we shall specify further on. In connection with this it is well to avail ourselves of the best of the class of disinfectants, although we are to remember, as Harris recently remarks, "that much that passes for disinfection and sanitary cleansing are such only in name." The vapor of tar or vinegar is generally not unpleasant to the patient, and can easily be secured from a stove or cooking lamp by heating a little of either in a tin basin. This must not serve us in the place of chlorinated lime or Labarraque's solution, either of which we are in these cases slow to supersede by any of the phenyl preparations. But after all, air and water help most in preventing the reinhalation of morbid product. In common with Watson and others, we believe the aggregate mucous follicles of the mouth and the throat, and especially the tonsils, be-

come *sources of poison*, which is received into the lymphatic system, or even more directly into the circulation, and so aid bad air in its readministration. We therefore like that the throat be frequently cleansed without being strained, and that little or no saliva be swallowed. Cold water at first answers better than medicated gargles, and astringents should not be too early used. It is very important to keep the mouth in order, for glandular complication is always troublesome. Much of this in its inception may be due to local absorption or to the mechanical obstruction by which the ducts of the various glands and follicles about the mouth are occluded and the ear seriously affected by the closure of the Eustachian tubes. The iodine liniment is good for the enlarged gland, and an oil-silk covering. We are to accomplish the third point, or to afford natural and rapid facilities for the elimination of the poison, chiefly through the medium of the skin and kidneys. But it happens that these are the very parts primarily attacked in scarlet fever. Hence we need the most astute diligence in restoring or preserving these functions. Our chief deliverance must accrue through these emunctories. A *right temperature and moisture of skin* are the chief methods of dealing with it, and the free use of fluid the chief method of action on the kidneys. The remedy in the inception of scarlet fever, *therefore, is cold water within and without, and the thermometer is the most valuable indicator for treatment.* Heat, internal and external, is the most prevalent symptom, and must be combated not only in itself, but because of its disorganizing effects. There is paralysis of the functions of vital organs similar to that of *coup-de-soleil*, although more marked on the heart than on the brain. The intense heat suspends moisture and radiation. So there is suspension of insensible perspiration and "a height of temperature inconsistent with life." Parkes says the temperature of the body is, 1st, the result of chemical changes of the food and the conversion of mechanical force into heat and direct absorption without. Here it is also a result of a toxic agent introduced from without. Opposed to the natural heat we have a wonderful balance and stability of animal temperature preserved in all climates by evaporation from the surface of the body. In scarlet fever the fearful factor is that internal heat production is augmented, and evaporation from the surface and from the lungs is much suspended. It would be instructive, did space permit, to take such authorities as Parkes, Weymyer, H. C. Wood, on "Thermic Fever," etc., and follow out the parallel and show how also the heart and nerves are paralyzed, and nervous tissue altered by the heat instead of by the poison. So soon as the heat is 100° F. we should see an indication for cool sponging and refrigerant drink in some form. The thermometer should be the pathognomonic symptom. This method should be followed up sufficiently often to limit the temperature.

How this shall be done physicians may differ, and upon it have fine opportunity for close observation. One, like Vogel, recommends innaction, because oil regulates temperature. It is also to be noticed that in this treatment both he and Schuceman keep the temperature of the room at 60° and really use the oil to prevent sudden capillary changes. The latter even advises a lower temperature and oft-repeated ventilations, and that the windows in his cold climate be kept open three hours per day. Thus the lungs have extra chance in their work of evaporation as well as the skin. It is a cold-air bath instead of a sponge-and-water bath. Others rely much on refrigerant drinks, and add cooling medicines as aiding the effect of

liquids. Some are content with simple cold water if there be no other way to encourage the use of liquids: while others prefer liquids slightly warmed when they can be made sufficiently palatable to be taken in large quantities. These means may aid in reducing temperature, which is generally equivalent to saying *aid in eliminating the poison.*

The sponging is not to be routine sponging, but such as is followed up under thermometric guide, and continued, if thus indicated, long after the eruption. The highest triumph of the medical thermometer will yet be in measuring zymotic diseases. Our great trouble in the use of cold water externally is to find a nurse who has both judgment and industry enough to do duty at each oft-recurring crisis of rise of temperature. The doctor needs to be on the alert. In this as in all poisoning cases time is a controlling factor, and delays are fatal.

Changes take place which were preventable, but having once occurred are irremediable. Vigilance in scarlet fever must be largely prophylactic, or rather "phylactic," all the way through. The use of the water must be by sponging a part and then drying it without rubbing and without undue exposure of the whole body. As to cooling internally and seeking relief through the kidneys, which at the start have less interruption of function than the skin, cold water is the chief reliance. We have never forgotten the remark of Dr. Beck, that the best and chief diuretic is water, and so it is the chief refrigerant. The stomach is sometimes disordered by acid drinks or by making the water too much the vehicle of other things, yet it is often necessary, in order to secure quantity and suit the stomach, to use unstimulating teas or drinks, such as lemonade or tamarind water, although we confess to prejudice against much drink-medication at this stage. Starting, then, with the fundamental idea that we are to regulate the temperature by water within or without as the thermometer may indicate, we must then seek to know how far medicines are to avail. Ipecacuanha, in the earliest stage, combined with chloras potassium, acts not as a nauseant and depressant, but as a febrifuge and a soother of mucous membrane. Dover's powder is seldom indicated unless to avoid a second night of great restlessness which sponging fails to relieve. The use of quinine would seem proper as an anti-pyretic, but in fevers having no periodicity, we have seldom found it available at the start; after the first few days, when the fever has commenced to decline, we have found it more valuable as a daily tonic. Here at first the fire is so fervid and special (Promethean) that, as in yellow fever, quinine has no specific action.

We are chiefly to rely upon that class of remedies which is *unfavorable to fermentive or destructive processes*, for there is in this disease a deprivation of the blood by which its vitalizing agency is retarded. The question (hypothetical) occurs whether sulphite of soda or other neutral salts, or aromatic spirits of ammonia, may not act by delaying blood changes; just as after bleeding, by adding to the blood a solution of neutral salts, you may retard when you do not prevent coagulation. But the chief remedies on which we are to rely are those like chlorate of potassium, which has practically shown itself to be arrestive of adynamic or morbid decompositions, or such as tinc. muriatis ferri and the mineral acids, which arrest fermentive processes. To these add, when needed, such articles as vinegar and alcohol, which, as having undergone fermentation, are to a great degree incapable of change, and arrest it where occurring. Although we know not the mode, yet the fact from practice is growing more

and more into admission, that there is a class of remedies which, taken into the system, do tend to arrest abnormal disintegrations. In some cases they do so by combinations. In others it may be by mere presence (catalytic), just as in chemistry starch changes into sugar in presence of sulphuric acid. We are not sure but that the chief value of alcohol will hereafter be shown to be that in itself, and as in part changed into acetic acid in the stomach, it will not undergo but will retard fermentative and putrefactive changes, as with facile quick step it reaches to blood and tissues. The same is true of acetic fermentation. We like in all zymotic disease those remedies which in part reappear unchanged in the excretions, or those which change to neutralize morbid conditions, and generally in so doing impart acidity to the urine. Of such we believe chlorate of potassium and tinc. muriatis ferri among the chief. These seem to us to act better together than either alone, the best chloras potassium being used in about three or five grain doses, with from five to ten drops of the tincture. The action of the potassium in stomatitis, and of the iron in erysipelas, is so marked that it seems to us they have an arrestive effect in such like morbid decompositions. We believe it quite important to have the tincture muriatis ferri in its purest form, in which, and in which only, it contains the "sesquichloride of iron, muriatic acid, and alcohol, and from the reaction of the last two ingredients, muriatic ether." "It is," says Wood, "possessed of peculiar properties, probably in some measure due to the ether which it contains. It increases the daily urinary secretion. We believe it of service in prospect of the kidney desquamation, which is to be regarded as a part rather than a complication of scarlet fever." Even during the eruption "the urine contains quantities of detached epithelium, and often traces of albumen," from the local hyperemia, without croupous inflammation. We are learning to pay more attention to the kidney, because very early it is thus called upon to do work in the line of getting rid of abnormal product. Next to the skin it is here the chief emunctory, and just because it is so apt to be locally or functionally affected, must have attention, and because of the extra demand, the irritation of function and the tubal nephritis which often occur therefrom.

The intense general depression which we often have at the start is owing to the toxic effect upon the blood and nervous system, and relief is mostly to be sought by the most vigorous reduction of heat, according to thermometric indications, and the diligent use of the remedies spoken of. Alcohol may also be used in some cases for its anti-fermentive and sustaining effect. Both it and ammonia serve in cases of exceptional severity as stimulants, which aid to keep the heart in action and prevent blood-change, death often occurring from paralysis of the heart or from a change in the life-cohesion of the blood itself. Further than thus far named, we think medication has not very much to do in scarlet fever. We see cases where water alone does not seem to suffice as the cooling and diuretic drink; but some refrigerant needs to be added, or, as noted before, some change in form of a cool tea, which will be more relished. Common tea or sage tea sometimes appear of value by the action upon the kidney of the tannin they contain. We even hesitate to name diuretics, etc., lest this should bring physic into prominence. Like Sir Philip Sidney with his Arcadia, we have a model of how successfully to meet severe cases of scarlatina, if at all seen in-time, or with chance for any treatment. The line of direction of treatment is plain, and the indications for the

variations required not obscure. It is unsafe to present an unvarying programme, for no disease is made for a Procrustean bed. Yet there are few diseases in which the treatment is so uniform, and, if followed out in time, we believe we may say so successful. The heat-regulating treatment, and the attempt to preserve the great emunctories intact, and to prevent reinhalation or re-poisoning in any form, is the primal idea. Next to it are the remedies already indicated, and that care of surroundings and attention to litters which no formula of treatment can describe.

During the high temperature of the disease, all foods given should be in liquid form. Generally in the earlier stage nutrients do not need to be pressed, as the depression is not dependent upon the failure of food or of the tissues to ferment it, but to toxic influence. Milk is more frequently indicated than any other food, and eggs when anything more solid comes to be allowed. As the mucous membrane of the stomach and the alimentary canal are not in a state for free secretions of digestive fluid, we need the blandest food, and breadstuffs are often used too early. Broths, gelatine, and a little stewed fruit (not canned), and fresh soda-cracker are among the aliments proper.

As to the etiology of scarlet fever, we have but little to say, except as starting thought and study. It is good to have well-defined hypotheses, and then theory, that we may sift facts and know whether they mean or justify a settled medical belief.

That the disease is a distinct entity, and is infectious, the following case indicates: I had attended a severe case of scarlet fever in the only child of a family residing near the Raritan River. The grandmother, some six weeks after, went on a visit to a neighborhood four miles distant, where there had been no cases of scarlet fever for a year. She took with her an old box which had in it a silk dress, and which had been under the bed of the sick child. For two weeks after her arrival no case of scarlet fever appeared among the children of the family where she was. But one Sunday she opened the box which had in it her dress, and put it on, and the next Sunday scarlet fever appeared in that family. Before I was called to see these cases I was in attendance upon one of the children of the next neighbor, some 200 yards distant, who had just broken out with measles, contracted, as was afterwards found, by sleeping with a cousin in Plainfield two weeks before. The measles eruption was as characteristic and unmistakable as I have ever seen. Soon after it appeared another eruption appeared, mostly on the part least broken out with measles, and this was as distinctly scarlet fever. The one was much the most distinct on the one side, and the other on the other side. On the two arms especially the contrast was marked. I then found that the child had been, the Sunday one week before, at the house of this neighbor where the children had just commenced complaining. The case was a severe one, the scarlet fever being associated with suppuration of the parotid gland. The child recovered. In one week the second child was taken with scarlet fever, which ran its course not severely, and a week after broke out with measles, the scarlet eruption having subsided. I had thus additional proof of infection, and of the possibility of the two diseases existing at the same time. While infection is the chief source of these zymotic diseases, we do not believe it necessary to assume either that it or contagion are the only sources. They have their laws of origin and propagation, and spread mostly by infection; yet the same conditions which finally occurred and produced cholera in India, might occur and produce it elsewhere. Given the same combina-

tion of conditions at New Orleans, and it might originate there. Whether, as a matter of fact, it does, is a question to be settled only by aggregation of facts and difficult exclusion of all outside possibilities. The spontaneous generation of any given disease, or of any new disease, is quite a different question from the spontaneous generation of animal life. I know not why the combination called gunpowder did not get together long before, why lucifer matches waited for the present century, or why nitro-glycerine so long waited its union. Filth has its laws as well as other chemistries. It is quite possible that while the zymotic diseases spread by infection mostly, that once in a thousand times just that correlation of degenerations may occur, of which the result is this or that disease. A manufactory for making nitro-glycerine and giant-powder in this State had to import from Germany an infusorial earth needed. Some of the giant powder contains 25 per cent. of it. In a swale or depression covered by a swamp of low bushes near the factory, some one found a whitish earth. Examination shows it to be the very article they were importing, entirely made up of the silicious skeletons of diatoms. I know as little how they got there as I know why some diseases which we get from abroad or from infection are found on the spot. We know no reason why the chemistry of decay and its combinations should not have as many originalities as the chemistry of life. Some day we will know more on these points, as we are getting hold of some great outlying and underlying truths. It is worth while to voyage about a little, as did Columbus, and to collect drift-wood, only we must not cry land too early. But we feel sure of some things about these zymotic diseases, and that some of the indications are plain. We want that each and all of us shall watch closely, and see how far, in addition to the principles of treatment set forth, we may get aid from proper surroundings. Bad sewage and sinks do not all the foul work. Bad kitchens, close basements full of the fungus of dampness, uncleaned corners up-stairs, dirty drawers and closets never scrubbed or aired, furniture never washed, soiled carpets used more than that of parlor, but not shaken as often, soiled beds and manifold neglects of good old-fashioned house-cleaning, now and then let a disease out of the Pandora-box, or make it rampant when it comes along. Doctors often fail, not because of a weak science or art, but because conditions of failure are all about them. There is much twaddle about the uncertainty of medicine, and the failure to find out remedies. There are scores of physicians in New York City so skilled in this and some other diseases, that it would be no vain boast to claim they could stamp out the disease as Hamilton did cholera on Blackwell's Island, if only they can command and execute. Indeed, we believe that much can be done in each family to mitigate the severity of the disease in those attacked after the first one, if the physician will see to it that there is special ablution, extra care as to sleeping apartments and food. It is hard to get credit from anybody for preventive treatment, but much is to be done for the family in which such a disease commences, and the doctor should regard each child then as under his charge. We often have to blame ourselves that we do not look more carefully after the personal hygiene of each member in such cases. It is more specific than belladonna. The patient sick, too, needs a skilled and obedient nurse, and these are difficult traits to combine in one person. The appliances to be used seem to us not doubtful, but are so relative to change of temperature and to phases of the disease that we know of none of the zymotic group in which

there is so often modification as to the degree, and yet uniformity as to the remedies. Much depends upon whether the force of attack is upon throat, skin, or kidneys, and whether we are on the alert to prevent undue hyperæmia in either. With the case before us, and diligent work at it and around it, and a good nurse, we believe that such indications of treatment as we have noted may be carried out with far more success in result than the average now attained. We urge the profession to a closer testing of these views. If correct they mark out for us with some definiteness the line of treatment and the leading indications.

CHRONIC ENLARGEMENT OF THE TONSILS IN THEIR RELATIONS WITH CERTAIN SPASMODIC PHENOMENA.

By BEVERLEY ROBINSON, M.D.,

SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL (DEPARTMENT OF THE THROAT).

THE authors who recount to us the features of tonsillar hypertrophy do not mention any influence of a spasmodic nature which these masses exercise by their close proximity with nerve-trunks. That such a condition, however, is able to occasion, at times, these effects appears to us highly probable, if we duly consider some histories recently registered in our contemporary medical periodicals. To illustrate and prove this statement we beg leave to cite the following cases:

In the *Philadelphia Medical Times* of February 7th, of the present year, Professor Elsberg relates "a curious instance of peculiar expiratory wheezing, occurring in paroxysms, irregularly, but often every few minutes."

He says that, upon examination, "he found the sides of the pharynx swollen, spongy, and flabby, the tonsils and infra-tonsillar glands enlarged and nodulated, the mucous membrane of these glands infiltrated and degenerated. . . . On removing portions of the tonsils, and of this tumefied mucous membrane, these peculiar paroxysms, that had resisted all internal treatment, ceased."

Now, "to wheeze," according to Dunglison, "is to breathe with difficulty and noise, as in asthma." In other words, it is that sort of breathing which is characteristic of, and most probably accounted for by, spasm of the muscular fibres which surround the multiple divisions of the air-tubes. The assignable cause of its production in the case just quoted is evidently the compression caused by the swollen condition of the sides of the pharynx and the enlarged tonsils and infra-tonsillar glands.

Again in the *British Medical Journal*, June 7th, 1873, Dr. J. M. Haward relates the case of a girl, 13 years of age, in whom attacks of nightmare, occurring generally about an hour after going to bed, appeared caused by, and certainly were cured by the removal of, enlarged tonsils. What is nightmare? Is it not a state of passing malaise taking place during sleep, and characterized by a painful sensation vaguely perceived in some region of the body? To this latter feeling is superadded a condition of oppression and painful anxiety. The sufferer, if an adult, is unable to cry out or to move, and yet is tormented by a terrible dream, in which frightful images and ideas are conjured up in rapid succession. With children there is more agitation, and there are frequent cries during the period of attack.

In the definition given above we find both a sensory and a psychic element. With respect to the trouble of the brain—or the one to which is attributable the transformation of a painful sensation into shapes and forms which leads one's mind to that inco-ordinative frame which has been justly termed "brain delirium"—we do not intend to present any considerations. The *cause*, or rather the *point of origin*, of nightmare is what now interests us most to consider—not the *false interpretation* of the painful sensation, whatever it may be. It is this sensation—the result of derangement of certain function or functions—which reverberates towards the brain, and excites the apparition of appalling images. Generally speaking, the object to which the impression is affixed is some heavy body, whose weight is exerted in the epigastric region. This body takes all sorts of appearances, but the idea of weight seems to belong to affections of the organs of digestion, or those of the respiratory tract.

So the conception of contest or combat is annexed to troubles of the apparatus of circulation. In morbid conditions of the heart, lungs, or stomach, an unaccustomed position in sleep, or one by which the circulation in any one of these organs is retarded or interfered with, is quite sufficient to produce an attack of nightmare. If due reflection be given to these facts, we believe it will be admitted as highly probable that morbid changes in the structure of the vagi are often the proximate cause of the spasmodic effects in the lungs, which is made manifest rapidly by symptoms of oppression and anxiety.

Nightmare is then *not* a mere effect of the imagination; there is also a material cause to which it owes its production. This may be, we are aware, a morbid condition of almost any kind, and it may exist in a remote organ which is not in contiguous relations with either the trunk or branches of the pneumogastric nerves. Such fact, however, is not usually true, and in tonsillar enlargement we have, owing to the anatomical position of the tonsils, an immediate, direct, efficient cause of trouble of the sort. We are of the opinion, therefore, that by the compression which originates in an hypertrophied condition of the tonsils or lateral walls of the pharynx, we may have that perversion of nerve-force in, or that changed condition of circulation about, the pneumogastric nerves which shall produce as a result anxiety and difficulty of breathing, through their morbid and excessive influence upon the muscular layer of the bronchial tubes.

Is the influence confined to this portion of the air-passages? May not a spasm produced after this manner also affect the larynx?

Numerous are the shades of belief which exist as to the pathological nature of spasmus glottidis, or laryngismus stridulus, which are but names for a spasmodic action of the adductor muscles of the larynx, which gives rise to paroxysms of intense dyspnoea. In children, according to some eminent authorities, there is frequently an altered condition of the nerve-centres, whilst in these same cases other physicians will invariably recognize an excessive susceptibility on the part of the glottic nerves to receive reflex impressions. To us laryngismus stridulus appears to be a spasmodic affection of the purest type, which in severe cases manifests itself at the same time in many different organs of the body. In these latter instances, where there are many concomitant phenomena of the same order, there can be little doubt that the affection points to a central origin. The brain irritation which then exists to a greater or less degree has been brought on by proximate or remote trouble, and this derangement of a functional or mechanical nature may be of very

varied description. In children, teething, indigestion, the pricking of a pin or needle, intestinal worms, etc., may be the cause of brain irritation, and hence of spasm of the glottis. Under like circumstances, the mucous lining of the air-passages, including that of the larynx, is, as a rule, tolerably healthy. Where an adult is affected, there is frequently some catarrhal, or inflammatory condition of the mucous membrane of the larynx which acts as an efficient cause of the spasm. So say Meigs and Pepper in their admirable treatise on Diseases of Children. Now, to this we would append the facts which we ourselves have observed, as Resident Medical Officer in the Hospital St. Eugénie of Paris, viz., that in more than one undoubted instance where we have had occasion to care for children laboring under laryngismus stridulus, or its immediate effects, there was great hypertrophy of the tonsils and a diseased condition of the adjacent mucous membrane. Accompanying this condition, there was cervical and sub-maxillary glandular induration and enlargement, no doubt sufficiently accounted for by the morbid state existing in the fauces. According to Herard, who has made careful researches in regard to the changes of the central nervous system amongst children who have died of this disease, "the tissues of the brain and spinal marrow retained their ordinary consistence, and presented neither redness nor softening." If we examine the reported cases, especially with respect to the aspect, as seen at the necropsy, presented by the pneumogastric nerves, the statements are different. In some there was no manifest lesion of these *nerve-trunks*, or even of their *peripheral* fibres. In others the vagi were softened; some authors have found them indurated. These lesions are those which may readily follow as the result of immediate compression by a neoplasm of chronic growth, or by some adjacent organ which has increased to abnormal dimensions. We are aware that the pneumogastric nerves have been found almost completely flattened by compression due to tubercles, or indurated and enlarged cervical glands. And yet amongst these cases there are, curiously enough, examples where such compression has occasioned no visible disturbance of the function of respiration.

That like cases do occur is perfectly well authenticated. What then is the proper explanation of the examples of spasm to which we have referred in our preceding citations? To produce temporary spasm, a rapidly changed condition of local circulation is frequently essential.

Whenever a morbid mass of any kind is present in some particular organ of the body, this might be easily affected by sudden compression of nerve structure, and the probability of this symptom becoming manifest would be increased, if the nerves were in an irritable or diseased state. Instances of this description we are all of us more or less familiar with in other regions of the economy.

Why, then, may we not infer that analogous or like causes shall produce somewhat similar consequences in the lungs or larynx.

In conclusion, we offer the following as a rule of practice, viz.: *whenever chronic tonsillar enlargement is accompanied with spasmodic phenomena, having their anatomical seat either in the lungs or vocal organ, excision of tonsils (unless there be some formal contra-indication) may be performed with much resulting advantage, for by this operation we shall probably rid our patient of painful and recurring attacks of dyspnoea or oppression.*

Progress of Medical Science.

THYMOL AN ANTISEPTIC AND ANTIFERMENTATIVE SUBSTANCE.—At the suggestion of Prof. Liebreich, Lewin has investigated the properties of thymol, and has published a part of the results at which he arrived. He states that this substance, the formula of which is $C_{10}H_{14}O_2$, is a benzol obtained by distillation from the oil of thyme, and consists of highly aromatic white crystals soluble in 1000 parts of hot water. A solution even as weak as this exhibits all its peculiar properties. He found that saccharine fermentation was wholly prevented by a $\frac{1}{16}$ per cent. solution of thymol, while solutions of carbolic and salicylic acid four times as strong were not nearly so efficacious. The thymol solution also at once arrested a fermentation which had already begun. The quantitative determination of the loss of weight by the process of fermentation gave even more striking results. He found that milk treated with the thymol solution did not coagulate till twenty days later than when mixed with the same quantity of simple water, while it remains perfectly sweet and free from mould at the end of five weeks. The same was the case with white of egg after eleven weeks. Putrid pus, when mixed with the thymol solution, lost its fetid smell, and remained in this condition until it dried up. Urine similarly treated did not on an average show signs of decomposition till the end of five weeks. He declares, moreover, that thymol is capable of arresting or preventing the action of putrid pus upon the animal system, and is decidedly deodorizing. The high price of the article he regards as of minor importance, because it may be used in such dilute solutions. When taken into the mouth a $\frac{1}{16}$ per cent. solution caused a slightly burning and astringent sensation. When taken into the stomach it appeared to prevent fermentative changes, but not to interfere with digestion.—*Centralblatt f. d. med. Wissensch.*, May 1, 1875.

CROTON CHLORAL HYDRATE AND ITS MODE OF ADMINISTRATION.—Dr. J. C. Ogilvie Will quotes the minutes of various cases of neuralgic affections, one of the passage of a renal calculus, two of whooping-cough, one of cough following pleurisy, and two of cough in phthisis, in which the croton chloral was administered in small doses, and with the happiest results. He employs a syrup containing two grains of croton chloral to a drachm of a mixture of glycerine and syrup of orange-flowers, colored by adding a very minute quantity of tincture of cochineal. In this mixture the taste of the chloral, he says, is entirely concealed, and the preparation, moreover, is permanent, which undoubtedly is of great advantage.

In adults suffering from neuralgia he uses two or three grains of the chloral at varying intervals, according to the severity of the pain, the largest quantity he has been obliged to use before relief was obtained, being fourteen grains in two hours.

In the case of whooping-cough which he reports, he used fifteen or twenty minim doses of the above mixture at bedtime, with good results, the fits of coughing becoming much less severe in character, though about the same in frequency. The ages of these patients were respectively four and five years. In the other cases, all adults, of cough in phthisis and after pleurisy, the doses varied from one to two drachms of the syrup, but were always followed by relief.

Dr. Will, judging from his own experience, endorses Liebreich's statement, "that croton chloral rapidly produces slumber similarly to ordinary chloral, but

without its use being followed, as in the case of the latter, by lowering of the pulse and respiration."—*The Medical Press and Circular*, May 12th, 1875.

LEAD POISONING IN LEAD WORKERS.—Dr. Ramskill has given a *résumé* of sixty cases of poisoning among white-lead workers, who had been under treatment in the wards of the London Hospital, within the past two years. Of the sixty, thirty-three were males and twenty-seven females. Of the males, the majority were between twenty and thirty years of age, only seven being over forty. The fact that the largest number who were poisoned were under thirty years of age would seem to indicate, he thinks, that the men are unable to work for a long period without suffering. Of the twenty-seven females, three were under twenty, three over forty, and of the remainder, nine were between twenty and thirty, and eleven between thirty and forty. From this it would seem, at first sight, that the women were able to continue at the work longer than the men, but he found, on inquiry, that the latter commenced the work earlier in life, and therefore were younger when attacked.

The early or late appearance of poisoning varied with their special employments, the most injurious occupation seeming to be attending to the drying and carrying of the newly dried material to the work-house.

This newly dried white-lead is powdery and easily shaken about, and so may enter the system by the mouth, in respiration, or by becoming intimately mixed with the clothing and infecting the body through contact with the skin.

The treatment at first consisted of removal of the patient from the source of the disease, rest, and in some cases the administration of quinine and sulphuric acid; in others, sulphate of magnesia followed by iodide of potassium. Two of the sixty patients died, both being young women and sisters, and in each epileptiform convulsions were features of the case. In one, lead was found in the brain.—*British Medical Journal*, May 8, 1875.

EVIDENCES THAT PREGNANCY HAS TAKEN PLACE.—Dr. Wachs declares that the longer the time that has elapsed since the labor, the more difficult will it be to determine that it ever took place. Lax, hanging breasts may be due to various other causes, and are of no diagnostic value. Nor do prominence of the nipple and development of the areolar glands furnish positive evidence, as they may depend upon other pathological processes, especially in the uterus. Pigmentation of the areola never disappears completely after the first pregnancy, but if there have been pregnancies preceding the one suspected, it would not be possible to make sure of the degree of fading. A rose-red color of the nipple and areola argue against previous pregnancy. The presence of milk in the breast points to pregnancy, the absence of it does not disprove that condition. The traces of pregnancy on the skin of the abdomen may not be present if an early abortion has occurred, so that the integuments were never unduly distended, and on the other hand ascites, ovarian dropsy, or uterine fibroids may cause these striæ. After the distention of pregnancy the skin of the abdomen loses its elasticity, so that it may be taken up in folds; but if the puerperal woman keeps the horizontal position for the regular nine days, and avoids exertion, this elasticity is largely recovered. Such precautions are not likely to be observed when the fact of labor has to be concealed, and the skin remains lax, so that the hand can easily be pressed against the lumbar vertebra, which the author regards

as a very important indication. There has probably been pregnancy when there is a lacerated perineum or ruptured frenulum, though the latter may possibly remain intact in spite of labor. The presence of an intact hymen argues against a previous labor, and even an abortion could only have occurred in the very earliest months. A diminution and laxity of the folds of the vaginal wall point to pregnancy. Further decided indications are found in lacerations of the margin of the os uteri, a cylindrical portio-vaginalis and a gaping os, although the author declares that long-continued abstinence from sexual gratification may do away with these latter changes. He admits that there are many cases where it would be impossible to express a positive opinion.—*Vierteljahrscr. f. gerichtl. Med.—Rundschau*, April 12, 1875.

REST IN NERVOUS DISEASE.—Under this heading, Dr. S. Weir Mitchell contributes an article that forms the fourth number of Dr. Seguin's Series of American Clinical Lectures. In order to get the full benefit of this particular treatment of the disease, it is often necessary to put the patient to bed, and prevent, as far as possible, all voluntary effort. The effect is much the same as when a fractured limb is placed in splints. The muscles become flabby, the vessels lose their tone; the skin suffers in its nutrition, the joints become stiff, and for a time the function of the part is lost until the effects of the rest are counteracted by stimulated activity. But when the whole body is permitted thus to remain inactive, the effects are more general and serious. The appetite is lessened, the digestion may suffer, the bowels become constipated, the circulation enfeebled. The temperature falls, and the pulse becomes "a third slower." Another consequence to which allusion is made as a serious consideration is that this inactivity at first enforced may, in the end, become a permanent condition. This is especially true of women, who are very apt to become bedridden under these circumstances.

The first class of cases mentioned, for which the treatment by mechanical rest is advised, consists of those in which pain is the most prominent symptom—the neuralgias. The fact is pointed out that when a nervous centre is in a morbidly irritable state, the impressions produced by normal functional activity become converted into sensations of pain.

The writer mentions a rare form of writer's cramp, which is attended with pain, and which may always be relieved by rest. Next, a variety of affections of the central nervous system is mentioned, in which this treatment is regarded as exceedingly important. A disorder peculiar to women is described, which is characterized by a condition of defective nutrition, in which a painful sense of fatigue is the most prominent symptom. Besides, the patient has a low temperature, the pulse is usually accelerated, more or less anaemia is present, with an increased proportion of white blood-corporcules. Every attempt at exertion, whether mental or physical, immediately occasions an extreme feeling of weariness, so that ultimately the power of exertion is almost entirely lost. The treatment consisted in keeping the patient in bed, and prohibition of the slightest exertion. At first the patient was not even allowed to turn herself in bed, and was fed chiefly by the rectum. To counteract the effect of the loss of normal muscular exercise upon the circulation, etc., recourse was had to massage and faradism of the muscles.

Allusion is also made to the use of rest in the early stages of spinal congestion, meningitis and chronic myelitis, but especially in locomotor ataxia. Mitchell was first led to adopt this treatment in the latter disease, in consequence of seeing several perfect

recoveries in the painful stage of the affection, follow fracture of a limb, compelling the patient to a season of quiet in bed.

EPIDEMIC THORACIC CATARRH.—This name Finsen has given to an epidemic thoracic affection peculiar to arctic regions, and especially Iceland. Of the 155 cases observed by him in the latter country, 72 were of the catarrhal form, 42 pneumonic, and 41 pleuritic. Two such epidemics were observed: the first lasting from the fall of 1859 to the end of 1860, spreading from the eastern portion of the northern district over the whole country, and terminating in the eastern district. The second, on the contrary, commenced in the eastern district, and spread in a westerly direction over the entire country, terminating in the winter of 1863. These epidemics were peculiar in a pathological regard, not only because of the marked contagious nature of the catarrh, but also because of the remarkable fact, that one and the same epidemic consisted of such varied forms of disease as catarrh, pneumonia, and pleurisy, and that the last two inflammatory diseases should be contagious. He thinks that there could be no suspicion of a mistake in the diagnosis, for similar epidemics also occur in Greenland.

The "snuffles" epidemic of Greenland also consists of catarrh, pneumonia, and pleurisy, but it occurs regularly every year at the same season, and spreads over the country with a strong developed contagiousness, passing from north to south, and later in the year with a retrograde movement, from south to north. It is of a more dangerous character, however, than the Iceland epidemic—a very considerable portion of the cases terminating fatally.

Epidemics of influenza are of more frequent occurrence, and from their wide extent play a more important rôle than in Europe. The author passed through three such, which did not present any peculiarity other than their great intensity. In one of them 2.37 per cent. of the population of his district perished. The greatest proportion of fatal cases occur in early childhood, before the fifth year, and are also frequent after the fiftieth; very few patients between five and thirty die of the disease. When the disease once commences it travels in every direction, without regard to wind or weather, with such rapidity as to spread through the whole island in less than two weeks. It lasts between six and eight weeks, and in this time has, with few exceptions, attacked the entire population.—*Hospitals-tidende*, Dec. 1874.

CHARCOT ON THE RELIEF OF HYSTERICAL SEIZURES BY COMPRESSION OF THE OVARIES.—According to Charcot most hysterical seizures are preceded by an aura starting from one or both of the ovaries, and he finds that pressure on the organ indicated causes immediate arrest of the seizure. He illustrated this action upon a patient in the Salpêtrière affected with hysterical epilepsy. The seizure recurred, however, the moment the pressure was taken off. In order to keep up the pressure for a longer time than would be possible with the unaided hands he recommends an apparatus like a tourniquet. The pressure is to be made in the situation and direction requisite in compressing the iliac artery, and, in fact, this vessel will be felt pulsating under the finger.—*Gaz. Méd. de Paris*, Nov. 5, 1875.

A NEW METHOD OF SHOWING WAXY CHANGES IN THE TISSUES.—At a recent meeting of the Société de Biologie in Paris, M. Cornil exhibited a number of preparations in which he demonstrated the presence of waxy degenerations by means of the *Violet de Paris*, or the violet of methylaniline. The affected elements assumed a bright red color, while the others were colored blue.—*Gaz. Hebdom.*, May 14, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WJL. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, June 19, 1875.

DIPHThERIA IN NEW YORK.

OPINIONS have frequently been expressed in medical circles that the prevalence of diphtheria in this city has been a good deal over-estimated by the public, and that the number of fatal cases for the past six or eight months has not been much larger than for similar periods of other years. This view, however, is not sustained by the mortality tables published by the Board of Health. We find, if we consult them, that for thirty-two weeks, dating from and including the week ending the 26th of September, 1874, to and inclusive of the week ending the 1st of May, 1875, the reported mortality from diphtheria has been very much greater than during a like period in 1873-4, and more than four times as great as the average mortality during a like period for the past five years. There is another point that attracts attention, which is that for the past two years the mortality from diphtheria has been remarkably high throughout each entire year. During 1874 the lowest weekly mortality was 14, to which it fell twice, once for the week ending March 28th, and once for the week ending June 13th, the lowest average weekly mortality for the past five years being 5. In September it had reached 22, and then it began to ascend rapidly, and was 42 in October. In November it had reached 65, but fell off again to 41 in December, again rising until 73 was reached for the week ending January 16th, 1875. From this point it again fell off, though it still maintained a high average during February and the first part of March, declining in the latter part of this month to 35. At the end of April the mortality was still 44, as opposed to 24 for the corresponding week of last year, and 10.4 for the average of corresponding weeks for the past five years.

The principal errors in these statistics are due, it is claimed, to the lack of common agreement between physicians as to the application of the terms diphtheria and croup, and the confounding of scarlet fever in

some of its forms with the former. As an instance of this circumstance it is said that in England, when the name diphtheria came into usage, many less cases of membranous croup were reported, though at the same time there was no reason to suppose that the disease itself, as described in the text-books, was any less frequent. As far as this point is concerned it cannot be shown that the recent discussions on the identity or non-identity of diphtheria and membranous croup have affected the statistics adversely for membranous croup. On the contrary, the number of reported deaths from membranous croup has been even larger than usual. Taking the statistics of the thirty-two weeks already spoken of we see that the number of deaths is reported at 531, as compared with 512 for a corresponding term in 1873-4, and 435.2 for the corresponding term averaged for the past five years.

From this record it would appear that the excessive mortality from diphtheria was not due to the inclusion of croup cases among them. With scarlet fever this is perhaps different, for we find that during the thirty-two weeks mentioned the mortality was 409, as contrasted with 749 for the corresponding period in 1873-4, and 623.8 as the average for corresponding periods in the last five years. Here, then, the mortality was considerably less than the average, and notably less than for the preceding year, and it may well be that abortive cases of scarlet fever were assigned to the diphtheria list. Still, even if this allowance be made, and it be assumed that scarlet fever had as many victims during this season as during the preceding one, we still find that the sum of this number added to the reported deaths from membranous croup gives only a total of 1,280, as compared with 2,461, the grand total of the actually reported deaths from the three diseases, thus leaving a balance of 1,181 in favor of diphtheria, against an actually reported sum of 1,521, and a general average mortality for the same period for five years of 393.6. So that, even if all these deductions be made, it would appear that the actual number of deaths from diphtheria has been about three times the average number. There are some other interesting statistics that may be gleaned from these reports. During this period of thirty-two weeks the reported cases of membranous croup fell as low as 4 per week, and never exceeded 29, though they reached that figure twice, and then diphtheria was very high—at 50 and 73. There does not seem to be any constant relation, however, in the rise and fall of the two diseases.

Scarlet fever, as we have before observed, was less frequently reported as a cause of death. The lowest weekly mortality was 3, when diphtheria was 48, and the highest was 20, which was reached on two occasions. As with membranous croup, there was no constant ratio in the mortality of the two diseases.

When we take the sum of the deaths from these three diseases during these thirty-two weeks, we find that there is only an excess of 113 over the same period in 1873-4, though nearly a thousand more than

in the same weeks averaged for the past five years. These facts point unmistakably to a rapid increase in these diseases which truly justifies solicitude on the part of physicians and the public.

What are the noticeable facts in regard to its locality in New York? One thing is pretty certain, viz., that it has prevailed most extensively among the poorer classes and in those particular parts where attention to general sanitary measures has been least observed. This is a valuable point, and if we could only determine whether the proportional number of those attacked, or even of the fatal cases, were greater among the poor, and in association with deficiency in attention to sanitary matters, we should be in the possession of a valuable item of information. Unfortunately this is a problem that we have no means of solving. Where a given area of the city furnishes the largest number of deaths from diphtheria, there also are generally the largest number of families living together, and we should naturally expect, *ceteris paribus*, that at these points there would be the greatest mortality from any disease. As yet we have no means of knowing the actual number of the population to a given area, and therefore can reach no definite results in this direction.

This much may be said, that certain localities appear to favor the disease, whether this is accidental merely or not, for the disease has usually selected particular points in each epidemic, and, starting from them, has moved in a definite direction. The east and west sides of the city have been particularly visited. A glance at the excellent maps which have been devised by the Sanitary Superintendent of the city to illustrate this subject, shows that on the west side especially there has been a special focus of trouble in the district lying between Thirty-ninth and Forty-second Streets, and between Ninth Avenue and the river. This portion of the city is one of the principal centres for slaughter-houses, both for hogs and bullocks, and much of the area is given up to cattle-pens and receiving-yards, all of which are unavoidably offensive in the way the slaughtering business is conducted at present. Many of the population live in cabins on the rocks, where, of course, there is no proper escape for their waste, while about them is a great deal of new-made land. The disease seemed to develop a certain amount of intensity here, and then began to move slowly and somewhat irregularly downwards. On the east side the condition was somewhat similar, except that the focus was not so clearly marked, and its course downwards towards the lower part of the city was even more irregular than on the west side. The central districts of the city have only been invaded at isolated points. There is far less regularity, however, in the spread of diphtheria than of such strongly contagious diseases as small-pox. In the one case, there are comparatively few cases in a single block, and they are often pretty uniformly scattered over a large extent, while in small-pox the cases are often so crowded together that a dozen or more may occur in a single

block within a very short time, while the scattered cases will be exceedingly few.

It may safely be said that diphtheria does not appear to have any connection with the distribution of the old water-courses of the city, but also that a large number of cases have originated without any suspicion of contact with the diseased matter in any form, while in some of these instances sanitary defects of a very serious kind have been found in the dwellings, making it highly probable that noxious emanations and the like have produced the disease. It may possibly be due to the foul emanations from slaughter-houses and other nuisances, or it may arise from some accident or neglect in one's own dwelling, where it was supposed that every sanitary regulation was vigorously enforced. Such might be the explanation of the following interesting case: A prominent physician of this city was suddenly taken ill with diphtheria, and was confined to his room for five days. On recovering, and making a careful inspection of his premises, he found that in some unknown way the soil-pipe carrying the waste from the adjoining houses had burst, letting in upon his cellar floor a collection of rotteness and filth that was of the most disgusting kind. It is difficult always to be able to make a careful examination of the premises in this way, but it seems probable that if each case of diphtheria were carefully investigated, a large number of the so-called idiopathic cases might be traced to some such source. Many similar instances probably occur to the mind of most practitioners, and there seems to be no reason why such influences as these described should not in many cases be causes of diphtheria, just as they may often produce typhoid fever, puerperal fever, and erysipelas—an opinion that is beginning to be very generally held.

DR. J. M. CORNELISON.—At a special meeting of the District Medical Society for the County of Hudson, N. J., held in the rooms of the Young Men's Christian Association, on the 27th of May, the following resolutions were adopted:

Whereas, in the ripeness of age our friend and colleague Dr. J. M. Cornelison, first President of our District Society, and one of its charter members, has been summoned from time to eternity, a shock of wheat ready for the sickle; we, prompted by deep sympathy for those who were dear to him by ties of consanguinity, as well as high regard for the memory of the departed, have met together as members of a common profession, to give expression to our feelings upon this sad occasion.

Resolved, That in the death of our esteemed friend, whose urbanity and kindness of heart had endeared him to us all, we recognize the hand of Providence, and the march of time; and as we bow in submission to His will, we cannot but give expression to the sadness that fills our hearts at this dispensation.

Resolved, That this mournful event has taken from our midst one whose honorable and generous character had won our esteem and the respect of the whole community.

Resolved, That a copy of these resolutions be published in the daily papers, MEDICAL RECORD, and *Medical and Surgical Reporter*.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.*

Stated Meeting, May 20, 1875.

DR. S. S. PURPLE, President, in the Chair.

First Meeting of the Academy at its own Home.

AFTER the reading of the minutes of the previous stated meeting, the PRESIDENT, with a feeling of sincere pleasure and congratulation, formally welcomed his fellow members to their own home. As men reckon time, a generation has not yet passed since this institution sprang into existence, and from its very beginning up to this auspicious hour, it has been its aim and purpose to keep pace with the wants of an advancing profession. It had been deemed proper that the deed of the building, and other papers held in trust by the Committee of Ways and Means, should be formally transferred by its chairman to the trustees of the Academy, by giving an account of their stewardship, and accompanying the same with such recommendations as they in their wisdom may deem expedient.

Report of the Committee of Ways and Means, and formal transfer of Papers to the President of the Academy.

DR. ANDERSON, Chairman of the Committee, then presented the report, and remarked that it afforded him great pleasure to present these papers as evidence of the completion of the work required of this Committee, after which he gave a brief review of the early associations, scenes, and expressions which gave birth to this institution, and of the work which had culminated in a reunion in its own home. In the early history of the Academy, it was contemplated to establish a hall, a library, and a museum, independent of any hospital or other building, for the use of the profession. The Fellows of the Academy now numbered over three hundred and fifty; and all should arise to the work yet necessary to be sure of all they would realize in what is embraced in the full meaning of the word *home*. They should not now rest satisfied, but should at once take the initiatory steps for securing a site upon which a building of sufficient size could be placed—to furnish room for a hall, a library, and museum, which shall make it a great medical centre, both attractive and scientific.

The President received the papers with appropriate remarks, in behalf of the Academy and Board of Trustees, and Dr. Oliver White, Chairman of the Board of Trustees, accepted the custody of the papers which now became the property of the Academy. In assuming this trust he expressed, on behalf of his associates and himself, their acknowledgment of satisfaction for the great work done by the Committee of Ways and Means, and that it should be their constant effort to discharge the duty, in caring for their trust which the charter of the Academy contemplates. He expressed his earnest desire that the Committee of Ways and Means might be continued until the happy day shall arrive when the debt now upon the home will be completely wiped out. He then offered a resolution, tendering the thanks of the Academy to that Committee for the faithful manner in which they had performed their duties, which was unanimously adopted.

* By some oversight the appearance of this report has been delayed until this time. Inasmuch as it involves a matter of historical interest we have concluded to publish it, notwithstanding.

PORTRAIT OF DR. JOHN STEARNS.

The SECRETARY read a letter from the family of Dr. Stearns, which had been accompanied by a portrait of their father as a donation to the Academy.

DR. JOEL FOSTER offered a resolution, tendering the thanks of the Academy for the portrait presented by the family of Dr. Stearns.

DR. PURPLE gave a brief biographical sketch of Dr. Stearns, who was the first President of the Academy.

Dr. Stearns was born in Willoughby, Mass., in 1770. He attended lectures in the University of Pennsylvania, in 1792-3, and in 1793 took up his residence in Saratoga County, N. Y. Dr. Beck gives Dr. Stearns the credit of rescuing ergot from the hands of empiricism, and making it a recognized article of the materia medica. He came to New York in 1819, and died in the year 1848, of pyæmia, from a wound accidentally received in the prosecution of professional duty. The resolution of Dr. Foster was unanimously adopted.

DR. HUBBARD in the chair, DR. WILLARD PARKER offered a resolution of thanks to Dr. Purple for the sketch of the life of Dr. Stearns. Adopted.

PORTRAIT OF DR. JOSEPH MATHER SMITH.

The Secretary read a letter from Dr. Gouverneur M. Smith, through which the portrait of his father was presented to the Academy.

DR. WILLARD PARKER, as a colleague of Dr. Smith, offered, with appropriate remarks, a resolution tendering the thanks of the Academy for the donation.

DR. ELISHA HARRIS seconded the resolution with remarks highly eulogistic of the life and character of Professor Smith, as shown by his sympathy for his fellow-men, for his medical brethren, and his labors for the development of scientific truth. Upon his entire nature the signet of true nobility was set.

The resolution was unanimously adopted.

PORTRAIT OF DR. GILBERT SMITH.

The Secretary read a letter from Mr. Charles D. Smith, which had been accompanied by a portrait of his father, one of the founders of the Academy.

DR. J. G. ADAMS referred to the high reputation and integrity of Dr. Smith, and spoke of one trait in his character which was worthy of special mention, and that was his deep interest in the welfare of the younger members of the profession. At the close of his remarks he offered a resolution tendering the thanks of the Academy for the donation, which was unanimously adopted.

PORTRAIT OF DR. GALEN CARTER.

The Secretary read a letter from the family of Dr. Carter, accompanying the portrait presented to the Academy, and DR. GURDON BUCK offered a resolution tendering the thanks of the Academy for the portrait received.

DR. A. C. POST seconded the resolution with a few choice words, in which he paid a high tribute of respect to Dr. Carter, as a man with a professional and social relation remarkable for his high sense of honor and unexceptionable integrity.

The resolution was unanimously adopted.

A letter from Dr. John G. Adams, Corresponding Secretary of the Academy, was then read, through which he presented to the Academy bronze busts of two of the ancient masters in medicine, Æsculapius and Hippocrates.

DR. GARRISH moved that the thanks of the Academy be tendered to Dr. Adams for his valuable gift, which was unanimously adopted.

At this point the PRESIDENT remarked it was possible that some of the members of the Academy had

not been called upon by the Committee of Ways and Means, and if so, all may feel it to be their privilege to contribute whatever they shall feel able, which will be gratefully accepted.

DR. ANDERSON remarked that one hundred and twenty-five Fellows had subscribed, and one hundred and fourteen of that number had paid, and announced that the Treasurer could be found at 113 University Place, ready to receive any subscription which the Fellows of the Academy, or any one else, may be pleased to make.

The President then called upon Dr. Detmold, who remarked that he belonged to a class of men who were gradually disappearing, and will soon become entirely extinct. He hoped no one would think him presumptuous in making this statement, for of the original members and founders of the Academy, all except twenty-five or six had been removed by death. He well remembered when the meetings of the Academy were held in a dingy room above a coal-yard in Wooster Street, and he might also state that the discussions of those days bore to the discussions of the present day about the same relationship that the dingy rooms over the old coal-yard bears to the elegant apartments in which they were assembled. The Academy had improved in many respects.

The Doctor then indulged in some reminiscences relative to the origin of the idea of securing a building for the Academy, and said in conclusion that he regarded this hall, elegant as it is, in the same light as he formerly regarded that dingy old hall in Wooster Street. He regarded that hall as simply a starting point, and he now looked upon this elegant hall in no other light than a starting-point—a new departure, if you choose; for he felt sure that very many of the Fellows now present would be able to look back to this evening and upon this hall with the same pride with which he looked back upon the old coal-yard hall. He could see no reason why the Academy should not have, and that within a reasonably brief period of time, an appropriate fire-proof building with all the necessary appurtenances, which should be worthy of the profession and worthy of the Capital of the New World.

The Secretary then read a letter from Dr. Austin Flint, in which he expressed his great disappointment in not being able to be present, and desired the Academy to accept the assurance that he should be at the meeting in spirit, although unavoidably absent in person. The circumstances which prevented his attendance were beyond his control, and he claimed the privilege of imposing a fine upon himself for his absence, and enclosed the same.

DR. WILLARD PARKER being called upon, remarked that he regarded this institution as the centre of the medical profession in this city. It has been said by some that the Academy of Medicine was not necessary, because there were now so many regularly organized medical societies in existence among us; but if we look at this matter in one way, we shall find that the Academy is the centre and parent of the whole. The Academy is not a specialty, but associates in itself all specialties. This Association is to be the great organizer and controller of the profession of this city. The associations outside are the working departments, in a certain way, and each in its special department is exceedingly effective and useful. He spoke of the labors already performed by this Society, and that it is now in the way of accomplishing more than it has at any other time, for he regarded the generosity of the medical profession as transcending that of any other body of men in the world. He expressed the warm desire

that every member of the Academy should give according to his ability, whether a small or a large amount, and thus have a share in this institution. Let no one hesitate to contribute because he cannot pay a large sum, for it is not always the large amount that carries with it the true value. In the matter of securing a still larger and more commodious building, there is no need of great haste. Some of the greatest and most magnificent structures in the world have been completed only by many years of toil, and the same determined action which has secured those should characterize the efforts put forth by this Academy of Medicine.

DR. ANDERSON announced that it was the intention to secure a photograph of the old hall over the coal-yard.

At the conclusion of the ceremonies the members repaired to the basement, where a bountiful repast awaited them.

Stated Meeting, June 3d, 1875.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

RUPTURE OF THE PERINEUM—ITS PREVENTION AND CURATIVE TREATMENT.

DR. E. NOEGGERATH read a paper upon the above subject, and had been led to do so from the fact that, notwithstanding the thorough discussion it has received at the hands of authors, and comes so frequently under the observation of the physician, he had become convinced, from late discussions in the New York Obstetrical Society, that it is worth while to go over the ground again. As the matter now stands it is a difficult question for the young practitioner to decide what he is to do when he meets with a lacerated perineum.

The remarks of the writer were confined exclusively to practical points in connection with means of preventing the occurrence of the accident, and of curing the injury done when it has taken place. The only reliable method of determining whether rupture of the perineum has taken place or not is by inspecting the parts. The term should include only those lacerations which reach near to or even involve the sphincter ani muscle.

To guard against the occurrence of the accident it is necessary to be acquainted with the circumstances which may favor it. These circumstances were considered under the head of presentation first, and the fourth position was regarded as the one in which rupture is most apt to occur. Smaller heads are more commonly accompanied by rupture than larger ones, and this is not strange.

The two principal conditions for guarding against the accident are:

1. Slow and gradual dilatation.
2. Equable distribution of pressure upon the periphery of the vaginal aperture.

There is a condition of the tissues characterized by a peculiar bluish color, indicating that they are unhealthy, which renders it impossible with the greatest care to prevent rupture from taking place. With regard to forceps being a prolific cause of rupture of the perineum, he had become convinced by his own experience that if rupture does occur while using the instrument, its location does *not* coincide with the position of the lower edge of the blade. Exceptions to this rule do occur, but they are only exceptions. There is no doubt about the fact that the proportion of ruptures is larger when forceps are used, but the reason consists in the additional fact, first, that the blades of most instruments are too wide, and second, for obvious reasons, instrumental deliveries are terminated too rapid-

ly, and the advice to extract the head in the interval of two pains is not generally observed. In faulty positions of the head the forceps may be an efficient means for saving the perineum from rupture. To prevent too rapid expulsion of the head chloroform is an efficient agent.

Among the means mentioned for the prevention of rupture were incisions upon each side from the vulva towards the ischii, and made with a bistoury or scissors.

A large number of ruptures of the perineum heal up without any interference in the way of operative procedure, but the parts are not thus reinstated to their natural condition.

The only rational method of treatment is to apply sutures as soon as possible after delivery, and the reason why the early operation has been abandoned for some time is because of want of knowledge of those conditions which are requisite to insure success. From various statistics it was claimed that success is obtained in about 75 in 100 cases, and some physicians cure every case upon which they perform the operation. The adoption of the immediate operation does not exclude contraindications, but a low condition of vitality is the only one to be taken into consideration in this connection.

The extent of the rupture itself should not be accounted as an indication for delaying the operation. Another contraindication which has been urged is the danger of puerperal fever induced by the spread of poisonous elements from the canal of the sutures, especially at the time of their removal. If this was the case, it should be especially noted in New York, where this disease is so prevalent, but it has been determined that those patients whose perineal ruptures have been united immediately after the accident, stand the best chance in an epidemic of child-bed fever, and it is reasonable to expect that the closing up of a torn surface should diminish the chances of absorption from such surfaces. The method is in every case, where rupture is anticipated, to give chloroform when the head is impinging upon the perineum, in order to have the operation performed before the patient has returned to consciousness, or to spare the patient pain when the incisions are decided to be made. Except the paring of the edges, the method of operation is the same as when the operation is performed upon an old rupture.

The paper being open for discussion, PROF. BARKER remarked that he did not propose to go over the entire ground connected with the subject, for he had already discussed it with considerable fulness in his work upon puerperal diseases, consequently his views were quite well known to the members present. In the first place, however, let us look at some of the causes which pertain to ruptured perineum. We have anatomical causes, various physiological causes, causes due to reflex phenomena, causes due to the mechanism of labor, causes due to instrumental delivery, and *each one of these* is to be met by certain special means for the purpose of preventing this accident. Among the anatomical causes mentioned is the straight sacrum, difference in direction of the vulvar opening—in some being almost parallel with the axis of the abdomen, in others parallel with the axis of the vagina—and difference in size of the vulvar opening.

The condition of the tissues referred to by the author of the paper, characterized by a bluish color, etc., he did not remember to have observed. There is, however, in some perineæ, a deposit of a considerable proportion of adipose tissue which predisposes to rupture. Long-continued pressure of the head against the perineum destroys its original power to yield and

be dilated without rupture, and in such cases the forceps become a most useful means of prevention. There are also certain physiological conditions which predispose to rupture of the perineum. Certain cases of labor are accompanied by a nervous condition which leads the woman to make violent efforts at expulsion, and the head may be driven through before proper dilatation can take place. It is a matter of observation that this class of patients are very apt to have rupture take place.

There are certain mechanical causes; for example, such a position of the head as gives rise to large dilatation without gradual dilatation. In certain of these cases it is almost impossible to prevent rupture. The forceps may be a mechanical cause of rupture, and they may be a most efficient means of preventing rupture, especially in that class of cases where injury to the tissues may result from long-continued pressure upon the perineum.

The danger in the use of forceps arises from the fact that they are used as instruments of direct traction, instead of instruments to complete a normal process, a physiological delivery of the head. While speaking of the prevention of rupture, he mentioned a method of procedure which was resorted to in a case of right occipito-posterior position that he had not seen mentioned in any of the text-books. An attempt was first made through the vagina to rotate the occiput into the anterior position, but it was found impossible, for the occiput would rotate back into the hollow of the sacrum at once when the hand was removed. The woman was then carried profoundly under the influence of chloroform, the left hand introduced, and with a good deal of effort he succeeded in pushing the head up out of the pelvic cavity; and then with the right hand upon the abdomen rotation of the trunk was effected, so that he brought the occiput around, and then he pressed the head under the symphysis pubis, and soon completed delivery without rupture and with a live child. He was quite sure that by this operation he saved the perineum, and also the life of the child.

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting, May 21st, 1875.

DR. LORING, VICE-PRESIDENT, in the chair.

Ankylosis of the Temporo-Maxillary Articulation of long standing.

DR. D. H. GOODWILLIE presented a patient, together with the history and treatment of the case, in which the above condition had been present. The patient, a girl aged ten years, who was sent to him by Dr. Sayre, fell over the bannisters when she was five years old, and, it was supposed, received a fracture of the condyle of the lower maxilla through its neck upon the right side. Ankylosis followed. When the patient was seen by the doctor, in October, 1874, there was ankylosis, atrophy of the depressors, and contraction of the levator muscles. The treatment had consisted in the use of electricity to assist in restoring vitality to the muscles, together with manipulations while the patient was under the influence of nitrous oxide gas. After some progress had been made, a special apparatus was employed for making traction upon the contracted tissues, assisted somewhat by sections of tissues upon the inside of the mouth, and now, after about seven months of unremitting effort, the mouth could be

opened nearly an inch, and motion was very free. The girl was able to masticate with the molar teeth, but was not able to close the mouth so as to bring the incisors in contact. The case was an interesting illustration of what can be accomplished by perseverance in treatment. The nitrous oxide had been exhibited nearly one hundred times as a rule, every other day—and the doctor was of the opinion that he would have failed in obtaining relief in this case had it not been for the assistance afforded by this agent.

Dr. Post remarked that the success obtained in Dr. Goodwillie's case illustrated a principle, namely: that cicatricial contractions can be overcome, but not without long-continued effort and perseverance. He had for himself proven conclusively that the disposition to contraction in cicatricial tissue can be so overcome that it will not return. It requires great patience to accomplish this, and sometimes the assistance afforded by tenotomy and myotomy becomes necessary. By passive motion, exercise, encouraging the muscles to act, and stretching the tissues, perhaps cutting, the difficulty can be gradually overcome. This principle is illustrated in almost every form of cicatricial contraction. It is well illustrated in stricture of the urethra, where by stretching the parts with very large instruments, occasionally using the knife and following it by excessive stretching, perhaps sufficient to permit the introduction of No. 35 or 40 of the French scale, the disposition to contract is ultimately overcome, and the urethra remains free for life.

A vote of thanks was given for the paper, and the Association adjourned.

Correspondence.

MEDICAL ADVERTISING.

TO THE EDITOR OF MEDICAL RECORD.

DEAR SIR:—In THE RECORD for May 29th I propounded a question for your consideration, whether the publication of the "Protest" in a daily paper was not in violation of the "Code of Ethics." You remark: "We cannot believe that the publication was sanctioned by the gentlemen signing the document, but that it was the result of a mistaken policy and short-sighted enthusiasm of some one of the interested parties." You add: "Such documents are always out of place in a secular paper, and always tend to lower the profession in the estimation of the public." In this opinion, Mr. Editor, I most heartily concur. I never, for a moment, thought of charging upon the many honorable signers of this "Protest" the imputation of desiring to see their names or titles published in a daily paper. I know that it was done (as regards the majority of them) without their consent or knowledge. The charge of having violated the Code of Ethics rests, therefore, upon the parties who furnished a copy of the document to *The Tribune*. I do not presume to judge of motives, but of one thing I am very sure, they did not thereby intend to benefit the institution in the estimation of the contributors or general public.

I beg leave to submit for the perusal of these "inexperienced parties" the following extracts from our "Code of Ethics;":

"Advertisements indicating locations and residence are the utmost limits of self-announcement consistent with professional dignity. All referring to special branches, as extra inducements to patronage, should be

deemed a violation of the code of medical ethics."—*Transactions State Medical Society, 1865.*

"It is derogatory to the dignity of the profession to resort to public advertisements."

"As peculiar reserve must be maintained by physicians towards the public in regard to professional matters, and as there exists numerous points in medical ethics and etiquette through which the feelings of medical men may be painfully assailed in their intercourse with each other, and which cannot be understood or appreciated by general society, neither the subject matter of such differences, nor the adjudication of the arbitrators, should be made public, as publicity, in a case of this nature may be personally injurious to the individuals concerned, and can hardly fail to bring discredit on the faculty."—*Code of Medical Ethics of American Medical Association.*

Mr. Editor, the Code of Ethics, adopted by all honorable members of our profession, has answered my question.

Should your courtesy accord me the requisite space I propose, in another letter, to show that the recent action of the managers was not only justifiable (and therefore right), but that there are in abundance precedents of similar character to warrant their procedure.

"MEDICUS."

SPECTRAL ANALYSIS.

In order to avoid any further discussion in regard to the questions connected with the subject of spectral analysis, which have from time to time claimed the attention of our readers, we have undertaken to present the facts of the case from an impartial standpoint. The main point in dispute between Drs. Waterman and Piffard has reference to the charge of misquotation on pages 247 and 367, and as all the facts connected with such a charge are matters of record, there is no better way of appreciating the merits of the case than by a careful comparison of the statements of each of the gentlemen. This we shall undertake to do by arranging the questions and answers in opposite columns.

DR. WATERMAN SAYS:

I.—Oct. 15, 1874.—"Professor Draper, of this city, whose merits in this direction are gratefully acknowledged, has given to us a map containing a great number of sun-lines, invisible under ordinary circumstances, but which can be made visible under certain favorable conditions; these additional lines are made evident at both the red and violet part of the spectrum." The fact is, Draper's photograph shows no lines in red, orange, yellow, or green, for reasons known to every photographer and physicist."

II.—Vol. X., page 84.—"In my lecture I stated that Professor Draper has given us a map containing a great number of sun-lines, invisible under ordinary circumstances; these lines are made evidently at the red and violet part of the spectrum."

III.—Page 213.—2. "These additional lines are made evident (not evidently, as Dr. P. has it) at both the red and violet part of the spectrum, making it of course longer than usual." "These additional lines are made evident (not 'evidently!') at both the red and violet part of the spectrum."

IV.—May 22, 1875.—"In my

DR. PIFFARD SAYS:

I.—Nov. 16, 1874.—"A similar error is committed in reference to Prof. Henry Draper, who 'has given us a map containing a great number of sun-lines, invisible under ordinary circumstances; these additional lines are made evident at both the red and violet part of the spectrum.' The fact is, Draper's photograph shows no lines in red, orange, yellow, or green, for reasons known to every photographer and physicist."

II.—Vol. X., page 139.—"Dr. W., in his reply, re-asserts that some of the lines in Draper's map 'are made, evidently, at the red and violet part of the spectrum.' (I italicize the word red.) The following, I think, will be sufficient evidence of Dr. Waterman's error." [Then follows Dr. Draper's letter, in which he (Dr. D.) says that the red portion is not included in his (Dr. D.'s) map.]

III.—Page 217.—"In his letter of March 20 (page 213) Dr. W. denies using the word 'evidently' in a certain connection. If the reader will turn to Dr. W.'s first reply to me, *RECORD*, Jan. 30, p. 84, third paragraph, he will find this word exactly as I quoted it in mine of Feb. 20."

IV.—[Comparison of the lines in

original lecture, see RECORD, October 15, 1875, which Dr. P. undertook to criticise, I stated "that sun-lines invisible under ordinary circumstances can be made evident at both the red and violet parts of the spectrum."

V.—Page 213.—"It is interesting to observe how this plain statement of Dr. Draper demolishes Dr. Piffard's theory, 'that no lines in red, orange, yellow, or green can be photographed, for reasons known to every photographer and physicist.'"

VI.—Jan. 30, 1875.—"I am further reminded 'that the vibrations of heat and light take place in the luminiferous ether, and that the light waves travel at right angles.'"

VII.—Page 213.—"Dr. Piffard states that I misquote him in paragraph nine of my reply. As I have not numbered my paragraphs, I presume he has reference to his luminiferous ether light and heat theory. I most positively deny the charge. I have quoted him verbatim, with the exception of his uncalled for remarks."

VIII.—Page 531, Vol. IX., Oct. 15.—"We will find that these qualities of hamato-crystalline are of the greatest importance in medico-legal cases. When the outer form and integrity of the blood-corpuscles have been destroyed by the various means which the criminal may find within his reach, and when the microscope sends our questions back unanswered, it is yet perfectly practicable to produce the crystals."

IX.—Page 35, Vol. X.—"So also must I maintain what I said in my lecture, 'that when the outer form of the blood-corpuscle is destroyed by chemical or mechanical means, we may demonstrate blood by producing the crystals!'"

X.—Page 85, Vol. X.—"Preyer, the best authority on this subject, says in his work, 'Die Blutkrystalle,' p. 5: 'Blood crystals are not only hamato-cryst.' but Teichmann's Hæmin, Hæmatin, Hæmatoidin, and Hæmatoin.' When and where did I say that from chemically altered blood we may obtain hamato-crystalline? No where."

XI.—"But when Dr. P. says I made an incorrect quotation from Mr. Preyer, I must deny the charge."

XII.—Oct. 15, 1874.—"Kirchof left us a map of these lines, a masterpiece of correctness and skill, containing many hundreds of sun-lines, and our distinguished Rutherford has photographed them right from the sun himself. The exactness of these two mappings is truly wonderful."

quotation marks with extracts I. and II. of Dr. Waterman will show that a mistake has been made in quotation and in meaning.]

V.—[Comparison with Extract No. I. (Dr. Piffard) will show it to be a misquotation. Dr. P. merely denied that the red lines appeared in Draper's map.]

VI.—Nov. 16, '74.—"While the vibrations of heat and light take place in the luminiferous ether, and that the particles of this ether move in a direction at right angles to that in which the waves are progressing."

VII.—Feb. 20, 1875.—"In paragraph ninth of his reply, Dr. W. misquotes me, as reference to THE RECORD of Nov. 16th will show." (See Ext. VI.)

VIII.—Nov. 16, 1874.—"The fact is, that crystals of hamato-crystalline can only be obtained from fresh, and not from dried or chemically altered blood."

IX.—[By reference to Extract VIII. (Waterman) Dr. W. claims in his lecture that hamato-crystalline can be obtained from dried blood; but in Ext. IX. (Waterman) Dr. W. claims that he can demonstrate the blood by producing the crystals, and names several kinds of blood-crystals which can be produced, which Piffard had not disputed.]

X.—Page 134.—"An incorrect quotation from Preyer, in the next paragraph of Dr W's reply, would convey the idea that Preyer places the substance commonly called hamatin among the blood-crystals, which is not a fact, Preyer stating, at page 116 of the same book, that it is an amorphous substance."

XI.—[The original passage in Preyer reads as follows: "Blutkrystalle hingegen heissen auch das Teichmannsche Hæmin, das damit identische Lehmannsche Hæmatin in krystallisirten zustande, und das Virchow'sche Hæmatoidin, wenn es sich krystallinisch in alten Blut extravasaten findet. Auch meine Hæmatoinkrystalle können Blutkrystalle genannt werden," u. s. w.]

In this passage we find that Preyer mentions three kinds of crystals besides hamato-crystalline, as Lehman's hamatin and Teichmann's hamin he expressly states to be identical substances. Waterman in Ext. X. makes Preyer say that there are four kinds besides hamato-crystalline.

XII.—Nov. 16, 1874.—"The facts are, that only a comparatively small number of lines in Kirchof's maps are coincident with those in Rutherford's photograph, due to the fact that the whole mass of lines from A to about F, on Kirchof's map, could not be obtained photographically by Rutherford's processes, and the additional fact that the immense number of lines, more refrangible than the line H, which are found in Rutherford's belong to the ordinarily non-visible portions of the spectrum."

XIII.—Jan. 30, 1875.—"I am not aware that I have anywhere stated that Rutherford photographed ALL sun-lines from the sun itself. I desired to convey the idea that sun-lines were thus photographed, nothing further. The two sections of mappings to which I had reference were those published by Professor Roscoe, in his work, 'Spectrum Analysis,' page 266, second edition; they contain each about 130 sun-lines, lying between E and G, extending from the 194th to the 230th degree of Kirchof's scale."

XIV.—March 20, 1875.—"He says hæmatin has never been crystallized."

XIII.—Feb. 20, 1875.—"Dr. W., in reply to my criticism concerning spectrum photography, states that he referred to the portion of Kirchof's map reproduced in Roscoe, and which contains 'about 130 sun-lines.' Now, in his first paper he refers to Kirchof's map in this connection as containing 'many hundreds of sun-lines.'"

XIV.—[Reference to Ext. 10 will not support this assertion. Dr. P. simply said that Preyer stated that it was not a crystallizable substance.]

G. F. S.

HOSPITAL APPOINTMENTS AND DISAPPOINTMENTS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—One would suppose from reading the letters that have appeared in the columns of *The Tribune* and *MEDICAL RECORD* that the managers of the Presbyterian Hospital had treated their medical staff in a manner almost unprecedented, and the warmth with which the professional friends of the four gentlemen who are aggrieved have publicly and privately espoused their cause would make it appear that the highest rules of honor are observed among members of the profession in their hospital relationships. Early in this controversy—if it can be so called when the talking is all on one side—it was said that only once before had a physician lost his position in a New York hospital in so summary a manner; and even that was justified by the ill-health of the person deposed. But we do not need to go so many years back to find two instances which created so much comment at the time that we might be surprised that no reference had been made to them. did we not know that some of the very gentlemen who signed the "Protest" were the instigators or abettors—so it is generally considered—of the removals.

With your permission I will refresh the memories of some of those letter writers. In 1870 one of the best known physicians in this city and country wrote and published a scientific paper which contained demonstrable facts regarding the mortality of founding children when cared for in public institutions. These statements incurred for him the displeasure of the *First Directress* of one of the hospitals of this city with which this physician was connected, and through the instrumentality of his fellow-members of the medical board he was crowded out of his position with the threat that he must resign or be "dropped." Not the slightest intimation was then made, so far as I am aware, by any of the gentlemen who signed the protest, that the physicians who remained on the medical board had in any way acted in an "unprofessional" manner towards their comrade, nor were there any published sneers at the character or standing of the physician who accepted the position left vacant, and whose name, together with most of those who were members of the board, appears among the signers of the protest.

Less than a year ago the Commissioners of Public Charities and Correction made, without explanation, such a change in the organization of the Medical Board of Bellevue Hospital that several physicians who had served for years in such a manner that they had won credit for themselves and honor for the hospital, were dropped without a word of explanation, or acknowledgment of the services they had rendered.

It has been generally believed (and I have yet to hear it contradicted) that the change was made at the solicitation of other members of the board, for the purpose of advancing the interests of themselves and their friends. Yet these gentlemen have no scruples about signing a protest against the late action of the Board of Managers of the Presbyterian Hospital. Since it has pleased some of the writers in this controversy to speak in an uncomplimentary way of the four physicians who have accepted positions in the Presbyterian Hospital, it may be *apropos* to remark that one of them was appointed on the reorganized Bellevue staff, and nobody took any exception to him in that connection.

The fact of the matter is, that one clique of physicians and surgeons has attempted for years past to manage the appointment of members of the medical boards of several of our important hospitals, and have thus far succeeded so well that some of them hold, individually, appointments in several institutions. Whatever furthers their interests is declared by their friends to be for the interest of the profession, the institution, the cause of medical education, etc., as the case may be, but any action on the part of managers, rival schools or cliques, which attempts to take this control out of their hands is followed by a hue and cry; and one of the striking features of the case is that this is generally done through the secular press. Contrasting the Presbyterian Hospital affair with the others I have mentioned, one is strongly reminded of the fable in the old Webster's spelling-book of the farmer who went to the Justice to settle for the damages done by the farmer's bull, which had gored the Justice's steer. The Justice, it will be remembered, was profuse in his compliments upon the farmer's honesty, until it appeared that it was the farmer's steer that had been gored by the Justice's bull, when, in a remarkable way, the case assumed an entirely different aspect.

VERITAS.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from June 6th to June 12th, 1875.

BACIE DALLAS, Surgeon.—Granted leave of absence for two months. S. O. 114, Mil. Division of the Atlantic, June 7, 1875.

KNICKERBOCKER, B., Assistant Surgeon.—Assigned to temporary duty at Fort Canby, W. T., relieving Assistant Surgeon Brooke, and, upon assignment of another medical officer to duty there, to rejoin his proper station, Fort Vancouver, W. T. S. O. 69, Department of the Columbia, May 27, 1875.

DELANY, ALFRED, Assistant Surgeon.—Granted leave of absence for three months on Surgeon's certificate of disability. S. O. 116, A. G. O., June 11, 1875.

MUNN, C. E., Assistant Surgeon.—Assigned to duty at Camp Robinson, Nebraska. S. O. 67, Department of the Platte, June 4, 1875.

ADAIR, G. W., Assistant Surgeon.—Relieved from duty at Ringgold Barracks, and to proceed to Fort Duncan, Texas, reporting, upon arrival, to Lieut. Colonel Shafter for duty in the field. S. O. 106, Department of Texas, May 31, 1875.

GREEN.—Died, on Saturday, June 5, at the residence of his son-in-law, Dr. Charles Y. Swan, Morristown, Joshua Green, M.D., of Grafton, Mass., aged 77 years.

Medical Items and News.

MORACE WELLS is to have a bronze statue erected in Hartford to his memory, as the discoverer of anesthesia. The Legislature of Connecticut appropriated, some years ago, \$5,000 to be devoted to this purpose, and the city of Hartford gave a like sum. A colossal statue in bronze has been erected by Truman H. Bartlett, and it is proposed that the profession of the country be asked to contribute the amount necessary for defraying the cost of the bronze pedestal. Letters of inquiry may be addressed to Dr. E. K. Hunt, Chairman of the Committee of the Hartford Medical Society. Subscriptions may be forwarded to Dr. G. W. Russel, Treasurer, Hartford, Conn.

DR. B. W. RICHARDSON has been elected President of the Health Department of the Social Science Congress, which is to meet in October next, in Brighton, England.

MEETINGS OF DENTAL ASSOCIATIONS.—The Pennsylvania State Dental Association meets in July, at Cusson Springs, Pa. The American Dental Association meets at Long Branch in August, and the American Dental Society of Europe is to meet during the same month at Hamburg, Germany.

THE FUND FOR THE FLOATING HOSPITAL OF ST. JOHN'S GUILD has been raised to \$9,728.50. The Treasurer is Mr. William H. Guyon.

THE COLLEGE OF PHARMACY, at a recent meeting, elected, as the new Board of Pharmacy for the succeeding three years, Dr. Walter de F. Day, Dr. B. E. Hays, Dr. William Balser, T. Frohwein, and Gustavus Ramsperger. The whole number of registered pharmacists in the city was stated to be 1,178, and the names of five pharmacists who were practising illegally were reported. An explanation was given of the mode of conducting the pharmaceutical examination, and an estimate was made that twenty-five per cent. of the candidates examined by the Board during the three years past had failed to come up to the requirements.

DR. BULLARD, of New Haven, Connecticut, has been in practice for about half a century, during which time he has been present at the births of about one thousand children. Such of these children as survive propose to hold a grand picnic at the doctor's residence, and the whole affair is to be under a committee of arrangements from the adjoining towns.

RESIDENT STAFF, MOUNT SINAI HOSPITAL.—The positions of House Physician (with a salary), Senior and Junior-Assistant Physicians are vacant. Candidates should apply to Dr. Ernst Krackowizer, 16 W. 12th Street.

WEEKLY BULLETIN OF THE MEETINGS OF MEDICAL SOCIETIES.

Monday, June 21.—Medical Society of the County of New York, "On the Genesis of an Epidemic of Puerperal Fever," by William T. Lusk.

Tuesday, June 22.—American Microscopical Society; Yorkville Medical Association.

Wednesday, June 23.—N. Y. Pathological Society.

Thursday, June 24.—N. Y. Medico-Legal Society; Brooklyn Pathological Section; Jersey City Pathological Society.

Friday, June 25.—Medical Library and Journal Assoc'n; Dr. Paul F. Munné, Report on Gynecology.

Original Communications.

TWO CASES OF INTRA-LARYNGEAL GROWTH—TREATMENT BY EXCISION—CURE.

By GEORGE M. LEFFERTS, M.D.,

INSTRUCTOR IN LARYNGOSCOPY, COLLEGE OF PHYSICIANS AND SURGEONS, N. Y., SURGEON TO THE N. Y. EYE AND EAR INFIRMARY (THROAT DEPARTMENT.)

CASE I.—*Fibro-cellular polypus in the anterior commissure of the larynx—Excision with the wire-loop—Ecraseur—Cure.*

Mrs. W., æt. 26. The patient stated that she was unable to fix upon any definite period as the commencement of her throat trouble, but that for years she had suffered more or less from the ordinary symptoms of a chronic catarrhal affection of the larynx—notably, cough varying much in character and frequency, expectoration of thick viscid mucus, especially in the morning, and a constant feeling of dryness and irritation, requiring repeated efforts to clear the throat. She had had attacks of partial aphonia, occurring especially after any exposure, and during the continuance of which the above-mentioned symptoms would increase in severity, and had as a rule experienced but little trouble with her throat during the summers, the difficulty recurring regularly, however, with each succeeding winter. Two years ago she contracted a severe cold, and to this, and to the coincident exposure, she attributes all her subsequent trouble. The symptoms described above became much aggravated; she was for the first time completely aphonic, and slight difficulty in the respiration manifested itself. The latter symptoms, she stated, she had never before noticed, and that they were not sudden in their onset, but gradual and continuous in their character, and that since this period they have progressed with increasing severity up to the present time. The voice is now completely lost, and the patient speaks in a rough whisper, vocalization being attended by considerable muscular and peculiar expiratory efforts, and the use of only a few words at a time. She is completely unable to raise the voice, and states that at times it is unrecognizable. The dyspnoea from which she suffers is very marked, the breathing, both in inspiration and expiration, is noisy and stridulous, and can be heard at some distance from the patient; any exertion increases its amount, and for the last year she has had to carefully avoid any cause for accelerating the frequency of the respirations. She further states that she has had occasional attacks of laryngeal spasm, they being, however, comparatively unimportant, occurring generally during the night, and being of short duration. The cough and expectoration still persist, and in addition she experiences a constant sense of obstruction and fulness in the larynx, with occasional pain on pressure. With the exception of this local trouble she has always enjoyed good health. She has an incomplete syphilitic history, dating back several years, but no evidences of the disease can be seen upon careful examination. Auscultation proves the lungs to be perfectly healthy.

The laryngoscopic examination shows the larynx generally to have been the seat of a chronic catarrhal process of long duration. Hypertrophy of the mucous and sub-mucous tissues is general and very marked, especially in the posterior commissure, where

the thickened membrane lies in folds and irregular projections, and in the region of the false cords, which latter are so much enlarged that they project beyond and over the vocal cords, so as to nearly conceal them.

In the anterior commissure of the larynx is located a large pedunculated fibro-cellular growth, a form of neoplasm comparatively rare in the larynx, occurring in only about five per cent. of the cases of growths reported. It has a pyriform contour, is smooth, and of a pale pink color, and about the size of an almond. Its short, thick pedicle is inserted, as near as can be determined, upon, or just above, the anterior commissure of the vocal cords, and it lies partly upon and partly between the latter, reaching backwards until its apex approaches very nearly the posterior wall of the larynx. The large size of the neoplasm, associated with the hypertrophy of the false cords, causes a considerable diminution in the calibre of the larynx, there being a very marked degree, and consequently dangerous state of *laryngeal stenosis*. An observation with the laryngeal mirror, while attempts at phonation are being made, demonstrates that the vocal cords cannot approach one another during the act on account of the mechanical obstruction presented by the interlying portions of the growth, and that they assume a curved form, approximating posteriorly only. The direct causes, therefore, of the rational symptoms are fully explained by the physical conditions revealed to us by the laryngoscope.

Operative procedures were at once undertaken for the relief of the patient, and the pharyngo-laryngeal parts proving unusually tolerant to the use of instruments, no time was lost in their preliminary training, but the instrument intended to be used for the purpose of extirpating the mass at once brought into requisition, and the operation itself completed at the first sitting.

The instrument alluded to, the wire écraseur, being at the present time much less used than in the early days of laryngoscopic surgery, except for galvanocautic purposes, and the conditions of its successful employment being much modified by certain circumstances in connection with the irritability of the patient's pharynx and larynx, the size of the parts, and the character, situation, and form of the growth, as well as the size and form of the instrument itself, a few words regarding the latest modifications in its mechanism, designed to overcome some of the above conditions, may not be without interest in this connection.

The early instruments consisted either of a single tube, as used by Gibb, or the double canula, on the principle of Gooch's, employed by Walker, curved to a proper angle for entering the larynx, and through which the double wire passed, to terminate at one ex-

tremity in a loop and at the other in a handle, varying in construction, pressure upon which latter drew up the wire-loop and excised the growth. The difficulty with these instruments was in introducing such a loop into the larynx and successfully encircling a growth, unless the case was one which presented unusual facilities for the accomplishment of the act, among these, tolerance of the parts, and a favorable location of the growth either posteriorly or upon the superior parts of the larynx, standing pre-eminent. The exertion of a very small degree of force, either by impingement against the pharyngeal or laryngeal walls during introduction, or caused by contraction of the latter about the loop after entrance into the larynx, were amply sufficient to alter the form which had been given to it before introduction, so much and so materially, that it was no longer adapted to encircle or pass over the given growth, and the operator was compelled again and again, in many cases, to withdraw the instrument and reshape the loop, persevering until at last success crowned his laborious efforts.

The instrument which was devised some time ago by Prof. Stoerk will fulfil many of the indications desired and in a very simple manner—the principle involved being that the wire should be protected from contact and disarrangement, and this is accomplished by covering it with a double oval, rigid, metallic guard, through which the loop, fully protected, runs; and finally, traction being made upon it by means of the handle to which the extremities of the wire are fastened, compresses the growth between itself and the upper edge of the guard. These metal guards are provided of different sizes, so that one principal objection to the instrument, viz., that the loop cannot be made to assume the diverse forms suited to the shape of the variously formed neoplasms to be extirpated, is partly overcome. A second objection which has been urged against érasieurs in general, that the use of the fine wire causes the instrument to act practically as a *guillotine*, and to rather cut than crush off the growth, can hardly be urged against this instrument, which, carrying as it does, a large wire, can hardly cut, but must crush its way; and, furthermore, the pressure being applied gradually, the growth will be removed in strict accordance with the true principle of the érasieur.

The process, of course, requires time, and on this account this form of instrument can only be used, as above stated, in tolerant cases and on growths of some size, which, on account of their location, are readily seized and comparatively quickly removed. Very large growths, or those of a vascular nature, for the removal of which the érasieur is thought necessary, will probably demand the preliminary performance of tracheotomy, as a necessary precaution against disastrous results.

A still further improvement in the instrument—suggested, I believe, by Gibb, but elaborated by Stoerk—and a very desirable one when operating for the removal of small growths, consists in the substitution of a small metal tip, perforated in four directions, for the oval protecting guard. The apertures in this tip are threaded with the wire, the direction of the loop being either in an antero-posterior or transverse line, according to the location of the neoplasm, and the wire being thus held by the holes, is effectually prevented from turning from the given direction—a very common occurrence with the old tube-form of instrument. The wire used with this form of apparatus also assists in attaining this desirable result; that formerly used, thin iron or silver wire, very easily losing its shape if

pressed upon while entering the larynx, and usually requiring many readaptations to the form of the growth. The steel wire, as used for musical instruments, will be found preferable, having the necessary elasticity and firmness, and therefore fulfilling the indications required.

In the case under consideration, the size of the growth rendered the employment of a large guard necessary in order to pass successfully over it, and the difficulty of easy introduction into the larynx was thereby increased, the size of the guard rendering contact with the laryngeal walls almost impossible of avoidance, and the immediate contraction of the parts which followed obstructed somewhat a view of the entire process of extirpation. By introducing the instrument carefully, however, guided by the reflection in the laryngeal mirror, and causing it to enter the larynx far posteriorly between the arytenoid cartilages, where the greatest amount of free space presented itself, it was possible to then pass forwards and see the apex and part of the neoplasm within the loop, before firm pressure forwards and subsequent constriction of the growth were performed. The first attempt failed, owing to the barrier which the hypertrophied false cords presented anteriorly, and the requisite force necessary to press between them and over the growth being under-estimated, and resulted in carrying the whole larynx more or less forwards before the instrument, and consequently altered so materially the relative positions of the growth and the wire-loop, that complete extirpation failed, and only the apex of the neoplasm was removed. On a second attempt, a few moments later, external manipulation of the larynx was called into requisition, and it was found not only practicable, but also easy, while an assistant first elevated the organ and then pressed it slightly backwards and held it steadily, to carry the oval guard, with its contained wire-loop, directly forwards, neatly into the anterior commissure, and upon drawing up the wire to crush through the pedicle of the neoplasm.

Some embarrassment in the respiration attended the procedure, but the amount of dyspnoea was not excessive and caused no anxiety. Immediate improvement followed the extirpation of the growth, the patient drawing deep, full inspirations, unattended by stridor, and expressing herself in marked terms as to the amount of relief that had been afforded, and a subsequent examination with the mirror showed that, the obstruction being removed, the approximation of the vocal cords was nearly perfect. The stump of the pedicle was seen to be located just above their anterior insertion, reaching well down towards their superior surfaces.

The subsequent treatment of the case presenting no unusual or interesting points, may be summed up in a few words. The patient remained under observation and treatment for several weeks, during which time applications directed against the catarrhal condition of the parts were regularly made to the larynx. The progress towards complete cure, though slow, was sure, being delayed only by the chronic form of the disease and the general hypertrophy of the tissues, and resulting finally in the patient's discharge, the voice being clear and forcible, the respiration unembarrassed and easy.

CASE II.—*Papillomatous growths upon both vocal cords—Excision by means of Stoerk's guillotine—Cure.*

The patient, a stout, healthy man, æt. 36, stated that in January, 1872, he suddenly became partially aphonic, and that any prolonged efforts at phonation made at the time were attended with great difficulty and sub-

sequent exhaustion. He knew of no cause for this attack, unless it was due to a prolonged use of the voice in a high and loud key, while under considerable excitement, some few days previously. His business was one that required constant and laborious use of the voice—but he himself had never had his attention called to any change in it, previous to this time—although his friends say that for some months an alteration in it had been apparent to them. He had suffered from time to time from the ordinary symptoms of a catarrhal laryngitis, all of which he considered as being due to exposure. Following this primary attack of aphonia others occurred with more or less frequency, recurring especially after any exertion in speaking, and being progressively more severe and prolonged in their character, until finally, some four months later, he became completely and permanently aphonic, and could make himself intelligible only with difficulty. The respiration was somewhat labored and stridulous in its character, expiration being especially affected, and a curious sensation as of loose bodies flying up in the throat and provoking cough was complained of as occurring with the latter act.

Deglutition had not been interfered with, and he had not as a rule suffered from excessive cough nor expectoration. His general health, as has been stated, was good, and he is free from all syphilitic taint, and has a clear hereditary history. At this time, some four months after the inception of his throat affection, his condition induced him to seek the aid of a colleague, at whose hands he underwent an operation for the removal of the laryngeal growths, which had been diagnosed by means of the mirror. This operation, according to the patient's account, consisted in the extirpation of several small growths from the larynx by means of a tube forceps, and in subsequent cauterizations, and the result gave him considerable relief, although the voice was but slightly improved.

Some weeks later, the intervening time having been spent by the patient at his home in the country, complete aphonia, after a prolonged use of the voice associated with severe exposure, again manifested itself, and the patient lost even the hoarse whisper which had been the result of the former operation, but without impairment of the respiration as formerly. The condition here described grew progressively worse, according to the patient's statement, although it is difficult to see how it could have done so, and he was finally again obliged to seek surgical aid. My examination of the throat in the summer of 1872 gave the following results: The overhanging and curved epiglottis prevented a full and satisfactory view of the interior of the larynx, only the posterior thirds of the vocal cords being visible,—if, however, phonation be forcibly conducted—it was well elevated and a complete view of the laryngeal cavity thereby obtained, showing that a general catarrhal condition of the mucous membrane existed, it being congested, relaxed, and flecked with a profuse, thick mucous secretion. The true vocal cords were in a highly disorganized state, being of a dirty yellowish gray color, relaxed and dotted with small hemorrhagic spots. They were lined on their free edges and throughout their extent with papillomatous outgrowths varying in size and form. These growths were for the most part on the inner and lower edges of the cords, the largest springing from the superior surface of the right cord, in its anterior third, and having the true polypoid form. Anterior to it and lying beneath the cord, growing from the right wing of the thyroid cartilage, was another smaller growth, which projected out into the lumen of the larynx, and which was hidden when the

ords were approximated. The remaining growths were situated along the free edges of the cords, forming a fringe which projected inwards from their in-

ferior boundaries, and were of irregular forms. The superior free edges of the cords were sharply marked.

During phonation the action of the cords was feeble and irregular; when forcible, the cords were adducted anteriorly, the rough tooth-like processes on one vocal cord fitting into corresponding depressions on the edge of its fellow. Posteriorly a wide three-cornered opening remained unenclosed, the arytenoid muscle not having sufficient power to compress the intervening obstructions, and approximate the arytenoid cartilages.

Attempts were at once made to remove the various growths by means of the laryngeal tube-forceps, but owing to their soft and friable nature, the instrument was found to be unsuited for the purposes of complete extirpation, and the guillotine of Prof. Stoerk (a description of which has been given by me in a former article *) was substituted. With this latter instrument it was designed to cut the growths cleanly away from the cords at their bases, or even a line below that point, and to remove them entire, leaving no scattered portions behind to serve as a nucleus for the development of new outgrowths, and the result proved its applicability and thoroughness for all the growths, with the exception of those at the anterior commissure. Three sittings were necessary to effect complete clearance of the vocal cords, followed by one during which the "ball-shaped" cutting forceps of Winter nich were used to remove the small growths at the anterior commissure of the cords.

No untoward incident occurred during these steps of the operation, the patient, being well trained to bear the introduction of instruments into his larynx, bore the various stages of the procedure well; the latter being of short duration and conducted at frequent intervals.

The hemorrhage following the excision of the masses was but slight, and readily checked by cold and astringent gargles, and the application of ice externally over the larynx.

The growths having been removed, approximation of the cords was rendered possible, and the good result of the operation was demonstrated a few days later to the eye, in the nearly perfect closure of the glottis, and to the ear by the full, almost clear, voice with which the patient phonated, especially the higher notes.

This clearness of voice was subject to partial relapses, due either to an accidental access of the catarrhal inflammation of the cords, or to an overuse of the voice, exhausting the impaired nerve-force of the larynx; both of these conditions improved, however, as time elapsed, and some few weeks later the verdict of cure could be pronounced, with a guarded prognosis regarding recurrence of the growths.

* N. Y. MEDICAL RECORD, Vol. 2, 1874.

The treatment pursued during this time is, for the sake of brevity, not given in detail, but consisted in the ordinary applications, stimulant and astringent, recommended for catarrhal conditions of these parts. One point worthy of note, however, is that no application of caustics was, with one exception, made after the operation, although their use for the purpose of destroying the base of growths is generally recommended, as I believe that in the soft form of the laryngeal papilloma, described above, their use is not only inadvisable, but absolutely pernicious, promoting hyperemia, increased cell-proliferation, and rapid recurrence of the neoplasm. This view of a clinical distinction between a soft and hard or nodulated form of papilloma is shared by several writers. The former variety occurring on those parts covered by flat epithelium, and showing the greatest tendency to recurrence, while the latter, termed the *pseudo-papilloma* by Lewin, develops at points in the larynx where a papillary structure does not pre-exist; and that interference with caustics in the first form of neoplasm, after as thorough an extirpation as possible by means of suitable instruments, has been demonstrated by experience to be inadvisable, especially as the low vitality of the small portions remaining after an operation has usually been effectually extinguished by the crushing, and in cases where further treatment has been abstained from, rapid atrophy and entire disappearance, as a rule, occurs.

15 WEST 26TH STREET.

SUICIDE—EXTERNAL APPEARANCES AFTER DEATH BY HANGING.

By M. A. McCLELLAND, M.D.,

KNOXVILLE, ILL.

WM. ARMSTRONG, age 44, plough-maker, weight 200 pounds, was found in an out-house upon his knees, body leaning forward, and suspended by a half-inch rope attached to a beam above. The body was prevented from falling much to either side by the wall of the house on his right and by a seat on the left. The noose around the neck was prepared from a piece of packing, such as machinists use about engines. It was just sufficiently long to tie to the end of the rope and to form a noose with a loose knot. When twisted it would make a cord about half an inch in diameter. When I saw it, two hours after it was removed from the neck, it did not seem to have been twisted.

He was found about 9 o'clock A.M., May 30th, 1875. Probable time of death from two to four hours before. I saw him at 10.30 A.M.

No *rigor mortis*. Face and eyelids livid, but not swollen. Eyes slightly injected, but not projecting. Pupils moderately dilated. Tongue livid and the tip between the teeth. Lower jaw not retracted. No bloody froth about nose or mouth. Mark of the noose around the neck. Greatest width a little to the right of *Ponum Adami*, being about half an inch. Depth at same point one-fourth of an inch, shading off both in width and depth to a mere impression just beneath the occipital protuberance. In front the depression was immediately over os hyoides and superior border of thyroid. Hyoid appeared to be fractured. The man was quite fleshy about the neck, and no incision was made to determine this point. The skin in the depression was horny and parchment-like, yellowish-brown in color at its deepest part, gradually becoming livid as it passed backward. The border of the depression, both above and below, was sharply defined

by a deep purple line one-sixteenth of an inch wide; beyond this the lividity was much less marked upward to the face, and downward to the chest, the greater portion of which from clavicles to fourth intercostal spaces was only mottled. The hands, fingers, and nails were quite blue. The ears were purple-blue.

Six hours later *rigor mortis* complete. The posterior part of body from neck to popliteal spaces strongly marked with *post-mortem* stains, hypostatic congestion.

An abrasion was found upon the front of right thigh, just above the knee. No wounds elsewhere upon the body or scalp. No hemorrhage. No escape of feces or urine, both of which had probably been passed immediately before the hanging. The scrotum was very blue, except a line including the raphe, three-eighths of an inch wide, which was of a natural color. This was so marked as to immediately attract attention on uncovering the parts.

Other circumstances pointed so plainly to the case being one of suicide, no internal examination was required by the coroner.

I testified that the external appearances found were those that usually followed death by hanging, but that the mark of the cord upon the neck was not incompatible with hanging after death.

ERGOT IN THE TREATMENT OF INSANITY.

By EDWARD C. MANN, M.D.,

MEDICAL SUPERINTENDENT STATE EMIGRANT INSANE ASYLUM, WARD'S ISLAND, N. Y.

SOME years have elapsed since Dr. J. Crichton Browne, the Medical Superintendent of the West Riding Asylum for the Insane, wrote an article advocating the use of ergot in the treatment of mental diseases; and since that time a few members of the profession have availed themselves of its use. The majority of the profession in this country are, however, to day ignorant of the great therapeutic value which this medicine possesses when used with discrimination in the treatment of mental diseases.

It was proved years ago by the researches of Brown-Séquard and others that ergot possessed the power of producing contraction in the vessels of the spinal cord, and accordingly it occurred to Dr. Browne that it might possess a similar control over the vessels of the brain, and might thus be made to modify or remove the active cerebral congestion which is an attendant upon so many phases of insanity. Upon thorough investigation he found that there were three varieties of insanity in which it was eminently useful, namely, recurrent mania, chronic mania with lucid intervals, and lastly, epileptic mania. Dr. Browne and other observers who have adopted the use of ergot in the treatment of insanity, have found that in the varieties above mentioned it was almost uniformly successful in reducing excitement, in shortening the attacks, in widening the intervals between them, sometimes in preventing their recurrence entirely, and in warding off the dangerous stage of exhaustion by which maniacal excitement is so often succeeded. The way in which ergot operates upon the contractile coats of the vessels has been proved to be by its influence upon the non-striated muscular fibres and cells contained in their coats, thereby exercising a controlling power over the calibre of the intracranial vessels. In the three varieties of insanity before referred to,—in recurrent mania, in chronic mania with lucid intervals, and in epileptic mania,—we find that the lesion consists essentially in cerebral hyperemia. We find, although the

symptoms differ in these three forms of mental disease in which ergot is useful, that there is present in each form increased arterial pulsation, flushing of the face, suffusion of the eyes, dryness of the mouth, and cephalalgia. The disappearance of these phenomena in the intervals of the paroxysms, proves that they are dependent upon functional and not organic changes in the brain, in which latter case we should not expect to find any marked efficacy from the use of ergot, and indeed we often meet with instances in which the controlling power of ergot is after a time lost, as organic degeneration gradually follows as a sequence upon repeated attacks of mania. In epileptic mania it will be found that a combination of bromide of sodium with ergot will materially aid the action of the latter in widening the intervals between the fits, and in modifying the attacks when they occur. This combination will also often arrest paroxysms in the incipient stage. The stage of excitement which often precedes and ushers in the attack, and which sometimes succeeds it, is markedly diminished by the combination of the bromide of sodium and ergot. The bromide of sodium will be found to be preferable to the bromide of potassium, as it is pleasanter to the taste and causes less constitutional disturbance than the latter when given in large doses. Dr. Browne remarks that "it is in epileptic mania that ergot has been found pre-eminently valuable in allaying and abolishing excitement, and in conducing to a healthier tone of mental action. In the outbursts of violent agitation, which precede or follow a fit or group of fits, which occasionally take their place, and which have been pronounced by all authorities to be of so dangerous a character, it exerts a prompt and energetic effect. We may presume that these outbursts are dependent upon a want of equilibrium in the intracranial circulation, primarily disturbed by the epileptic seizure or condition. The distension of the vessels, which succeeds their spasmodic contraction and produces coma, subsides so far as to allow the resumption of activity by the higher centres, but only in an irregular and distorted way. And we may presume, further, that the soothing and rectifying effects of ergot are due to its power of re-establishing that disturbed equilibrium."

A thorough trial of the ergot treatment has satisfied the writer of its efficacy in asylum practice, and the following clinical cases will serve to illustrate its beneficial action. The doses of ergot used in the following cases have been from $\frac{1}{2}$ ss. to $\frac{1}{2}$ i. of Squibbs' fluid extract, three times a day, and in cases in which ergotine has been employed, from 5 to 10 gr. have been given. No unpleasant effects have ever followed even prolonged administration of the ergot, and from our experience with it, it would seem that the danger of injurious effects from the continued use of ergot has been greatly overrated by the majority of the profession. Dr. Browne, who has used the ergot treatment for many years in many hundreds of cases, says: "Indeed, so little have injurious effects of any kind followed even the prolonged exhibition of what might be termed enormous doses of ergot, that doubts might have arisen as to whether it were possible to produce that train of symptoms described as ergotism, by means of the medicinal preparations of *secale cornutum*."

CASE I.—Miss E. K.—, with recurrent mania, admitted to the asylum Jan. 11th, 1873, aged 22 years; occupation servant, native of Ireland. Was very noisy and maniacal when admitted. Was very incoherent in speech and boisterous; had no realization of her condition or surroundings. She entertained the idea that people were trying to kill her and get her

property. She destroyed her clothing, broke the windows, did much damage to the furniture, and imagined that she saw snakes and devils in her room at night. She required restraint very often, and continued in this excited state for over a year with no mental improvement. She commenced to take the fluid extract of ergot in $\frac{1}{2}$ i. doses three times a day, on the 15th of June, 1874, and had only taken a few doses before beneficial results were very apparent. The excitement subsided, and she became quiet and peaceable. The congestion of the head and face which was very marked, has nearly entirely disappeared. Her pulse was reduced from 145 to 90. The temperature in the axilla from $99\frac{1}{10}^{\circ}$ to 98° , and her tongue, which was thickly furred, presents a normal appearance. At the present time she assists in the washing, and is very polite and quite cheerful.

Miss M. K.—, a native of Ireland, aged 28 years, was admitted to the asylum June 11th, 1874. Form of mental disease, chronic mania with lucid intervals. On admission was very violent and abusive, requiring restraint; would strike and bite the attendants if not restrained. Her face was deeply congested, eyes injected, tongue coated with a thick white fur, pulse 130, and temperature 99° . Having continued in this excitable state for some days, with no evidence of improvement, was ordered $\frac{1}{2}$ i. of the fluid extract of ergot three times a day. By the 24th of June she began to show decided signs of improvement, and in place of being filthy and abusive in language and conduct, was polite and neat in her habits. She also began to sleep at night, which she had not done before, although medicine had been given for that purpose.

Her pulse was lowered to 85. Her temperature decreased, the suffusion of the eyes disappeared, and at the present time, April 28th, she has had no relapse of maniacal excitement.

E. Z.—, a native of Germany, aged 27, a mechanic, was admitted to the asylum June 12, 1874, suffering from an attack of acute mania, caused by overwork and mental anxiety. Had always been a healthy man, and no trace of insanity in the family history. Upon admission was very noisy and maniacal, and his great strength rendered restraint necessary, as he endeavored to injure every one about him. He was ordered a warm bath, which relieved him for about half an hour, when he again became maniacal and dangerous. Was given chloral and hyoseyanum, and passed a restless night. In the morning he presented very much the same appearance as on the preceding evening. Face and eyes suffused and congested, pulse 100, and temperature heightened; tongue thickly coated and mouth dry; was put on $\frac{1}{2}$ i. of the fluid extract of ergot three times a day, and chloral and hyoseyanum at night. In a few days the excitement began to subside, and, August 1st, was comparatively quiet. August 15th, pulse 80, temperature $97\frac{8}{10}^{\circ}$, appearance of tongue normal. Has remained quiet up to the present time. Appetite good, sleeps well, and is cheerful, although anxious to get back to his family.

Miss S. H.—, native of Ireland, aged 25 years, was admitted to the Asylum Sept. 2d, 1872, with epileptic mania. From the time of admission to June, 1874, had a great many epileptic seizures, which were preceded and followed by attacks of maniacal excitement which rendered her a dangerous patient. Had been under restraint many times. July 24, 1874, became very noisy and excited, as is her habit before her fits, threatening to kill the patients and attendants. The eyes were suffused, mouth dry, pulse 140, and tongue furred. Was put on $\frac{1}{2}$ i. doses of fluid extract of ergot three times a day. After taking the ergot for two days,

she became quiet, and the epileptic seizure which followed was very mild as compared with preceding ones. The ergot was continued, and since that time she has had no return of the maniacal excitement. The fits have decreased in frequency and intensity, and are not followed, as formerly, by any mental excitement. Her physical condition has also been markedly improved since she has taken the ergot. The pulse is now 75 and the temperature in the axilla 98°; eats and sleeps well, and assists in the work.

M. C.—, native of Ireland, aged 30, was admitted to the Asylum about two years ago with epileptic mania. He was a strong, muscular man, and had been subject to epileptic fits for some years. For a period of from a week to two or three days preceding the fits was entirely unmanageable and a very dangerous man to deal with. Required to be restrained. He was also accustomed to have a period of maniacal excitement following the epileptic seizures, which lasted for a variable period, during which time his pulse would range from 100 to 120, and the face would be deeply congested. Was put on \bar{z} i. doses of fluid extract ergot three times a day, and this dose continued for a period of two months, sometimes omitting the medicine for a week and then resuming it. The fits immediately decreased in frequency and intensity, and the maniacal excitement entirely disappeared. Pulse and temperature became normal. He expressed a desire to work, and a short time ago returned in comparatively good health to Ireland.

Several other cases have exhibited as marked improvement under the ergot treatment as the foregoing, but want of space forbids their insertion.

Before closing we would call attention to some investigations assisted by the use of the microscope as to the state of the blood and urine in the insane. A microscopical examination of blood from insane patients, as compared with an examination of blood from the same number of healthy individuals, revealed in the blood of the insane a condition of leucocythæmia, or a marked increase of the number of white corpuscles. This condition has also been remarked by other observers, and Dr. Charlton Bastain and Dr. Blandford have described a plugging or stopping up of the cerebral vessel by small embolic masses composed of collections of white corpuscles, in cases of acute mania and delirium. It has also been found that during the period of maniacal excitement, that there is a marked diminution of fibrine in the blood, and that during convalescence the amount of fibrine is increased to the normal standard. These results have been confirmed by the recent researches of Hittorf, Erlenmayer, Michea, and Dr. Marcet. Examination of the urine of the insane has shown that in acute mania there is an excessive elimination of the phosphates as a rule, while in dementia, general paralysis, and chronic mania, the amount of phosphates eliminated is generally below the average. There has been some difference of opinion in different observers as to the reaction of the urine in insanity, Erlenmayer claiming that it is generally alkaline in recent cases of mania, while Dr. Sutherland, who has paid great attention to the condition of the urine in insanity, found that in 125 cases of recent mania, the urine was acid 101 times and alkaline 13 times, and gave a neutral reaction once. In our investigations we have found the reaction to be acid in the majority of cases of those affected with acute and chronic mania and dementia.

The small amount of time at the disposal of a physician in charge of an Asylum, and the difficulty of making an extended course of investigation in the analysis of blood and urine, which is so desirable in

the study of insanity, and also the difficulty of making microscopical researches, are causes which have combined heretofore to deter the superintendents of Asylums in this country from giving to the profession the results of their valuable experience, and it is therefore to be hoped that the time is not far distant when every Asylum shall possess the services of a skilled pathologist and chemist.

HYPOSPADIAS—TWO CASES RELIEVED BY OPERATIONS.

By E. BRADLEY, M.D.,

NEW YORK.

THE first case was that of a gentleman who came under my care with the following condition of the genitals: The penis was one and one-quarter inches in length, and solid, having no urethra, or any trace of one except at the place where the meatus ought to be, and at that point there was only a slight furrow. The testicles were enclosed in separate sacs, and the division of the sacs was in the median line, and was carried up to the perineum. The testicles were large and unusually well developed. The penis was drawn up between the testicles, and rested on the floor of the perineum, and when patient stood erect only a trace of the rudimentary penis could be seen, it being concealed by the separate sacs closing over it, and the parts had very much the appearance of the female vulva. At the root of the penis was an opening, leading into the bladder, which admitted a No. 12 English sound easily, and through which the patient evacuated the bladder while in a sitting position. The patient was very well developed physically, had frequent erections, seminal emissions, and his sexual desire was strong. I operated, by making three V-shaped incisions, along the under border of penis, cut the contracting bands which held the penis in its curved position, and strapping the organ firmly against the abdomen, allowed it to heal. After a few weeks, the organ was found to measure three inches, a similar operation was again performed, with a further gain of an additional inch. After waiting several months for the cicatrix to become softened and absorbed, I made a straight incision along the centre and under surface of the penis, and dissecting flaps upon either side, from the end of penis to the perineal opening, I introduced a silver tube, flattened on one side, and having that side down; brought the flaps over the tube, and united with very fine sutures. The tube was moved, after forty-eight hours, very gently, and the parts allowed to heal over it. After considerable trouble one and one-half inches of the flaps from the opening into bladder towards the end of penis united, and by a subsequent operation scarifying the edges of the opening into the bladder, and the edges of the adjacent ends of the flaps which had been made, and bringing them together, they were made to heal over a catheter kept in the canal for the passage of the urine. The patient could then pass water in the erect position, and seemed to be very proud of the seeming transformation of his sex. And although he did not pass water out of the end of the organ, yet he was satisfied, as the erectile powers were as good as ever. He soon after married, and at last accounts was living happily with his wife; although he has never had any children, his seminal fluid contains spermatozoids in abundance.

The second case was similar in every respect, as regards the appearance of the genitals. The patient was thirty-three years of age, a large, fine looking, well-developed man, who had dressed and passed as a

female for twenty-five years, having been pronounced one by his family and their attending physician. He worked in a factory among females for ten years, and slept with one as companion most of the time. After arriving at the age of puberty, he had great difficulty in concealing his beard, and eight years ago he came to this city and changed his female apparel for that of a male. And although he has been in male attire ever since, yet there is something about his actions and manners which reminds one of a female.

I performed the same operation on him, and after eighteen months, and three operations, I succeeded in getting four and a half inches of penis for him, and am now waiting to allow the parts to heal thoroughly, when I propose to do the following operation: Pass a straight steel instrument (similar to Dr. Bumstead's smallest size instrument for the division of stricture, but pointed and sharp at the end) down through the penis, starting at the fissure where the meatus ought to be; carrying it down until it meets the opening into bladder, and then, by a judicious use of the knife in the groove on the upper edge of the instrument, enlarge the opening until it will admit a No. 8 catheter or tube. By allowing the tube to remain, and by moving it gradually, I expect to establish a canal, and if this can be done I shall close the opening in the perineum by scarifying its edges and uniting them.

I think this operation bids fair to give me better results than the plastic operation performed on the first patient. I am, however, fully open to suggestions on this point, and would be very thankful to receive them. The operations performed were attended with considerable hemorrhage, especially at night when the erections took place.

Progress of Medical Science.

MALUM PERFORANS PEDIS.—Professor Fischer, of Breslau, has lately given an interesting review of what is known about the disease to which Vesignic gave the name mal perforant du pied, and he also adds seven cases observed by himself. The multiplicity of writings on this subject has not, he thinks, tended to a clearer understanding of it. Leplat is found to have given the clearest characterization of the symptoms, which he groups in three stages.

The *first* begins with a callous thickening of the epidermis of the sole of the foot at a point where the bones are prominent, and the soft parts subjected to considerable pressure in walking and standing. This callosity is either white, or it may be stained by effusions of blood between its layers. The underlying skin, at first unaltered, subsequently becomes thickened and atrophic, with diminished sensibility. In the *second* stage pus develops under the callosity, and a round, funnel-shaped ulcer ultimately forms, which has a great tendency to penetrate deeply into the foot. The *third* stage is marked by an extension of the inflammation, if the foot is used, to the synovial cavities and joints. In the *fourth* stage, phlegmonous inflammations extend over the whole foot; there are acute pains, with caries of the bones and destruction of the joints by suppuration. Fischer adds these further characteristics: The process begins at the surface and makes its way uninterruptedly inward to the bones and joints. Its course is chronic and free from pain, certainly until an advanced stage. It obstinately resists all kinds of local treatment. It exhibits a great tendency to relapses, and to attack the most different

parts of one or both feet successively. It is also noticeable that these relapses occur even if the patient remains in bed and wears nothing on the feet. Another prominent characteristic is found in the lesions of sensibility in the neighborhood of the ulcer, and in the whole limb, consisting of a mixture of anesthesia and analgesia, the latter involving a larger area than the former. Fischer regards this last character as so essential that he would exclude from the category of mal perforant all cases in which the sensibility remained normal. Then there are associated nutritive lesions, involving the various tissues of the foot and limb, and amounting in some cases even to gangrene, and these our author regards as quite constant. The disease is observed most often in men, in persons belonging to the lower classes, and in those over forty years of age. With regard to the pathological anatomy, the blood-vessels and nerves have engaged special attention, but nothing positive seems to have been established as to the real condition of things. With regard to the pathogenesis of the disease, too, there have been various theories differing widely from one another, and none universally accepted as correct. Thus we find it considered as an ordinary ulcer in an extraordinary situation; an inflammation and suppuration of the callosities and bursæ of the foot; a decubital ulcer or form of gangrene from pressure; an ulcer originating in occlusion of the sweat glands; a result of a primary disease of the bones; a canceroid; as due to inveterate syphilis, in connection with the fact that iodide of potassium is often useful in the treatment; it has also been referred to uræmic and glycosæmic sources, and some have regarded it as identical with psoriasis plantaris. A large number of surgeons refer the disease to an affection of the vessels; some to atheroma, in regard to which our author agrees with Duplay, whom he quotes as saying that the lesion of the vessels, far from being a primary disease, is a wholly local secondary change. Fischer also rejects embolism as an explanation. In conclusion, he expresses his own conviction that the mal perforant is the deepest and most malignant form of neuro-paralytic ulceration. It may be regarded as a symptom of leprosy, though not a leprous ulcer. It is accompanied by lesions of the innervation and nutrition of the parts which are allied to those of leprosy, and it occurs quite constantly in connection with injury of the mixed nerves. Such injury, with the diminished sensibility which accompanies it, is doubtless an important factor in the causation of the callosity and subsequent ulceration, by making it possible for the individual to endure a degree of pressure on an unprotected part, which he could not if the nerves were normally sensitive. Still even this will not suffice to explain all cases. The first and severest result of the deficient nervous influence appears to be the diseased condition of the blood-vessels, and to this latter Fischer ascribes the nutritive changes. He protests against classing every obstinate ulcer of the foot as mal perforant, and declares that when thoroughly sifted, those cases which can properly be so called will be found to be neuro-paralytic ulcers. As to treatment, he recommends electricity to restore the function of the nerves, which will be followed by cure of the ulcer. If the nerves cannot be restored to health, amputation is the only resource.—*Archiv für klin. Chirurgie*, xviii., 2, 1875.

THE RELATIVE ANTISEPTIC PROPERTIES OF SALICYLIC AND CARBOLIC ACIDS.—Salicylic acid as now prepared by the method of Kolbe consists of a white powder, slightly soluble in water, but easily in alcohol, the solution giving a characteristic violet reaction with

chloride of iron. With the view of ascertaining the relative antiseptic properties of salicylic and carbolic acids, Julius Müller, an apothecary of Breslau, undertook a series of experiments. Adding solutions of carbolic and salicylic acids to a solution of grape sugar and yeast, in the proportion of 1 to 2,500, the salicylic solution was found to prevent the fermentation for twenty-four hours, while carbolic acid in a similar proportion produced no effect. He found that fresh urine, to which carbolic acid was added in the proportion of 1 to 500 and 1,000, remained entirely unaltered at the end of eight weeks, while urine treated with similar amounts of salicylic acid became turbid after five or six days, and soon developed mould fungi and became alkaline. One per cent. of salicylic acid, however, preserved the urine fresh and clear for eight weeks. Results similar to the last followed when these acids were added to solutions in which finely divided portions of liver were put. Thus it appears that a salicylic acid solution, when added to fresh yeast, retards its action upon grape sugar when much more diluted than carbolic acid, but that it offers much less resistance than the latter to the development of the mould spores contained in the air. The author suggests that this may be explained by the greater volatility of the carbolic acid. Pursuing his experiments with non-organized ferments our author found that salicylic acid, in the proportion of $\frac{1}{10}$ to $\frac{1}{20}$ per cent. of the solution, was efficient in preventing the decomposition of amygdalin by emulsin, in delaying and arresting the action of ptyalin upon starch, and the conversion of glycogen into sugar in a solution containing fresh liver, while it required a 10 per cent. solution of carbolic acid to effect the same results. In experiments upon the digestive action of pepsin the results attained were similar, but the difference between the two acids was not so great. That salicylic acid does not arrest digestion in the same way when taken into the stomach of the living animal, as was proved by trial both on man and rabbits, he attributes to the rapidity with which it is eliminated from the system. The author considers the efficiency of the salicylic acid as an antiseptic and antifermentative as due largely to its acid quality. He believes that it will not supersede carbolic acid, because the latter combines so readily with oil and with glycerine, which is of great practical advantage, and because of its antiseptic advantages due to its volatility. Salicylic acid, however, having no smell and not being irritating, will, he thinks, be largely employed in cases where carbolic acid is indicated, but cannot be used because of these defects. An aqueous solution may be obtained by dissolving one part of salicylic acid in twenty parts of hot glycerine and adding to this eighty parts of water.—*Berl. Klin. Woch.*, May 10, 1875.

SALICYLIC ACID IN THE TREATMENT OF CATARRH OF THE URINARY ORGANS WITH ALKALINE FERMENTATION OF THE URINE.—Taking the hint from Kolbe's statement that a small proportion of salicylic acid will arrest the alkaline fermentation of stagnant urine and destroy the bacteria found in its sediment, and remembering that this substance is largely eliminated as such in the urine, Dr. Fürbringer, of Heidelberg, gave it internally in some cases of cystitis, pyelitis, etc., and has made a partial report of the results. The first of the four cases that he reports was one of advanced phthisis and spinal paralysis, in which the urine became fetid and alkaline, and had a deposit consisting of crystalline salts, pus corpuscles, and bacteria. After about 77 grains of salicylic acid had been taken in divided doses the urine became acid and lost its bad smell, and only pus cells with very few bacteria were

found in the sediment. The second was a case of chronic Bright's disease, complicated with catarrh of the urinary tract. The urine was highly alkaline when passed, its sediment essentially the same as in the last case, and it also contained albumen. There were also symptoms referable to an enlarged and sensitive prostate. He was given salicylic acid in the average dose of 15 grains a day, and this was continued for nine days, with gradual improvement in the characters of the urine and finally a disappearance of all bad features except those due to the chronic Bright's disease, viz., casts, albumen, and a few red blood-corpuscles. The third case was one of cystitis of many years' standing, requiring the daily use of a catheter, and in which the characters of the urine and its sediment were similar to the last, the bacteria being very numerous. Salicylic acid was given internally in daily doses of 15 to 30 grains for some twelve days without effecting an important change in the urine. On the supposition that a mass of mucus adhering to the walls of the bladder might be acting as a ferment and keeping up the alkalinity of the urine and the supply of bacteria to an extent which the amount of the acid present in the urine could not overcome, it was determined to wash out the bladder thoroughly with warm water and with a weak solution of salicylic acid. This was done for three days, the medicine being continued internally, and on the fourth day the urine was found to contain no bacteria, but only pus cells and epithelium, and to be acid. The fourth case was one of acute cystitis, in which the alkalinity, the bad smell, and the bacteria developed in the urine were removed by the internal use of the salicylic acid as above, while the pus remained unaffected. From these cases the author feels justified in concluding, 1st, that the internal administration of salicylic acid in quite small doses will do away with the irritation and results of the ammoniacal urine within the organism; but 2d, that it is not capable of checking the formation of pus cells on the mucous membranes of the urinary passages.—*Berl. Klin. Woch.*, May 10, 1875.

A CASE OF MARIOLIN'S ULCER.—A case of the above disease under the care of Mr. Wm. L. Wheeler, of the City of Dublin Hospital, has been reported with the following history: The patient was a man aged 46. When five years of age he was badly burned about the left knee and foot, and left hand. When about 33 years of age he observed a "sort of pimple" break out on the lower end of the ulna, which increased to about the size of a sixpence; for this he was treated for a few days, without any apparent change in the sore. Until three years ago it remained almost quiescent, when it commenced to spread around the wrist, until it entirely encircled the joint. The ulceration also spread so as to open the ulnar artery, causing considerable hemorrhage; this latter accident happening about three months before the patient's admission to hospital. Subsequently the ulnar and median nerves became involved, causing numbness of the entire hand. On admission to hospital he was suffering intense pain, and was in poor condition. Under general treatment he improved so much that in a couple of weeks he was in a fit condition to undergo amputation, which was performed by Mr. Wheeler, close to the shoulder-joint. After the operation, on close examination, two inches of the ulna were found eaten away; the ulna artery destroyed for about three inches, the ulnar nerve eaten across, and the median nerve partially; the scaphoid, semilunar, cuneiform and pisiform bones were all absent.—*The Medical Press and Circular*, May 3, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

MEDICAL ADVERTISING.

The subject of medical advertising still occupies professional attention, and as yet gives no promise of wearing itself threadbare by continued discussion. The remarks which we have made bearing upon it seem to challenge such criticism from certain quarters, that we almost flatter ourselves we have given some new interpretation to the letter and spirit of the Code. We have all along imagined that it was well understood by the profession that there were certain points connected with it concerning which, with fair-minded individuals, there could be no question. But that the case is otherwise is quite evident from the various anonymous communications which have lately appeared in one of the daily papers, criticising the course of *THE RECORD*. Far from regretting the same which we have taken, it is a matter of considerable congratulation to us that we have been chosen as the target for the anathemas of those who desire to find some excuse for wrongdoing. There is, in fact, only one interpretation to be placed upon these letters. There are a few medical men who are striving by underhanded means to create a public sentiment in their own favor, and win for themselves the reputation of martyrs to an opinion. They are not backward in wilfully misrepresenting the sentiments of their brethren, and in charging them with acts which savor of illiberality, injustice, and intolerance. We have the strange anomaly presented of men who appear to take a pride in being considered respectable physicians, and yet are ever ready to revile that respectability. There is a little proverb concerning the bird that fouls its own nest, the application of which some of these gentlemen may have forgotten.

The sympathy of the public can always be gained by showing a disinterested purpose to serve it. This is the aim of these advocates of advertising. They have an intense desire to benefit their race, but the pro-

fession stand in their way. What a pity for the world, and what a shame for the profession! As an instance of the manner in which misrepresentations are made, in order to prejudice the public, we quote from a recent letter in the *Tribune*, evidently written by one who has been advertising himself, and who desires to continue to do so:

"Your correspondent 'Adverto' is not the only physician who has been held up to the gaze of his medical brethren by the high-toned and public-spirited editor of the medical weekly to which he refers. In the eyes of this self-appointed censor any physician who does not hide himself in his closet is guilty of advertising. If he writes a letter to a newspaper on some topic of public interest, he is advertising; if he signs a statement of any kind, and it gets into the public press, he is advertising; if he delivers a lecture before some society and it is published and quoted from by a daily journal, he is advertising; if he (be) so unfortunate as to be alluded to in a complimentary manner for any benefit he may have conferred upon the world by his discoveries or teachings, he is advertising in a most insidious manner. Now, sir, is it not time that all this humbug should be stopped? for I assure you it is the offspring of the most consummate envy, jealousy, and littleness."

On its face, as a statement to the public, this looks rather bad for *THE RECORD*, but more especially for the profession, in behalf of which it presumes to speak. The fact is that we have run the risk of being quite liberal on many points referred to by our anonymous friend. We have always believed in educating the public on medical matters. This is one of the duties which we have urged upon the profession, and which can be performed without violating the Code, or, in other words, advertising the individual. The main difficulty in the way of a consummation of this wish is, that the truly representative men in our profession are afraid to run the risk. Their natural modesty too often gets the better of their judgment. Perhaps, too, they are loth to establish a precedent which might be misinterpreted by their weaker brethren. Such men we could trust to write letters "on topics of public interest," "to sign statements," to deliver lectures, and to confer benefits upon the world by their "discoveries" and "teachings." That they are not yet ready to do it is a matter of regret.

There are plenty of subjects concerning which the public desire information, but this information can be given independent of any desire to bid for practice. In one case the medical man speaks for his profession, but in the other case he speaks for himself; in one case he is a leader of public opinion, but in the other, a pretentious quack. We care not in what guise or form a medical man may appear in the public prints, if his motive is to directly or indirectly gain practice thereby, or to elevate himself at the expense of his brethren, he is an advertiser, and as such we shall always condemn him, and always hold him up to the

"gaze of his medical brethren." We are willing to be liberal on all other points connected with medical writing for the daily papers, but in this, even at the cost of being considered envious, jealous, or bigoted, we confess ourselves somewhat radical.

As an argument in favor of his position, the anonymous correspondent in the *Tribune* quotes a notice made of THE RECORD and of its editor, in the *Evening Post*. For the opinion of the writer of that notice we are in no manner responsible; he spoke of THE RECORD as a journal, and of its editor as a journalist; but how this can be construed into any medical advertising on our part we are at a loss to determine. The low-minded insinuation that we probably dictated the notice ourselves is unworthy of serious consideration.

MEETING OF THE PENNSYLVANIA STATE MEDICAL SOCIETY.

THE recent meeting of this Society at Pottsville was interesting, mainly from the absence of all the distracting elements which have characterized its predecessors. The papers presented were valuable contributions to the literature of modern medicine and surgery, and as such gave intellectual force to the whole proceeding; but the harmony which seemed to prevail in all the business of the meetings was quite as conspicuous a feature, and evinced the existence of a healthy moral tone in the profession of our sister State which is very commendable. We can scarcely recall, at this moment, a meeting of this State Society in which some element of temporary discord has not been thrust into the foreground, and thrown a damper on the unanimity of feeling among the delegates. We remember how, but a few years ago, the woman question was the all-absorbing theme of discussion on which the members flittered away valuable time, year after year, until by a bare majority the earnest efforts of the friends of the sex triumphed, and the target was permanently removed. Petty quarrels of members of local societies were annually disinterred from temporary receiving-vaults, in which they had been laid away, carefully embalmed, in order to have experimental efforts at resuscitation made upon them, previous to their permanent burial. The meeting this year was more like that of a happy family, whose members were capable only of cordial greeting and brotherly love. May this truce to all bickerings and jealousy be enduring! As an evidence of the improved temper of the Society, we may allude to the effect of the address of the President, Dr. Washington L. Atlee, which was markedly a defence of woman in her professional aspirations and endeavors, even while he satirized her external follies of dress and fashion. Had these laudatory remarks been uttered three or four years ago so openly and fearlessly, they would have excited a storm of heated argument, and have seriously disturbed the general harmony. Not a word of opposition was heard, and although the sentiment of the Society must

have been much divided, it was deemed undesirable to rekindle the ashes of the past. The very fact that a President was selected last year who was in former years a most earnest advocate of the practice of medicine by women is an evidence, independent of his brilliant reputation as a surgeon and an ovariologist, that the hatchet had been buried, and that a desire for harmony and peace prevailed.

There seemed to be an earnest effort on the part of this body to encourage all the counties to form medical societies, and send representatives to the parent organization. There are about seventy counties in that State, and yet we find scarcely more than thirty represented at this meeting. We believe there is much fraternity of professional ardor, intelligence, and courtesy now lying dormant in some of the less central counties that might be awakened by judicious efforts, for we believe that local societies produce the friction which will often remove the rust and roughness inseparably associated with isolated labor. Left to himself, the professional man is often prone to forget that he is only a part of the general machinery, which, with the united efforts of others in the same cause, may be moved to useful and practical results. Our Pennsylvania medical brethren seem to have taken high ground also upon the subject of education of children, of hygiene, etc., and we trust that their efforts to procure the establishment of a State Board of Health by the Legislature may prove successful. This is one of the legitimate methods in which medical assistance can be invoked to procure the passage of measures for the improvement of the general health of the community. In other cases such interference is frequently neither desirable nor expedient.

SCHOOL FOR NURSES.—The Commissioners of Public Charities and Correction purpose opening a School for Nurses, at Charity Hospital, on the first day of August next. It is their design to offer to worthy young women, between the ages of twenty and thirty-five, the opportunity to acquire proficiency in a pursuit which is at once honorable, useful, and remunerative, by educating them in the profession of nursing. Every effort will be made to elevate the occupation, by a course of careful instruction from competent teachers, and by considerate and generous treatment of the pupils. The course of training will occupy two years, and will embrace lectures upon nursing, food, ventilation, midwifery, and all subjects connected with nursing.

The lectures will be given by physicians connected with the hospital, and will include a course of twelve lectures upon each subject every six months, and frequent instruction at the bedside.

At the expiration of two years the nurses will be examined by a Committee of Physicians, and those who are competent and qualified will receive a diploma, signed by the Commissioners of Charities and Correction, and the Examining Committee.

Applications, stating name in full, age, and names of clergyman and family physician, should be addressed to

JOSHUA PHILLIPS, *Secretary*,
66 Third Avenue.

New York City.

Reports of Societies.

PENNSYLVANIA STATE MEDICAL SOCIETY.

Twenty-Sixth Annual Meeting.

[SPECIAL REPORT FOR THE MEDICAL RECORD.]

FIRST DAY, JUNE 9.

This Society met at Pottsville, Penn., on the afternoon of Wednesday, June 9th, at 3 o'clock. One hundred and fifty-five delegates were present from thirty-one counties of the State. The officers of the Society were the following: *President*—Dr. Washington L. Atlee, of Philadelphia. *Vice-Presidents*—Drs. G. D. Bruce, of Alleghany; Rowen Clark, of Blair; P. B. Breinig, of Northampton; and A. Craig, of Lancaster Co. *Permanent Secretary*—Dr. W. B. Atkinson, of Philadelphia. *Assistant Secretary*—Dr. R. S. Cheisman, of Schuylkill. *Corresponding Secretary*—Dr. Richard J. Dunglison, of Philadelphia. *Treasurer*—Dr. Benjamin Lee, of Philadelphia.

After prayer by Dr. Traill Green, of Lafayette College, Easton.

Dr. A. H. Alberstadt, of Pottsville, Chairman of the Committee of Arrangements, welcomed the delegates. Among other matters, he alluded to the fact that, in this land of reputed freedom, but really of quasi despotism, the repeated appeals to legislation have in no instance accomplished the passage of a law, the verbiage of which was not susceptible of an infamous interpretation; and its attempt at execution so besieged by the cry of persecution as to virtually secure an immunity to that class of regular practitioners, whom the law, on the ground of public safety, was intended to apprehend. Physicians, as such, cannot take part in advocating legal measures, without subjecting themselves to the charge of indelicacy by urging restrictions upon men, professing the same avocation, where competition is involved, and thus simply nursing their own pecuniary interests.

He considered that through the county societies, this State medical organization might take such action as would improve the tone and character of the medical schools of the Commonwealth. He then alluded to the local surroundings and the peculiar features of the region in which the State Society was then being held. It has been said, by a wise observer, that the great nations of the near future are those who have the most abundant supply of iron, and of fuel wherewith to reduce it, and it is not a little startling to find that our competitors in the short catalogue of the greatest nations are Russia and China. Assuming these declarations as true, and the importance of coal as one of the great factors of power, Pennsylvania has reason to congratulate herself on the possession of a coal which is the nearest to perfection of any that is known, or likely to be known, being very nearly pure carbon, and spread over the very limited area of four hundred and seventy square miles, less than an average county containing the whole of it. Of this area about one-half lies in our immediate vicinity, but owing to the greater thickness of the beds of coal in our southern coal field, this one-half of the area contains six-tenths of the workable coal. Through this territory the coal lies distributed in sheets, varying in thickness from three feet, at which some red ash veins are profitably worked, up to that grand deposit in the Shenandoah Valley, twelve miles north of us, where the Mammoth vein reaches the thickness of one hundred feet. These

sheets, by changes in the form of the earth's crust since their deposition, have been more or less wrinkled, and are now found standing at all angles of inclination, in some places perfectly flat, and in others, as in the sharp mountains (which form the southern boundary of our town and of the coal region), tilted past the perpendicular, and leaning over into the valley, at depths varying from nothing, where they come to the surface, to the unknown depths just under our feet, where to reach them we should have to descend four thousand feet, nearly three-quarters of a mile below the level of the sea. I will not weary you with enormous figures which represent quantities of which the imagination can take no hold, and will only say, for the comfort of those who know the value of anthracite, and hope it may last their time, that one of our competent observers estimates that at the present rate of consumption the supply should last 2,600 years.

REPORTS FROM COUNTY SOCIETIES.

The next business in order, after calling the roll, was the presentation of reports from County Societies, which were referred to the Committee on Publication. The Corresponding Secretary then reported no correspondence. Delegates for this Society to other State Societies were called upon for their reports, but as usual scarcely any one responded, Dr. Eshleman alone reporting his recent visit to the New Jersey State Society meeting at Atlantic City. He expressed himself as highly gratified at the vigor and zeal of this, the oldest organization in the United States.

The addresses on medicine and surgery were then, on motion, made the first order of business for the next morning; and the various delegations were notified to meet at the close of the afternoon session to select their representatives on the Nominating Committee.

A FEW SUGGESTIONS ON THE USE OF ETHER.

The first practical paper of the meeting was then read by Dr. Atkinson, in the absence of its writer, Dr. O. H. Allis, of Philadelphia, and was entitled "A few Suggestions on the Use of Ether." After alluding to ether and chloroform as the only two anesthetics available to the practitioner, and to the greater safety of the former, its defects being its proneness to irritate the air-passages, its comparative feebleness as an anæsthetic, and its long and vexatious stage of excitement, he inquired whether such defects were not really defects of its mode of administration rather than of the ether itself.

That ether often irritates the larynx is true, says Dr. A., but only in the early stages of the anæsthetic procedure; and that, too, when it is used in too strong and concentrated a form. If a faint odor of ether is given at first, and this gradually increased, it will be found the *exception*, and the *rare exception*, that it is in the slightest degree irritating.

It requires a concentrated vapor of ether to accomplish any prompt results, and those who use it most have learned that it should be used with great profusion, and that the respired air should be thoroughly impregnated with the ether. Such a course has been found to be prompt and to be unattended with danger. I shall offer no criticism upon it, but simply state that I think the effect can be gained quite as promptly and without the *waste of ether*, or the offence to the patient; what other requires is an opportunity to evaporate, and under favorable circumstances, when there there is a thin stratum of it, its disappearance is almost instantaneous. Any apparatus or vehicle for the administration of ether, that holds it in any quantity and retains it in the fluid state, is not well adapted

for its use, while any contrivance that will favor the rapid deliverance of the vapor of ether must, *ceteris paribus*, be more effective.

To reach this point, I have contrived a wire framework for keeping many folds of a bandage at a slight distance from each other, and yet having the whole in a compact form that will readily adjust itself to the face. The sides are enclosed, but the ends are left open;—the one for the patient's face, the other for the entrance of air and the ready supply of ether. It might at first appear unscientific, and to favor a waste of ether, but it is in every way an advantage; not only as it permits the ether to be added in *small and constant quantities*, but as the vapor of ether *falls*, by its density, there can be no need of closing it at the top. The folds of bandage, being separate from each other, cannot hold the ether, and must almost instantly liberate it, and the extent of free exposed surface of bandage, in a space less than four inches square, is over *one thousand square inches*. When one thinks that the air has ready access to both sides of so great a surface, and that upon this surface the ether falls, it must seem rational that such a mode of administration must be effective; and when, too, it is seen that the supply of ether may be constant, *one need never add more than a half drachm at a time*, if he will permit but a few seconds to elapse between the successive supplies. I have found it very effective. I usually produce complete anaesthesia in females in seven minutes, and with about two ounces of ether. Persons seldom object to taking it, and the stage of excitement is no more *excessive, prolonged, or frequent* than with chloroform.

I adhere strictly to the following plan. The patient, being freed from all restraint as to clothing, I place the apparatus over the face and add *a few drops of ether*, hardly enough to give a strong odor of ether. In a few seconds I add a few more drops, taking care not to give it in too concentrated a form at first. In a few minutes I see the patient taking deep respirations, and then I add it more constantly, *not too much, to be offensive or objectionable to my patient, and not too little to be efficacious*. It requires some skill to give ether well, but its safety ought to commend it, and skill will overcome every defect of it.

Dr. W. L. ATLEE stated that formerly he had not been in favor of the use of ether, except when mixed with chloroform, two of the former to one of the latter. The chloroform prevents excitement and the ether counteracts the depressing effects of the chloroform. In his practice he forbids a patient taking food for at least three hours before administering an anæsthetic. The patient is placed in a recumbent position and the anæsthetic administered slowly, so that the respiratory organs grow accustomed to it. Ether alone is never as happy in its effects as when mixed with chloroform. Dr. Allis' instrument was recommended.

Dr. R. J. LEVIs, of Philadelphia, said he didn't think well of any fixed instrument for the administering of ether, and objected to Dr. Allis' instrument on account of its liability to be clogged with mucus, etc., and to injure the face by a rough contact with its hard edges during the stage of excitement.

Dr. PETER D. KEYSER, of Philadelphia, agreed with Dr. Levis. He had given the instrument a faithful trial and discarded it for the old-fashioned towel.

Dr. ATLEE had never seen any of these effects.

The paper of Dr. Allis was referred to the Committee on Publication, by a vote of 40 to 28.

EXSECTION OF ELBOW.

Dr. JOHN J. CARPENTER, of Pottsville, then introduced and explained the case of his brother, whose

elbow had been resected by him in consequence of a very extensive gunshot wound; the result being very satisfactory, with good motion. Amputation had fortunately been contra-indicated by the enfeebled condition of the patient at the time of the operation, which took place within an hour after the accident. Dr. C. was, on motion, requested to write out the details of the case.

Dr. PETER D. KEYSER, of Philadelphia, read a paper on the results of operation in cataract, explaining the signs, etc., employed by oculists, which was referred to the Committee of Publication.

DRS. STETLER, HORTON, and GALLAHER were appointed a Committee on Unfinished Business.

"OLD PHYSIC AND YOUNG PHYSIC."

In the evening, Union Hall was filled with delegates and others, many of them ladies, to hear the address of the President, Dr. Atlee, the subject selected by him being "Old Physic and Young Physic: Some of the Changes of the past Half Century contrasted and compared, and their Advantages estimated." Allusion was first made to the difference of views and habits in regard to venesection. In the practice of Old Physic the lancet was once considered indispensable. It was then the rule to place the patient upright, open a large hole in the vein and allow the blood to flow freely until syncope supervened. Astonishing results sometimes followed, at times symptoms entirely disappearing. At that day every physician carried a spring lancet and used it daily. Now the rule is the reverse. Until the third or fourth decade public sentiment was in full sympathy with the practice of medicine, for people often came to medical offices with their red bandages ready to be bled, sometimes even while in perfect health. In the old practice the blessed, life-giving and refreshing influence of water was denied to patients in fevers. Water and mercurial agents were supposed to be fatally antagonistic.

In the old practice inflammation, rheumatism, etc., were met with the lancet; but by Young Physic they are boldly grappled with by the aid of brandy, old bourbon, etc., and the lancet is discarded. It is questionable whether with these allies Young Physic has been so successful in the treatment of acute diseases as Old Physic with the lancet. He preferred the lancet to the brandy bottle. A happy mean between the two practices was best. The entire giving up of blood-letting was a sacrifice of skill and duty to ignoble fashion.

The progress of Young Physic, and their advantage in the discovery of remedies, especially in female diseases, were next reached. There were many in the audience who could truthfully acknowledge that when they began practice they knew absolutely nothing about certain diseases of women. In the old time scores of female patients went down to the grave unrelieved. The bad effects of the change wrought by absurd fashion in the habits and dress of women were taken up. In proportion as women have departed from simplicity, in that same proportion have their infirmities increased. The confined waist and weighty dress of women were mercilessly ridiculed. Fashionable women were compared to a pea-fowl, strutting the streets and taking a scavenger-like promenade, gathering filth and exhausting strength. The pernicious effect of the fashionable shoe was explained. Nature intended the heel and sole to be on a level, but fashion raises the heel two inches above this level. Woman is thus walking down hill, and as far as health is concerned may be said to be going down hill all the time. The fashionable woman is a burlesque and caricature on nature. If woman's clothing were submitted to a

convention of medical men, or better, of medical women, good results would follow.

Growing out of the ill-health of women is the practice, not sufficiently discouraged by medical men, of using tonics, stimulants, nervines, and opiates, which often ends in ruined lives. The use of stimulants is always hazardous. Permanent strength is the result of molecular nutrition only. Exercise in the open air, cheerful company, and proper dress can alone give back the healthful woman of the past. A terrible responsibility rests on mothers. A London physician asserts that the babies of London are intoxicated from the time of birth until weaned. How far the remark applies to the infants of America the speaker left for others to determine.

The decrease in female death-rate resulting from the discovery of ovariectomy by Dr. McDowell, of Kentucky, was alluded to in eloquent terms of praise; as was also the good effect of the operation of Dr. J. Marion Sims, then of Alabama, for vesico-vaginal fistula.

America was congratulated that one of her sons, a Boston dentist, had discovered the power of ether. The discovery of anesthetics was pronounced the greatest gift any age or country has yet bestowed on suffering humanity. By this means the mitigation of suffering has been inconceivable. He had himself employed chloroform since 1848 without any serious result.

The advantages of Young Physic in the medical uses of the photograph, telegraph, railroad, medical books, museums, etc., were alluded to, as well as the application of instruments to diagnosis, therapeutics, pathology, physiology, etc. He referred to the great diagnostic mark in ovarian tumors discovered by the use of the microscope by Dr. T. M. Drysdale, one of the members of this Society. The clinical thermometer, the speculum of all kinds and uses, the ophthalmoscope, etc.; electricity and its apparatus, gum-elastic and Esmarch's method, etc., were alluded to as part of the later gifts to Young Physic.

He then spoke in terms of praise of the Board of Charities, the hospitals for the relief of the sick and suffering and the insane, and called attention to an institution of recent date and American origin—the Woman's Medical College. He was glad the Society had assumed a proper position in that matter. Woman's fitness for the profession was most emphatically asserted.

The habit of Young Physic of branching out early in practice into a specialty was reprobated. The title of aurist, oculist, etc., implies a more limited knowledge than that of doctor of medicine, and shouldn't be tolerated in the profession.

He concluded by strenuously urging upon the Society the importance of medical organization, the advantage of compliance with the rules of the Code of Ethics, the necessity of laws for the health of the community, etc.

After the conclusion of the address a vote of thanks was tendered Dr. Atlee, and the address was referred to the Committee on Publication. After which the Convention adjourned until the next day.

SECOND DAY, JUNE 10.

THE ADDRESS ON MEDICINE.

The Society reassembled on Thursday morning, and after the announcement of the names of the Committee on Nominations, listened to the Address on Medicine by Dr. William Pepper, of Philadelphia.

After referring to the difficulty of selecting a theme for such an address, from the fact that any report of the progress of medicine was almost rendered unnecessary at this time, so many abstracts, etc., being regularly published in the periodicals of the day, he alluded to the fact that this was the first address of this kind that had been delivered before the State Society for a number of years. He thought it better, therefore, to touch briefly upon a few leading questions of the past decade, which are distinguished for their novelty or originality, rather than to attempt the very slight epitome of all that has been added of importance to medical science during the past five or ten years, or to select any one topic for extensive treatment. Special mention was made of recent important additions to nosology, such as the fact that it was reserved for a Swiss observer, Birmer, of Zurich, in 1872, to detect the very marked peculiarities which characterize certain cases of apparently causeless anæmia, and to describe them under the name of "progressive pernicious anæmia." Since then cases in confirmation have been published by Gressow and others. So large a proportion of these cases have been observed in Switzerland, in addition to the fact that as yet no record of similar cases in France, England, or America have appeared, that it has been supposed that the disease is specially developed under peculiar geographical influences. The peculiar feature of the disease is an intense anæmia, without special cause, so far as yet known, which steadily progresses to a fatal result, often accompanied during the last stages by œdema, hemorrhages, tending to syncope, and characterized anatomically by an extreme diminution in the proportion of the red blood-globules, with no increase in the white cells, and by advanced fatty degeneration of the heart, kidneys, etc., but without any enlargement of the spleen or sympathetic glands. Its pathology, Dr. P. states, cannot be regarded as established, but his own examinations made it probable that the one essential feature is an alteration of the marrow in the bones, similar to that which has now been repeatedly observed in some cases of leucæmia.

It is, however, in connection with the diseases of the nervous system that many of the most brilliant advances in knowledge have been made. One of the most recent additions to the list is Meniere's disease, vertigo labyrinthina. The patient feels a vertigo, and as though the building were falling in, and pitches to the ground, without loss of consciousness. This lasts several minutes, ending with severe vomiting and a copious cold sweat about the forehead, and then he recovers. Ringing in the ear was a constant phenomenon. It is readily seen to be distinct from epilepsy, though no doubt this, even, often occurs. It is the result of otitis, etc., with a lesion of the semicircular canals. Iodide of potassium seemed to give marked relief.

Dr. Pepper next alluded to "pseudo hypertrophic muscular paralysis," sometimes also called "progressive muscular sclerosis," as another addition to the nosology of the day, and after detailing its symptoms, etc., proceeded to discuss the vast field of clinical labor, in which we are making great progress, but in which there is yet so much to be done in this country. No time could be more favorable than this, he thought, for the employment of trained powers of observation, and for the exercise of careful generalization and instruction. Several important additions to our clinical knowledge have been made, not by hospital physicians, freed by their position from the harassing cares of a private practice, and enabled to devote themselves solely to scientific inves-

tigation, but by the practical study and acute observation of the active, busy practitioners in the field of their own private experience. Nor is it a gratifying reflection, that while in the improvement of the mechanical arts our countrymen have shown themselves so apt, so full of inventive genius, we can lay claim to so small a share of the progress effected in medical science during the past quarter of a century. It is humiliating to us as physicians to reflect that next year, when the nations of the earth shall be gathered together in the chief city of our Commonwealth, to witness the proud exhibit of our country's progress in all the arts of peace during the first century of her independent existence, and when we ourselves are to welcome as guests the honored and illustrious representatives of medical science from abroad, to be able to show but little progress or improvement in the great and important field of medical education. But I am assured that if from such bodies as this there shall go forth the demand for reform and advance in our system of education, ere long the need would be fully met, and I may add that the Centennial year will not have passed away before Pennsylvania will have placed herself in the foremost rank in this, as in so many other of the great fields of intellectual progress.

The improved instruments of the day for diagnosis were then explained and exhibited, such as the ophthalmoscope, the thermometer, etc., the various distinctive features of the latter, as manufactured at home and abroad, being demonstrated. Allusion was made to the advantages of studying the action of remedies, especially those of recent introduction, by the combination of experiment with clinical investigation. Digitalis was mentioned as one of those remedies which, on account of its action being more clearly determined by such mode of observation, is now more more intelligently prescribed in affections of the heart, and in other conditions dependent on feeble muscular activity of that organ, and a relaxed state of the terminal vessels. Nitrite of amyl, from its power of instantaneously dilating the capillary vessels, had been advantageously employed in convulsions dependent on spasm of the minute vessels of the brain, in angina pectoris, in epileptic convulsions, etc. Under the head of hypodermic injections of remedies, allusion was made to ergot and its employment in uterine fibroids, aneurism, hæmoptysis, tumors of the spleen, congestive neuralgia, etc. The hydrostatic method of injecting water into the bowels in cases of intestinal obstruction, intussusception, etc., was explained, and cases cited. In some instances, however, abdominal section was required to overcome the difficulty. The methods of paracentesis, as employed in pleuritic effusions and aspiration, were also described, the apparatus being exhibited. In cases of rapid effusion in acute pleurisy, cautious puncture was indicated where the effusion seemed to interfere seriously with the action of the lungs, or to threaten a rapidly fatal result. Sometimes it may be performed to prevent the transition of the case into one of empyema. Various conditions were detailed, in which the operation would be indicated and justifiable, and others, such as the simple, uncomplicated form of acute pleurisy, in which it would be contra-indicated.

He then detailed the results of recent injections into pulmonary cavities, as practised by himself. These were performed with very delicate needles, dilute solutions of iodine or carbolic acid being injected into superficial cavities or into consolidated portions of the lung-tissue. The following were the results of this mode of treatment, which were not complicated with hemorrhage, pleurisy, etc.: In tubercle and acute

casuous infiltration of the pulmonary tissue, no result; subacute, local consolidation probably favors resolution; in chronic, superficial cavity, without tendency to destruction, may be favorable to cicatrization, or diminish the discharge. The injection is to be repeated about once a week, in the proportion of one part of Luzal's solution to ten parts of water, ten to forty-five minims being injected.

The revival of blood-letting and transfusion was then referred to. The condition necessary for the latter operation, its advantages, method, etc., were discussed, and the various forms of apparatus displayed.

The thanks of the Society were voted to Dr. Pepper, as they were subsequently to the authors of other papers presented, all of which were referred to the Committee on Publication.

THE ADDRESS IN SURGERY.

DR. RICHARD J. LEVIS, of Philadelphia, then read the address in surgery, selecting fractures of the lower end of the radius as his theme. After alluding to the prominent symptoms, and the treatment, which was generally less satisfactory than that for fracture of other long bones, cabinet specimens almost always exhibiting marked deformity even after rational treatment. These fractures are generally situated at a quarter to three-quarters of an inch above the articulation of the carpus, measuring from the posterior articular end of the radius. Colles, of Dublin, erroneously located them about three quarters of an inch higher than this, but at this point they present very different features. Barton's observations on fractures of this portion of the bone have scarcely been verified, and the form of fracture, named after that surgeon, must be very rare. It is probable that he mistook for it the ordinary form of transverse fracture which takes place very near the joint. The structure of the bone and its mode of peculiar curvature were described as explanatory of the occurrence of fractures at the lower extremity of the radius, fracture taking place in the middle of the arch formed by the bone. Dr. Lewis advised the employment of a Bond splint, where there is not much deformity, so that the parts may be readily maintained in apposition; but when marked deformity exists, extension will be required in the direction of the long axis, a special form of new and ingenious apparatus for this purpose being exhibited by him.

ADDRESS ON HYGIENE.

DR. BENJAMIN LEE, of Philadelphia, then presented the annual address on hygiene. After alluding to the goddess Hygeia, and her worship as the divinity whose special care it was to bestow and maintain physical health, he referred to the scope of her worship at the present day as comprehending both the preservation of health and the prevention of disease. Included in this last are the various zymotic diseases, which are credited with producing in thirteen of the large towns of Great Britain nearly one-fifth of the whole number of deaths. During five years past, in Ireland alone, five of these diseases have destroyed nearly 60,000 lives. The number of deaths in Philadelphia alone from zymotic diseases during 1873 was 1,550, or 11.25 per cent. of the whole mortality.

The good effects of sanitary legislation in saving human life were illustrated by statistics to show that in London, two hundred years ago, with a population of about 500,000, forty-two out of every thousand died every year, while with a present population of nearly 4,000,000, only twenty-one die out of every thousand of her inhabitants. A similar improvement is noticeable in Paris, even within the past thirty

years. It would be necessary, in order to secure appropriate legislation in this country, to show that a human life has an actual cash value. The last annual report of the Massachusetts State Board of Health, for instance, exhibiting a loss to the State by the sickness of working people alone in that State, at the lowest calculation, of \$15,267,322.00. If one-fifth of this sickness should be preventable, the loss for this class alone would be \$3,000,000.

Dr. Lee then called attention to the action of the American Public Health Association, at Philadelphia, their protest against the establishment of an *abattoir* in a central portion of that city, and the failure of the well-directed efforts of the medical profession and citizens of Philadelphia thus far to prevent the proposed exit. Explanation was then made of a process for the free admission of external air, and its escape when rendered unfit for use, recently introduced into the new buildings of the University at Pennsylvania. After a reference to the merits of salicylic acid as a disinfectant, etc., milk was considered as an agent of absorption and conveyance of the *materies morbi* of disease, and its various impurities and adulterations discussed. Should a State Board of Health be created, one of its first duties should be to investigate the condition of dairies and the mode of transportation of that fluid. Dr. Lee then considered the question of the purity of the water supply. Typhoid fever was stated to be more fatal in the country than in the city, from the fact of the greater impurity of much of the water that is drunk in the country, the water being frequently obtained from the immediate vicinity of cess-pools, house-drains, etc. Recent instances were cited in which the disease was clearly traceable to such causes.

He concluded by offering the following resolutions, which were adopted:

Resolved, That the Committee on Hygiene be, and is hereby authorized to draw on the Secretary for copies of the *Transactions* for the year during which he holds his appointment, and to distribute to same to State Boards of Health, Boards of Health of large cities, the American Public Health Association, and other important sanitary bodies in this country and in Europe, with the request that they will furnish this Society their own *Transactions* and exchange.

On motion of Dr. ATKINSON, the following was adopted:

Whereas, At the session of the American Medical Association, at Louisville, the following resolution was adopted:

Resolved, That each year, until otherwise ordered, the President elect and the permanent Secretary be directed to appeal in the name of the Association to the authorities of each State, where no State Board of Health exists, urging them to establish such Boards. And

Whereas, State Boards of Health now exist in Massachusetts, California, Georgia, Rhode Island, and Michigan, and have fully shown their importance and value; therefore, be it

Resolved, That the State Medical Society do urge upon our State Legislature the importance and necessity of appointing such a board for this State.

Resolved, That a committee of three be appointed to memorialize our State Legislature, and to take whatever steps may be necessary in the matter.

The resolutions were adopted, and Drs. Atkinson and Lee, of Philadelphia, and H. L. Orth, of Dauphin County, were appointed the committee.

Dr. R. L. SIBBET, of Carlisle, then read the report of the Committee on Medical Legislation, showing that the law passed by the last Legislature, in response to

petitions from all parts of the State, was not all that they desired, but the best they could get under the circumstances; its deficiencies might be rendered hereafter by a supplemental law.

THE LATE DR. D. F. CONDIE.

A resolution was then passed in regard to the recent death of Dr. D. F. Condie, and appointing Dr. Andrew Nebinger to prepare resolutions, which were adopted at the afternoon session; and in regard to the distribution of copies of the *Transactions* in the Secretary's hands.

MEDICAL LEGISLATION.

Dr. P. J. ROEBUCK, of Lancaster, then offered the following resolutions:

Whereas, The Legislature of Pennsylvania has in its wisdom enacted a general law to protect the people against incompetent practitioners of Medicine, Surgery, and Obstetrics; and

Whereas, Communities do not generally comprehend the extent of injury to life and inflicted upon them by incompetent practitioners; and

Whereas, Laws are of no avail unless enforced, therefore.

Resolved, That the members of State medical and various local societies, to protect the life and health of the people against empiricism, should make a determinate effort to enforce the law passed last winter, entitled, "An Act to regulate the Practice of Medicine, Surgery, and Obstetrics in the Commonwealth of Pennsylvania."

On motion of Dr. JOHN L. ATLEE, the subject was referred to the county societies, who should appoint committees to insure the enforcement of this law. The Society then adjourned until afternoon.

After reassembling at 2.30 o'clock, a note was read from Professor S. D. Gross, regretting his inability to be present.

ON MENTAL DISEASES.

Dr. JOHN CURWEX, of Harrisburg, then read an address on Mental Disorders which was full of practical suggestions, and among other items of interest severely criticized the present methods of school education, in which quantity rather than quality seemed to be the desideratum in the schools. But little attention seemed to be paid to the capacity of the pupil, and the foundation was thus laid for mental disorders. Cases were also cited in which the tendency to crime seemed to be inherited from some vicious propensity of the mother.

The paper excited much discussion, and on motion of Dr. John L. Atlee, Dr. Curwex was requested to furnish that portion of his address relating to the subject of education to Mr. Wickersham, State Superintendent of Schools, for publication in the *School Journal*, and to the Board of Education of Philadelphia.

OFFICERS FOR THE ENSUING YEAR.

The Committee on Nominations reported the following officers:

President, Crawford Irwin, of Blair Co. *Five-President*, Andrew Nebinger, Philadelphia; A. N. Naebertstadt, Schuylkill; R. L. Sibbet, Cumberland, and J. F. Ross, Clarion. *Corresponding Secretary*, Horace Y. Evans, Philadelphia. *Permanent Secretary*, Wm. B. Atkinson, Philadelphia. *Recording Secretary*, James Tyson, Philadelphia. *Treasurer*, Benjamin Lee, Philadelphia. *Committee of Publication*, Drs. Atkinson, Evans, Lee, Drysdale, Tyson, Fricke, and McIntire. Delegates were also appointed to other State and National Societies.

The President then announced the following appoint-

ments: Address in Surgery, Dr. D. Hayes Agnew, of Philadelphia; Address in Obstetrics, Dr. R. Davis, Wilkesbarre; Address in Medicine, Dr. J. Aitken Meigs, Philadelphia; Address in Hygiene, Dr. B. Lee, Philadelphia; Address on Mental Disorders, Dr. John Curwen, Harrisburg.

Dr. C. F. Deshler, Delegate from the New Jersey State Medical Society, was then introduced and made a few felicitous remarks in regard to the nature of the information which he should take back with him to New Jersey.

CLOSURE OF EUSTACHIAN TUBE.

After the transaction of various items of general interest, Dr. L. Turnbull, of Philadelphia, read a paper on "Closure of the Eustachian Tube from thickening of the Mucous Membrane." When this thickening becomes excessive, he employs the Eustachian forceps devised by him for the direct application of astringent and alterative remedies. A new method was suggested for the examination of the opening of the tube in the pharynx with the finger.

Among other items of interest, the report of the Commission on the condition of insane criminals to the last Legislature, with plans for the construction of a hospital, was presented by Dr. Curwen, and referred to the Committee on Publication. A Committee was appointed, on motion of the same gentleman, to memorialize the Legislature for the construction of a new general hospital for the insane in the Eastern Counties of the State.

The subject of typhoid fever was then discussed with much earnestness, in consequence of the reopening of the subject as introduced in Dr. Lee's paper on hygiene.

Dr. EVANS being ineligible as Corresponding Secretary, on account of his absence, Dr. Thomas M. Drysdale was appointed to that position.

Dr. ALLIS, of Philadelphia, then reintroduced the apparatus devised by him for the administration of ether, and practically illustrated its efficiency in his hands upon a subject introduced for that purpose. A committee of three was appointed to report at the next annual meeting on the most desirable methods of administering anaesthetics.

On motion of Dr. Stetter, of Philadelphia, resolutions were adopted encouraging the formation of County Medical Societies throughout the entire State in time to participate in the meeting of the Society to be held during the centennial year.

After the usual resolutions of thanks, etc., and the introduction of the President elect, the Society adjourned, to meet in Philadelphia on the last Wednesday in May, 1876.

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting, May 28th, 1875.

DR. BAYLIS, VICE-PRESIDENT, in the Chair.

REPORT ON DERMATOLOGY.

In compliance with an established regulation of this Society, that the last meeting of each month shall be devoted to a report upon some medical subject, Dr. GEORGE HENRY FOX presented a paper in which, in a general way, he considered the present condition of Dermatology. The pathology of only a few subjects was referred to; the treatment received only a brief consideration, and the bulk of the report was made up of the floating views held regarding the essential na-

ture of these lesions. The advanced position which the science of dermatology at present occupies was attributed to the microscope, and when it comes into general use, and not until then, will the proper degree of success be attained in the treatment of this class of diseases.

With reference to the pathology of *lupus*, the views of Friedlander alone were presented, who holds that it is essentially a localized tuberculosis.

The most important question in connection with dermatology was considered to be whether these skin lesions are essentially of constitutional origin, or are simply local in character. The views held by French, German, and English authors of acknowledged authority were referred to at some length.

One external application was alluded to which has lately been recommended, namely, gurjun-oil. This oil is an oleo-resinous substance, obtained from India, and was reintroduced to the profession in 1873, by Dugal, in the treatment of leprosy in that country. He used it in combination with lime-water, equal parts, and it has latterly been used by Dr. Erasmus Wilson in the treatment of eczema, lupus, and cancer. He has ascribed to it the valuable property of relieving pain in these affections.

In the discussion which followed the reading of the paper—

Dr. R. W. TAYLOR advocated the doctrine that local causes are largely prolific in the production of skin lesions. Internal causes may be at the base of some cases, but in a vast majority, perhaps in two-thirds of the entire number, the lesion is of external origin. He proposed to read a paper at some future date, in which he should discuss this question *in extenso*.

Dr. PIFFARD commented at some length upon the pathology of lupus, and brought forward the fact that scarcely any two observers agree upon this point. He regarded the pathology of this disease as by no means settled. Passing to the essential nature of skin affections, he argued that they are in most cases of constitutional origin, and that the skin disease is an outward manifestation of a constitutional state. He was of the opinion that the diathesis upon which skin diseases depend is not so vague and uncertain in its nature as many are inclined to suppose.

Dr. McILVAINE looked with incredulity upon the theory of an acid and alkaline condition, and the presence of certain heterodox materials in the blood.

After a vote of thanks to Dr. Fox for his able report, the Society adjourned.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from June 13th to June 19th, 1875.

HASSON, A. B., Surgeon.—Granted leave of absence for twenty days. S. O. 121, Military Division of the Atlantic, June 15, 1875.

STEINMETZ, W. R., Assistant Surgeon.—Assigned to duty at Cheyenne and Arapahoe Agency, Indian Territory. S. O. 91, Department of the Missouri, June 8, 1875.

SKINNER, JNO. O., Assistant Surgeon.—Assigned to duty at St. Augustine, Fla. S. O. 79, Department of the South, June 14, 1875.

CHARITY HOSPITAL.—Dr. Montrose A. Pallen has been appointed Attending Surgeon to Charity Hospital, in place of Dr. J. J. P. White, resigned.

THYMOL.—The formula for thymol is $C_{10}H_{14}O$ and not $C_{10}H_{14}C_2$ as stated on page 423 of our last issue.

Original Communications.

ON SUBPERIOSTEAL RESECTION OF THE
TIBIO-TARSAL ARTICULATION—PAR-
TIAL AND TOTAL, PRIMARY AND
SECONDARY.

By A. ROSE, M.D.

NEW YORK.

SUBPERIOSTEAL resections of joints were performed on dogs as early as 1830, by Dr. B. Heine, of Wurzburg. A large number of valuable specimens prepared by Heine are now in the Museum of Anatomy in Wurzburg. By means of these it has been proved that each joint of the canine skeleton can, after subperiosteal resection, be perfectly restored in its form as well as its function. Whereas, upon removing the ends of the bones which constitute a joint, together with the surrounding soft parts (capsule, periosteum, and ligaments), Heine found that no regeneration of the joint took place, and that only a false joint was the result.

The results of these experiments, communicated in 1834 by Heine to the Paris Academy of Medicine, caused Flourens and Ollier to make similar experiments, by which the latter proved the osteogenous function of the periosteum.

Langenbeck, having in 1840 inspected Heine's specimens in the Wurzburg Museum, was induced to perform subperiosteal resection on man. His first resections were made in 1842 on the joints of the finger, when he extirpated entire bones [not necrosed], and removed portions of bone, leaving the periosteum intact.

Frank H. Hamilton, at that time professor in Buffalo, discovered and described—quite independent from Langenbeck or any one else—reproduction of a whole phalanx after subperiosteal resection. The following is an extract from the *Buffalo Medical Journal*, Vol. V., 1849:

"Catharine Dolen, aged 24, admitted December 25, 1849. Thumb. The bone was necrosed, and on the 29th I extracted the phalanx entire. The inflammation having considerably subsided by the 3d of January, five days after the operation, I applied a tape roller the whole length of the thumb, and moderately tight. This was continued in intermissions during two months, when a new phalanx was found to have been formed of the same length, and breadth, and form as the original phalanx; the articulating surface was also reformed, and the flexor and extensor tendons so attached as that the motions of the joint were perfect. . . . It is the complete reconstruction of a bone when it has been removed in its totality by extraction that excites our surprise, and which we have marked as a novelty."

In the year 1850 Dr. Hamilton reported this case to the American Medical Association, and we find it in the *Transactions* of this society, in Vol. III., page 355. About at the same time Dr. Dudley described the same subject.

Langenbeck first attempted subperiosteal resection of a large joint in 1859, when he removed the head of the right humerus on account of caries. The specimen, which is preserved in the collection of the Klinikum in Berlin, represents the first case of a complete regeneration of the shoulder-joint after resection of the head of the humerus in man. On May 30th of the

same year he made a subperiosteal resection of the tibia and astragalus of the Russian Lieutenant-General v. Kwizinsky, aged 68 years, who was wounded in the battle of the Alma in 1854.

The first subperiosteal resection of the ankle-joint in the field was made by Langenbeck, on the 1st of May, 1864. The wounded soldier, a drummer, was about to suffer amputation at the upper third of the leg, when Langenbeck was requested by the commanding General to leave no means untried to preserve, if possible, the leg of a soldier who distinguished himself in storming the Duppel (Denmark) fortifications. Langenbeck resected the ankle-joint only in such cases, where otherwise amputation of the leg was unavoidable and positively indicated.

Subperiosteal resection of the ankle-joint Langenbeck defines to be: severing of the fibrous layer of the epiphyses of the tibia and fibula, together with the ligaments attached to the articular ends of the bones, the separation of the periosteum from the bone, and the preservation of the interosseous membrane, whenever resection must be extended over a large surface.

This operation is called in Germany the typical resection of the ankle-joint, although it ought to be more properly designated as "*Langenbeck's operation*."

All resections of the ankle-joint made previous to Langenbeck's operations were either extractions of bone splinters or the removal with the saw of irreducible extremities of the bones protruding through the skin in compound fractures and luxations, to which class belong especially the well-known operations of Sir Astley Cooper. At any rate there are no subperiosteal operations recorded before Langenbeck's time.

Although our experience about this operation comprises only a period of fifteen years, yet it is already an acknowledged fact, that the results obtained so far are exceedingly favorable, more so than in the resection of any other joint.

The union which takes place, after resection, between the bones of the leg and foot becomes so firm that the limb is able to bear the weight of the entire body.

A more abundant reproduction of bony tissue was observed at the ankle than at any other joint (after the removal of the lower extremities of the tibia and fibula), and by the tibia especially do we find this principle of regeneration possessed in a high degree. Even after an extensive resection of this bone a new, solid, and broad epiphysis, with malleolus, is formed, and the shape of the ankle-joint is hardly changed in appearance, if sufficient time has passed after resection and after a surplus portion of the callus has been resorbed, while the shortening caused by the operation is reduced to about one-fourth of that resulting from the other method of resection. Frequently the entire shortening amounts to but a few lines, or may even be entirely absent. Thus very large portions of the tibia and fibula may be taken away, without depreciating the usefulness of the limb.

Our knowledge of the growth and regeneration of bone to-day points to the preservation of the periosteum as the principal agent in these processes. According to Langenbeck some other agencies probably enter into this function. Possibly the ligaments retained, together with the fibrous layer, and certainly the interosseous membrane, cause the abundant formation of bone. This strong interosseous membrane, extending between the tibia and fibula, from the upper to the lower epiphyses, is evidently similar to the periosteum, and is, like it, likely to undergo ossification, as it is sometimes in a morbid state found to be changed into

an osseous plate. It is exceedingly important in resecting to retain this membrane, so as to have an additional source whence bone may be reproduced.

The fact of there being neither muscles nor tendons attached to the lower extremities of the tibia and fibula renders resection at the ankle-joint especially favorable and certain.

In the above-mentioned first case of resection of the ankle-joint, performed by Langenbeck in the field on May 1st, 1864, the lower third of the fibula being fractured in three places, this portion of the bone was resected to the extent of seven centimetres; the shattered upper surface of the astragalus was removed next, and finally the lower end of the tibia, having been broken into several fragments, was sawed off to the same extent as the fibula. The patient has been, since the end of December, 1864, a servant in the royal household; in this capacity he has to go up and down stairs many times a day, to walk rapidly over exceedingly smooth floors, and often to remain standing for a long time, all of which he does with the greatest ease and without any especial fatigue. The configuration of the joint has in the course of time become perfectly normal.

I shall relate briefly but one more of the glorious resections performed by Langenbeck. On July 29th, 1864, he resected a piece of the tibia measuring eleven centimetres. The patient, a Danish lieutenant, visited Dr. von Langenbeck in Berlin in 1873, having just returned from a pedestrian tour in Switzerland, where he had ascended, in common Alpine shoes, Mount Rosa. His walk was perfectly normal, while the *shortening amounted to but three centimetres*.

I cannot but relate the remarkable case of Professor Volkman, which illustrates how much a resected ankle joint is able to stand and to perform. The patient, M. S., a young girl, was attacked at the age of twelve years with hemiplegia of the left side (paralysis of the face, arm, and leg), beginning with anesthesia of the left little finger, and terminating after ten to eleven days in complete hemiplegia. Her mind was not disturbed; there was no fever. The attending family physician felt justified in ascribing the affection to hereditary syphilis. During the first months of medical treatment the paralysis of the face improved considerably, that of the leg a little, the patient being now able to move the toes somewhat, but the arm remained entirely paralyzed. The patient still continues in the same state. About nine months after the attack, in the spring of 1869, as alleged in consequence of a sprain, there appeared on the right tibia, close to the ankle-joint, a firm elastic swelling of a gunnatus nature. After remaining inert for one year, this swelling broke and became an ichorous ulcer, at the bottom of which the bare and necrosed bone could be seen. A perforation into the ankle-joint suddenly occurred in the beginning of May, 1870, causing suppuration of the joint. Prof. Volkman, having been called in consultation, found the child very much reduced with a high fever, the ankle-joint useless and dangling in consequence of the destruction of the ligaments and cartilage, a profuse and ill-smelling suppuration, and purulent canals extending along the inner side of the calf of the leg. May 16th, 1870, resection of the joint was practised by the removal of an inch of the tibia, and thorough scooping out of the astragalus with a sharp spoon. In September every wound was closed; the patient, however, had to wait until December before making a serious attempt to walk; but she finally obtained nearly the full use of the resected joint. At the present time the foot can be flexed and extended to a normal degree. The motions of the foot are strong and sure, the patient using neither a cane nor any other support in

walking about all day; while the entire weight of the body rests almost exclusively upon the right foot, the left foot being useless on account of the paralytic state. No visible shortening has taken place. The shape of the ankle is so perfect that if a thin stocking is put on nobody suspects that such an operation has been performed. Concerning this case Volkman makes the following remarks: "On witnessing an extensive resection of the ankle-joint for the first time, and perceiving that, immediately afterwards, the foot is united to the leg merely by the thin walls of a hollow cylinder, formed by the soft parts of the joints, and deprived of every firm support, one is struck with admiration at the enormous recuperative power of the human body by which such deep injuries can be redressed and redeemed."

The rate of mortality after resection is remarkably small, and the number of failures insignificant. According to Stauff's statistical tables, published in 1872, out of 104 cases, a really useful limb was obtained in more than 75 per cent.

As a first indication for a resection of the ankle-joint is to be mentioned an open wound of the joint. In compound fractures and luxations of the ankle-joint, with great lesions of the soft parts, and protruding bones, resection is urgently demanded. This indication has already been mentioned by Celsus: "*Illo quod excedit, abscindendum est.*" Sir Astley Cooper especially recommended and performed resection with very brilliant results in compound luxations. Dr. F. H. Hamilton called especial attention to the value of resection in compound dislocations, in the first edition of his book on Fractures and Dislocations (1860), where he cited a case of compound dislocation of the ankle-joint in which he practised resection, to illustrate its advantage. On January 21st, 1875, I saw Dr. Hamilton, at his clinic in Bellevue Hospital, resect two inches of the lower end of the tibia in a case of compound dislocation of this bone. The patient was a young woman. The injured limb had been under the so-called expectant treatment for some time, had become the seat of phlegmonous inflammation, and was now in a most precarious condition. In a consultation, held before the operation was made, the question of amputation or resection had been raised, and the votes for the one and the other were equally divided. The patient, after resection had been performed, did exceedingly well; the foot is now perfectly in line and position, and complete recovery is assured.

As the sawing off of protruding bones does not belong strictly to methodical resections of the joints, it may be briefly mentioned that it is far preferable to the so-called conservative treatment. It is known that the rate of mortality after the latter method is not small. A large number die of pyæmia or septicæmia, while others have to submit to secondary amputation with or without success.

Compound fractures, with perforated joints, are caused principally by bullets. In referring to the classical writings of Hueter and Langenbeck on this subject, I may be permitted to quote part of the former's work on diseases of the joints:

"In traumatic suppuration, with accompanying injury to the bone, incisions for the purpose of giving an outlet to the discharge are generally insufficient. The relations of the bones forming the ankle-joint are so simple that a discharge of pus through an incised wound would not be prevented to any serious degree; but a lesion of the bones makes a very unfavorable change in the conditions. A broken malleolus drawn away from the articular surface of the astragalus by

its ligaments, forms a little canal from which no incision can get a free flow of pus. Worse still are the fissures of the injured bones, which are rarely absent in perforating gunshot wounds of the tibia. In these the secreted matter collects, and thus maintains the suppuration of the joint even after an incision has been made, while rendering osteo-myelitis of the tibia possible as a sequence. Under these circumstances no reliance can be placed any longer upon a simple incision, which ought to be discarded for the safe method of resection."

It must not be understood that the conservative treatment of a gunshot wound of the ankle-joint is to be excluded. Langenbeck remarks most emphatically that it must be considered to the fullest extent, and that even such cases, where the ball passed right through the malleoli and the astragalus and fractured these bones, can be healed by an early incision and extraction of bone splinters. Resection, however, ought to be performed in a considerable number of cases instead of amputation of the leg.

I take this occasion to report a case of compound fracture of the malleolus internus which happened in my own practice.

W. Krause, 48 years old, born in Germany, single, farmer, was injured by a horse stepping on his foot; he received a fracture of the lower third of the right leg, with a compound fracture of the malleolus internus, which latter opened the joint. The attending physician placed the injured leg in a fracture-box, where it was kept for six weeks, and then had it kept quiet for five weeks longer. During this period both legs, as I was told, were attacked by phlegmonous inflammation, which was treated by incisions. In the injured joint, according to the patient's description, a synovitis hyperplastica granulosa had been aroused, the proliferous granulations of which were treated with caustic applications and then covered with adhesive plaster.

On August 29th, 1874, the patient was first seen by me. He had been living in the country, and was admitted to the St. Francis Hospital. The general health of the patient, who had been a robust man, was very bad. He was feverish; both lower extremities were œdematous. The fracture of the tibia and fibula was united; the foot, however, turned outwards in consequence of the destruction of the capsule and the ligaments. A portion of the superficially necrosed internal malleolus protruded from an ichorous, sanious wound. Resection of the joint was proposed to and accepted by the patient. Until the day of the operation, which I performed on September 2d, 1874, with the kind assistance of Drs. J. Simrock and B. Scharlau, the injured limb was placed in a warm water bath. As no serious hemorrhage was likely to be expected, I did not apply the elastic bandage of Esmarch, especially since this would have promoted the venous flow in an œdematous limb just taken out of a warm water bath.

The resection of the internal malleolus was made according to Langenbeck's method, which will be described hereafter. The periosteum being considerably thickened was easily separated from the bone, and was fully preserved. After the removal of the internal malleolus it was found that every other bone belonging to the joint was in a healthy state, in consequence of which the articular extremity of the tibia alone was removed. The piece thus removed measured $1\frac{1}{2}$ inches. On the day following the operation the limb, properly fixed, was again placed in the warm water bath. On September 10th, Dr. Scharlau kindly applied a plaster-of-Paris bandage with Volkman's splint.

The cavity of the wound was soon filled with gran-

ulations, and was perfectly closed. On October 6th the first bandage was then removed and a more simple and lighter one applied.

On October 9th the patient complained of pain at the point of resection. After cutting a fenestra through the bandage, a small abscess was found and opened, when the pain subsided. In the course of the treatment the patient suffered occasionally from pain, which, however, was always found to be caused by an inconvenient position of the limb. The last plaster bandage was removed at the end of October. He remained in good condition until the 11th of November, when I resigned my position in the hospital. I was informed that on November 17th another abscess was suspected at the point of resection. An incision was made, a cataplasm applied, and the wound filled with lint. The patient, however, states that no pus, but merely "a watery liquid," was discharged. I next heard that the physician who then attended the patient at the hospital said that necrosed pieces of bone were still in the wound, and that, to my great astonishment, he proposed to amputate the foot on November 22d, at 2 P.M.

The patient, not acceding to the proposition, left the hospital on November 29th, and placed himself again under my care. I saw him for the first time, after I had left the hospital, on December 1st, when I found both lower extremities œdematous and a wound over the right malleolus internus nearly healed, but no sign or symptom of caries or necrosis, nor has any disease of the bone been observed down to the present time (March 27th, 1875). The cold and warm douche was alternately used upon the resected limb; electricity was also applied. Rubbing the limb with cold water was found especially useful. On January 3d, the patient was able, with the aid of sticks, to walk through the room; he also tried successfully, and without giving him any pain, letting the weight of the entire body rest on the resected foot. The patient then improved steadily, and on March 26th I had the honor to present the patient at a meeting of German physicians at the residence of Dr. A. Jacobi.

The resected malleolus was formed anew. The astragalus is united firmly to the bone of the leg by bony ankylosis; the longitudinal axis of the foot forming a right angle with the leg; the sole of the foot touches the ground, and stepping on the foot causes no pain. The gait is firm and secure; he needs no support, and is able to stand for a long time on the resected foot, while he lifts the other foot easily off the ground. He ascends stairs without any difficulty. On March 27th, he left New York to go to work on his farm.

A case operated on by Dr. E. Krackowizer belongs also to this category.

R. B., wireworker, at the time 36 years old, received, in consequence of a fall off the sidewalk on May 11th, 1868, a dislocation of the tibia forward; the articular end being thrown forward over the astragalus, consequently bringing the foot in posterior luxation. The force of the dislocation also caused a fracture of malleolus from above and behind, downward and in front. The engraving, made from a plaster cast, illustrates this unusual injury.

The patient fell into the hands of an irregular practitioner, who kept the injured extremity for ten weeks in a fracture-box. Dr. K. saw the patient in the beginning of August, 1868, when he found the limb in the condition described above. After an unsuccessful attempt to reduce the dislocation, resection of the internal malleolus was made on August 17th to the extent of two inches, splinters of bone from the pos-

terior portion of the malleolus being also removed. The resection was not made subperiosteally, and as no malleolus was formed, there is accordingly a shortening of the limb. The man is, however, able to walk by means of a high heel.

Injuries of the ankle-joint, by means of cutting or stabbing instruments, are of rare occurrence. I can speak of such injuries from my own experience only in other joints, especially the knee-joint. As soon as a joint has received a stab wound in a certain direction synovia escapes; suppuration of the synovial membrane may follow, causing in the larger joints, like the ankle joint, violent local and general symptoms. If infecting substances find their way into the synovial cavity, the heretofore healthy pus becomes ichorous and life is threatened, and the question is, "*Resection or amputation?*"

The same holds good in relation to incisive wounds. Although even in such injuries the wound may heal per primam intentionem in spite of the great irritability of the synovial membrane and the entrance of air into the articular cavity, yet the danger of the most violent inflammation of the joint is greater in incisive than in stab wounds.

Next to open wounds of the joints with or without injury of the bones, simple fractures of the bones might, in consequence of improper or negligent treatment, necessitate resection. It sometimes happens that in fracture of a malleolus or the malleoli no firm bandages are applied, but rather popular and useless liniments; the patient also tries too soon to walk, thus preventing a firm union of the bony fragments or their ligamentous connections. The foot then turns outwards, a "*pes valgus traumaticus*" ensues, and resection becomes the only remedy for its correction.

In coexisting suppuration of the joint and caries with general symptoms threatening the patient's life, resection or amputation must be decided upon.

Serious forms of articular inflammation may follow simple injuries, like a contusion, in consequence of neglect or wrong treatment.

In young subjects, especially those afflicted with a scrofulous or tubercular diathesis, a slight injury may be the cause of synovitis; sometimes an inflammation occurs spontaneously without any traumatic cause. We have in such cases frequently that form of synovial inflammation designated by Hueter "*synovitis hyperplastica granulosa*," or according to the old nomenclature,

"*tumor albus pedis*." Billroth calls this affection the fungoid inflammation of the joint, from the occurrence of spongy swellings of very soft vascular and new connective tissue. The continuation of the synovial inflammation to the bone itself happens, according to Hueter, much sooner and more frequently than is generally supposed. Especially is the lower spongy portion of the tibia subject to diffuse, and less often to a partial, osteo-myelitis, while the primary affections, synovitis and chondritis, may, at the same time, be of a slight nature. Hueter saw patients who had not walked for years on account of the tenderness of the tibia, where after resection not only no suppuration was found, but only a very moderate granular proliferation on the synovial membrane.

In other cases of granular proliferation, collections of pus and articular fistulae may be formed, followed by phlegmone extending up the leg. The entire constitution of the patient is affected, life is threatened, and the same symptoms as described before in the case of compound fracture forces the surgeon to choose between resection or amputation.

I want to add here that according to Dr. Hamilton's and my own experience the warm water bath is the best treatment for all chronic inflammation, and especially when the ankle-joint is attacked, as it promotes resorption of the connective tissue formed on synovial membrane and of the hydroptic synovia.

Hueter is convinced that *resection of the ankle-joint is indicated whenever granular synovitis passes into suppuration*. He considers incisions, formerly recommended, at this stage useless.

Agreeing with this opinion, I should decide upon early resection. I observed in two cases of conservative treatment of hyperplastic granular synovitis a constant sinking of the patient. In one case amputation was performed at a late period, while the other was not operated upon. Both cases terminated fatally.

Most surgeons differ in opinion as to the advisability of resection of the ankle-joint on account of caries. The experience of Langenbeck has been rather unfavorable, for in eight cases operated on by him there was not even one successful.

In England resection of the ankle-joint on account of caries is looked upon unfavorably, many surgeons preferring amputation.

Hueter, however, claims to have been very successful, having performed resection in seven cases of disease of the ankle-joint with the best results in the clinic of Greifswalde, in two of which there was a movable joint with a formation of new malleoli. He was then convinced that resections of the ankle-joint, undertaken on account of organic disease, were quite as successful as those for the relief of injuries of traumatic origin, if properly performed and on proper indications.

Further experience must be looked upon with deep interest.

In deciding upon the advisability of this operation, the principal question will be, whether the local affection is an idiopathic disease, or the result of a constitutional sickness, and it will be impossible to ascertain this, whenever the physical examination furnishes only negative results.

A general or constitutional affection is to be excluded in cases where no cure follows resection, while a subsequent amputation heals easily. Langenbeck is of the opinion that local causes prevent the process of healing after resection of the ankle-joint in pathological cases. Having performed resection in a large number of cases of the shoulder and elbow-joint, he

has never been obliged to make a secondary amputation; although several patients died after some years from tubercular disease of the lung, yet resection had been successful. He explains these contradictory results, on the ground that in most cases there exists in the lower epiphyses of the tibia and fibula a more intense susceptibility to disease.

According to Hueter, certain cases of "floating bodies" in the joints might be proper subjects for resection, not secondary resections in consequence of suppuration, but primary operations. He performed resection of the ankle-joint in a case which showed every symptom of a floating body, although he was unable to ascertain its actual presence until after the operation, when there was found a small body of the size of a pea attached to the posterior margin of the astragalus. The patient had been for some time unable to walk. The result was satisfactory.

Concerning the question of primary or secondary resection of the ankle-joint, experience teaches that primary resection ought to be undertaken in all cases of compound fracture and dislocation, with large wounds and protruding bones.

Although Volkman points out the generally believed view, that the functional result of a late resection is decidedly more favorable on account of the better formation of bone from the inflamed and indurated periosteum, yet he believes that an early operation, in all cases of *severe* destruction of the lower epiphysis of the tibia by gunshot, is the only means of reducing the mortality of these injuries and of avoiding the necessity of amputation.

According to Langenbeck, however, it is advisable to defer primary resection whenever the ankle-joint is destroyed by balls of a heavy calibre, keeping the joint in the meantime perfectly immovable and the wound open until the proper time arrives for secondary resection. In three cases of gunshot wounds of the ankle-joint, where all the three bones of the joint were injured, he applied, a few hours after the injury was received, a plaster-of-Paris bandage, and succeeded in obtaining an ankylosed joint and a useful foot. He points out the danger of primary resection in such cases of operating upon parts which might be threatened with necrosis on account of the injury, whereas, in secondary resections, a better judgment can be obtained of the condition of the several bones forming the joint.

As to my own experience in primary resection, I would refer briefly to a subperiosteal resection performed on a boy seven years old. I removed the clavicle on account of dangerous supra- and intra-clavicular abscesses complicated by periostitis. I first took away the outer half with the acromial extremity at a time when the bone itself was not yet affected, removing after a few weeks the inner half with the sternal extremity, which in the meantime had become necrosed. A new bone was formed, consisting of two portions connected by a fibrous mass. The patient could use his arm perfectly well. I presented this case in February, 1875, in Dr. Hamilton's clinic, and at a meeting of German physicians at Dr. Jacobi's residence.

Concerning the question of partial or total resection of the tibio-tarsal joint, a great difference of opinion is entertained among the surgical authorities. Hueter says as follows against partial resection: "Although I do not consider partial resection, especially the retention of the astragalus, a faulty operation, still I must express myself decidedly against the partial resection of this joint. The retaining of a malleolus must necessarily interfere with the

prompt escape of pus from the cavity left after resection, which might result in phlegmonous inflammation and suppuration along the tendons and their respective sheaths. The retention of the astragalus is not accompanied by the same unfavorable results; it may, however, retard the healing process in a different manner. The astragalus is in most cases still covered by remnants of its cartilage, which may even in some cases be intact. This cartilage must either slough off or be covered by connective and granular tissues. In the latter case the newly formed bone tissue of the tibia is not united to a homogeneous substance growing from the astragalus. A firm union between the tibia and astragalus is delayed, and in consequence the intention of the operator—the securing a serviceable foot—rendered doubtful, and may even be completely defeated by obtaining a too movable joint. On the other hand, partial resection will offer no advantage, except making the operation somewhat less difficult. It will be best, on the whole, not to undertake a partial resection of the ankle-joint."

Langenbeck expresses the following opinion:

"My experience proves that both partial and total resection of the ankle-joint can be equally successful. If further operations confirm my views, it will be safe to resect in all cases as *little of the joint as possible*, as the after-treatment is easier in partial resection, while a shortening of the limb will also be more surely avoided than after the removal of large sections of bone, or of the articular extremities of all the three bones entering into the formation of the joint. A malleolus left in its place will prove a valuable support for the foot, render the application of bandages and other more elaborate contrivances more convenient, and indicate more plainly the length the limb ought to have; then the empty bag formed by the soft parts after a complete removal of the bone. In making resection of the ankle-joint I have always observed the following rules, an examination of which I desire the profession to make:

"1. *In caries of the ankle-joint*, with few exceptions, I always resected both malleoli and the superior articular surface of the astragalus. If deep-seated disease existed in the latter bone, I have removed it almost entirely with chisel or sharp scoop.

"2. *In fractures from gunshots of both malleoli and of the astragalus*, with considerable destruction of these bones, I have always performed total resection, leaving, however, occasionally the lower portion of the astragalus intact.

"3. *In a fracture of the internal malleolus alone* caused by a gunshot, I have resected *only the lower extremity of the tibia*, leaving the other two bones intact.

"4. *In a fractured fibula* I have, with one exception, always removed the *external malleolus with the superior articular surface of the astragalus*, although the latter bone was not injured.

"5. If the three bones were injured, while *one malleolus was simply fractured* without being broken into fragments, I have always left it in place.

"6. In an extensive fracture of the astragalus with the ball still remaining, I have extirpated the entire bone without removing the uninjured malleoli."

The practicability of partial resection has caused a good deal of discussion. Dr. L. Meyer (*Deutsche Zeitschrift für Chirurgie*) is utterly opposed to it, and cites a number of prominent surgeons in confirmation of his opinion. Having at a meeting of German physicians in this city spoken of partial resection of the great toe in hallux valgus, great surprise was manifested by one gentleman present at the favorable results obtained by Dr. Hamilton and myself, as they

were so utterly at variance with the theory advanced by Dr. Meyer in his essay. I am of the opinion, however, that experience is decidedly in favor of partial resection whenever it is indicated.

The success of the operation with regard to life and future usefulness depends largely upon the manner of its execution.

Langenbeck's method is generally adopted as the best, being practicable in every case and saving the tendons.

Resection of the fibula is first undertaken. For this purpose the foot is placed with the inner side upon a firm pillow. An incision 2-3 inches long is then made along the middle of the bone down to the point of the malleolus, cutting deep enough to sever also the periosteum. After reaching the malleolus, the incision is carried one-third of an inch further, cutting, however, merely through the skin, in order to save the tendons passing around the malleolus, and to facilitate the removal of the bone. The portion of fibula which is to be removed is next separated from the periosteum by means of the periosteal elevator, and then sawed off with the straight narrow saw. The index-finger of the left hand or a spatula is kept in the interosseous space in order to keep the soft parts from being injured by the saw. The bone is not sawn directly across, but in a somewhat oblique direction, by directing the edge of the saw a little towards the joint, thus facilitating the complete removal of the malleolus. The portion thus sawn off is removed by seizing its upper end with Langenbeck's resection forceps, or with a strong, sharp hook; and by gently rotating it, it is disarticulated with the aid of the knife and elevator. After this, the most tedious part of the operation is done, the foot is turned and placed upon its outer edge. Another incision similar to the former is then made along the inner side of the joint down to and through the periosteum, carrying the incision also superficially below the internal malleolus. The portion of the tibia about to be removed is sawn off in the same manner and removed like the fibula, by disarticulating it and separating it all around from the periosteum. The firm ligaments attached to the malleoli must be severed by short cuts, and close to the bone.

The astragalus is sawn off close to the cartilaginous portion by passing the saw through the two incisions. In order to perform this part of the operation successfully, the operator must practise it first on the cadaver; the assistant must use great skill in fixing the foot, and the wound is to be kept completely asunder with sharp hooks.

Hueter considers the removal of the astragalus with the straight narrow saw as the most difficult part of the operation, as the bone is almost invisible, while the saw is guided in the deeper portion of the foot almost exclusively by the point of the index-finger. Without this saw it would be necessary to separate the soft parts more extensively, in order better to expose the astragalus to view. Langenbeck, Hueter, and Volkman recommend, after arresting the hemorrhage and cleaning the wound, the introduction of a drainage tube. I have not done this in the case referred to above, as I did not consider it absolutely necessary in a partial resection. All surgeons unanimously recommend the plaster-of-Paris bandage, which enables the operator to keep the foot, which is now without any support, in the proper position at a right angle, so as to have the skin remain equally tense over the cavity.

A common bandage with windows is not suitable, as it is impossible to keep the wound clean and free from smell. The bandage designed by Volkman is

very good for this purpose. It consists of two capsules, one of which encloses the leg and extends a little above the moderately flexed knee, and terminates close to the upper margin of the wound, while the other capsule encloses the foot as far as the metatarsophalangeal articulations. These two capsules are united by a bridge made of sheet-iron and closely fitting the bend of the foot. In my case, which I have related above, this splint was modified somewhat. The upper end for about two inches was parallel to the leg, was continued into a bent bridge from the leg to the foot, thus assuming a half elliptical shape, and terminating in a piece two inches long and parallel to the dorsum of the foot. The splint or bridge had assumed this shape: Iron rings can be fastened to the

splint through which strings are passed for suspending the limb. The secretions are allowed to fall into a porcelain vessel placed underneath. On applying the bandage, the limb is protected from the splint by a layer of cotton. The wound is treated in the usual manner.

It is the purpose of the surgeon to obtain a solid, though immovable joint. Passive motions between the leg and the foot are better omitted, as a too movable, and, consequently, less useful joint would be the result. The function of an ankylosed joint is naturally not extensive, but sufficient for most purposes. Sir Astley Cooper has called attention to the fact that an ankylosed joint cannot be discovered in a person walking quietly, as the absent movability of the ankle-joint is supplied by the tarsal joints.

The gait of a person with an ankylosed tibio-tarsal articulation is defective, if the foot is not kept at a right angle with the leg, or is even in pronation or supination. Attention must therefore be paid during the after-treatment to the necessity of keeping the foot always in the right position, and not to allow it to deviate from the right angle. Langenbeck recommends the use of the mason's square, if the surgeon cannot trust his eye alone, in order to detect the slightest deviation. He quotes the following advice of Celsus, which covers the main principle of all treatment of diseases of the joints:

"Collocari quoque membrum quod ictum est, ratione certa debet; sic in inflammatione est, ut in neutram partem inclinatum sit."

THE REMAINS OF VOLTA, the Italian physicist, were disinterred on March 30th, at Camnago-Volta (Como), and, after being publicly exposed, were the next day placed in a marble sarcophagus in a mausoleum erected in his honor by his family. The opportunity was taken of obtaining measurements of the skull; the internal capacity of which, as ascertained by means of fine sand, was 1,865 cubic centimetres. According to the calculations of Professor Limbroso, this was larger than the skulls of Cuvier (1,829 cubic centimetres), and of Byron (1,807), and a little smaller than that of Cromwell. It much exceeds the ordinary Italian skull, which is about 1,500 centimetres in capacity.

Progress of Medical Science.

SIGNIFICANCE OF DISTURBED ACTION AND FUNCTIONAL MURMURS OF THE HEART.—Dr. J. R. Leaming read an interesting paper lately before the N. Y. Academy of Medicine, having the above title. He commenced with a review of arguments adduced in a former paper of his, relating to the mechanism of the first sound of the heart. Dr. L. holds that the first sound of the heart is wholly due to vibrations of the chordæ tendinæ of the mitral valve, set in motion by the action of the blood-current. This he regards as the key to the explanation of an important share of the morbid sounds of the heart. These morbid sounds he divides into *valvular* or organic murmurs, and *intra-ventricular* murmurs, which are "more or less functional." The murmur of a valvular lesion is the "bellows" murmur of Laennec, and is a friction sound of blood gushing through a narrowed aperture. The intra-ventricular murmurs, are nearly always due to irregular vibrations in the chordæ tendinæ. Their tone may vary from a soft blowing murmur to harsh sawing, rasping, or filing sounds, and where the vibrations are rapid, the tone becomes distinctly musical. Vegetations or calcifications of the valves projecting into the current of blood may sometimes be thrown into musical vibration, but this is very exceptional, it is claimed, and musical murmurs are almost invariably intra-ventricular. The intra-ventricular murmurs are termed functional, because due to irregularities in the heart's rhythm and not to valvular changes. Yet they occur in organic disease as well as in the so-called functional cardiac affections. They are believed to constitute a large majority of the morbid sounds in structural diseases of the heart, where they arise in consequence of the irregular tension of the tendinous cords produced by changes of structure. Where the intra-ventricular murmurs are purely functional, they have their source in nervous derangements, and may be traced most commonly to a disordered stomach or to indigestion.

Considerable importance is attached to the acoustic properties of the chest, as affecting the character of the cardiac sounds. Illustrative cases are given where the occurrence of pneumonia or pleurisy has caused the sudden disappearance of cardiac murmurs previously heard, and which returned with the lapse of the inter-current disease. The reason of this is supposed to be that the pulmonary effusions interfere with the transmission of the finer heart sounds to the ear. The mechanism is illustrated by comparing the chest to a musical instrument—to a violin; if a watch be suspended within the instrument, and a stethoscope is applied to the wall outside, the sounds of the watch will be conveyed to the ear clearly and distinctly, but if we now fill the cavity of the violin with sand or water, and then listen, no sound will be heard.—*Reprint from the Transactions of the N. Y. Academy of Medicine.* 1875.

CAUSE AND PREVENTION OF TYPHOID FEVER IN SCHOOLS.—Towards the close of the last year a serious epidemic of typhoid fever broke out in a well-known boarding-school for young ladies, at Burlington, New Jersey. For the purpose of ascertaining the causes which led to the outbreak, the trustees of the institution engaged the services of Dr. J. L. Leconte, as sanitary expert, who now presents the results of his investigations in a communication to the *Philadelphia Medical Times* (May 29, 1875). An examination of the

premises of the school elicited the following facts: Two large cisterns were situated near the school, from which the water supply was obtained. In building the cisterns it was necessary to cut holes in them in laying the floors, in order to relieve the pressure from the spring water, the floors being below the level of the subterranean drainage. These holes were afterwards plugged, and the water supply was derived entirely from the river. A year later, for some reason, the plugs were removed. Some three years ago, privy vaults were built, one of which was incautiously placed within a dozen feet or so of one of the cisterns. Leconte infers that matters gradually oozing from the vault had little by little contaminated the surrounding soil, till they finally gained access to the cisterns through the holes from which the plugs had been removed, and so polluted the water. As evidence that the polluted cistern water was the sole cause of the epidemic, it is mentioned that as soon as, at the suggestion of the physicians of the school, water only was used which was drawn directly from the river, not another case of the disease occurred. Several other significant facts are mentioned also. For instance, it was learned that no cases of typhoid had occurred amongst the servants, and on inquiry it was ascertained that they had not been in the habit of drinking the cistern water excepting in tea and coffee, that is, *after it had been boiled*. Moreover, the majority of the girls who had been attacked had drunk water alone—were not tea and coffee drinkers.

In conclusion, the writer calls attention to the following recommendations, which, if adopted, it is thought, will afford the most effectual means of obviating similar epidemics in future: 1. Before the plans of the building are fully matured, let an expert in sanitary studies be employed to give directions to the architect in all that relates to ventilation, drainage, and water supply.

2. After the building is completed, no alterations should be made affecting these three essentials of a good hygienic condition, without the suggestion of a practised sanitarian.

3. There should be stated inspections, say twice a year, of each institution by some sanitarian of acknowledged merit, who, after close examination and the correction of any defect, would give a certificate to be published in the circular or announcement of the school.

4. On the outbreak of any zymotic disease in the institution, the advice of a sanitary expert should at once be obtained, in order that means may be taken for its restriction, suppression, and prevention.

REMOVAL OF A MYOMA OF THE BLADDER, WITH RECOVERY.—A lad, twelve years of age, was brought to the clinique of Prof. Billroth on June 3, 1874, suffering from what was supposed to be stone in the bladder. The symptoms had existed for some ten months, and the most prominent were pain in the region of the bladder and in the glans penis, especially after urinating, with very painful, frequent, and almost involuntary micturition. Repeated and careful examinations with the sound, aided by the finger in the rectum, satisfied the surgeons that they had to do with a tumor attached to the posterior and upper wall of the bladder, nearly in the median line, that it was of the size of a small fist, and of uncertain nature. The following operation was performed on the twelfth day after his admission. The lateral perineal section was first made, and the diagnosis confirmed by introducing the index-finger. The bladder was then again entered by the snrapubic operation, the insertions of the two recti muscles being divided to gain room. For fear

that the tumor might be connected with the peritonæum through the wall of the bladder, it was decided not to use the écraseur, but to remove the growth near its base, having previously ligated the pedicle. This was done, and a drainage-tube passed through the perineal wound. The patient made a remarkably good recovery, having no fever after the sixth day. On the nineteenth day the urine was passed entirely through the urethra, the drainage-tube having been removed on the fifth day. The tumor was a trifle over three inches long, and rather more than an inch and a half wide, and in gross appearances strongly suggested a fibroma. The microscope, however, showed that it was mainly composed of spindle cells, which were not to be distinguished from those of the organic muscular fibres, thus constituting an exceedingly rare form of tumor in this situation. Besides these smooth muscular fibres there were also found a very large number of cells of the most various forms and sizes. The tumor was found to be directly connected through its base with the muscular coat of the bladder. Dr. Gussenbauer, by whom the case is reported, concludes that it should be classified as a myoma. —*Archiv für klin. Chirurg.*, xviii., 2, 1875.

POLYPI OF THE RECTUM.—Dr. W. Bathurst Woodman concludes an interesting article on the above subject with the following summary of his views:

Polypi of the rectum in children are probably less rare than is generally imagined. They generally grow from the posterior wall of the rectum. They are easily recognized by digital examination. Such examination should be made whenever the symptoms suggest a polypus. These growths should always be removed. Removal by the ligature, some form of écraseur, twisting off with forceps, the galvanic or gas cautery are the most appropriate methods.

The polypus may be gelatinous, cystic, warty, fibro-cellular (desmoid), or cancerous, and probably sarcomatous; possibly other varieties of structure may occur.

Of all the varieties the desmoid (fibromata) are the most common.

The pedicle, at all events, and sometimes the tumors themselves, are very vascular; hence the knife, if used at all, requires great caution.

There is often a tendency to spontaneous cure, which should not, however, be trusted to much.

The children of arthritic parents, and those suffering from the syphilitic, tuberculous, and cancerous cachexia, are most liable to these affections.—*The Medical Press and Circular*, May 5, 1875.

PRECAUTION AGAINST PUERPERAL INFECTION.—At a meeting of the German Medical Society, in St. Petersburg, Dr. Grünewaldt detailed the measures which were adopted at the lying-in asylum of that city to prevent infection. Acting on the theory that some wound or laceration of the parts concerned in labor presented a nidus for the reception of the disease, attention was also directed towards these points, and the results had been happy. The most common starting-point was held to be the vagina, or the mouth of the womb; at these points the poison was absorbed and the disease travelled onwards along the planes of connective tissue. The rule observed was to examine every woman, by the aid of a speculum, immediately after labor. Every laceration or abrasion was then carefully attended to, and as soon as a morbid appearance, such as diphtheritic deposit or the like, was noticed, a solution of carbolic acid in water, one part to twelve, was applied, or the sesquichloride of iron in a similar proportion. If the disease advanced, and there were signs of endometritis, injections were practised by

means of the double catheter. The indications for intra-uterine injections were:—1. Retention of the membranes. 2. Retention and decomposition of coagulated blood. 3. In lochiometra. 4. In any form of endometritis. 5. In secondary hemorrhage.—In fact, he said it was customary to use a weak solution of carbolic acid, one part to 400, as an intra-uterine injection, immediately after labor, in all cases, by way of prophylaxis.—*Rundschau*, April 12, 1875.

TO DISINFECT AND DEODORIZE EXCREMENTS.—Dr. Camerers, of Ulm, has tried some experiments with reference to this subject, using for the purpose diluted urine, and as disinfectants, carbolic acid, sulphate of iron, English sulphuric acid, and caustic lime. He has found that the sulphate of iron and the caustic lime alone are capable of preventing the formation of low organisms. He therefore recommends these latter for purposes of disinfection, as the most certain, the cheapest, the most free from danger, and as preserving their properties best when dissolved in water. Two classes of substances act as deodorants of excrements; first, such as fine sand, powdered mould, or clay, etc., which form a coating over the stinking surface; and second, such substances as charcoal, which absorb the offensive gases. He states that a vault with a capacity of 20 cwt. can be rendered perfectly free from smell in the course of twenty-four hours, by scattering about in it a few pounds of pulverized charcoal. The charcoal does not, however, prevent putridity and the formation of low organisms.—*Rundschau*, April 12, 1875.

POISONOUS DYES.—It is well known that the beautiful aniline colors are obtained by the aid of arsenic; the excess, however, Dr. Nowak states, may be removed from the finished material when the process is carefully conducted. When such precautions are not observed, and the coloring matters are used for confectionary and the like, disastrous results may follow. There has been less reason for anxiety about textile fabrics dyed with aniline colors, because of the very small quantity required to color silk and woollen materials, the arsenic being thus very much diffused, and the goods, moreover, losing any excess in the subsequent processes of washing, etc., by which they are prepared for market. This is not always the case, however, and the explanation of the occasional presence of dangerous quantities of arsenic is the following: Woollen and silk readily take the dye from the aniline solutions, but vegetable substances, such as cotton and linen, require previous preparation to enable them to do so. For this purpose a mordant is used, in this way: They are dipped into a solution containing clay and arsenious acid, which makes them capable of retaining the aniline colors, though at the same time it makes them highly poisonous.—*Rundschau*, April 12, 1875.

TREATMENT OF CHOREA BY ARSENIC IN LARGE DOSES.—Dr. Eustace Smith, in a note to the *British Medical Journal*, of May 1st, 1875, emphasizes the value of arsenic in chorea, but states that it was not so generally known that the curative value of the drug is greatly increased by administering it in full doses. Children have a remarkable tolerance for it, especially in such a non-febrile affection where there is no increased irritability of the digestive organs. To a child between the ages of five and six and twelve, he would give in this complaint as much as ten minims of Fowler's solution three times a day, directly after meals. The influence of the treatment is seen almost immediately, and it is rare for any of the physiological effects of the drug to be seen. Under this treatment, he says that severe cases seldom last longer than a fortnight.—*British Med. Journal*, May 1, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 3, 1875.

THE PREVENTION OF THE CONTAGIOUS DISEASES OF CHILDHOOD.

From the time that the various contagious diseases have been known as such, the great problem with the profession and with the laity has been how to prevent their spread. In ancient times the afflicted ones were banished, and left to die in some isolated place, for fear of spreading the malady. In fact, all sorts of barbarous regulations were enforced, which, from the present standpoint of an enlightened humanity, seems hardly credible. Since that time we have made many advances, and many points of dispute have been satisfactorily settled. On the great question of quarantine and other general measures to prevent the spread of epidemics there is a general agreement on the means to the end, which is dictated by a liberal conservatism, and by a desire to accomplish the greatest protection consistent with a proper respect for the liberties of the people.

This is all well enough so far as it goes, but very little, if anything, is done to prevent the spread of those diseases, contagious in character, which seldom if ever rise to the dignity of epidemics, or command a sufficient amount of interest with the general public to call for suitable legal enactments. Particularly is this the case with the contagious diseases of childhood. The number of children who are annually sacrificed to these scourges by the carelessness and ignorance of parents and guardians is simply appalling. While we admit that it is sometimes impossible to guard against the contagion of scarlet fever, measles, whooping-cough, diphtheria, and other like diseases, owing to the intricate and ramifying associations of society, we nevertheless have means within our control which, if judiciously used, may be the means of saving many precious lives. We have often thought that physicians do not take as much pains as they might in instructing the people concerning the direct contagious properties of these diseases, the great necessity for

thorough disinfection of the sick chamber, the importance of house quarantine, and the liability of carrying the poison by the clothes of attendants. We believe if the danger of transmitting the disease was fairly impressed upon the heads of families, greater care would be exercised in preventing the promiscuous intercourse of families, and would tend to discourage the abominable and useless practice of visiting the sick for the mere gratification of curiosity, and afterwards scattering the seeds of the disease through every household in the neighborhood. A writer in a recent number of *Harper's Bazar*, in speaking of the dissemination of contagion by means of ordinary visiting, makes the following statement, which doubtless has a parallel in the experience of almost every physician in general family practice:

"We have seen fine ladies making calls in a house where two or three children were down with scarlet fever, quite careless as to whether their next call was to be made in one where the children had not yet received the dark guest, and have met with the servants of a house as yet safe, chatting cosily in the kitchen with the servants of the house where the nursery was a hospital of contagion, and this when that especial disease is the most dreadful in all the known category of diseases, both at its height and in its results, and when the germs of its contagion live for weeks, and are so subtle and powerful that they have even been carried hundreds of miles in a letter."

We believe the only way to counteract this tendency to propagate the disease, is for each physician in attendance upon cases of the sort to establish a family quarantine, so to speak, and strive, by every reasonable means, to limit it to that quarter. If physicians also would be careful that they are not themselves the media for the spread of the disease, it would be well. We do not see why they should not be as particular in their intercourse with children, after seeing cases of scarlet fever, as they are bound to be with lying-in women while in attendance upon cases of erysipelas, pyæmia, and the like.

Another means of propagating these diseases is the school-room. In fact these places are considered to be the very hot-beds for the poisonous germs. But this is a matter to which we have so often referred in advocating the sanitary supervision of our schools, that it is unnecessary to give it more than a passing allusion at this time.

The attendance on the funerals of persons who have died of these diseases, is another of the many means of spreading the contagion. In cases of small-pox, this is prevented by the Health Board; but we are not aware that any attempt is made to hinder the promiscuous assembling of persons to attend the funeral of children dead with scarlet fever, measles, or diphtheria. Very frequently a great many persons attend who have no knowledge whatever of the disease which caused the death. Numerous instances of this sort have come to our personal knowledge, and have suggested to us the

practicability of publishing the cause of death with a notice of the funeral. This, it strikes us, could be enforced by the Health Board, and would, in a measure, at least tend to correct a great evil.

As we have before remarked, there are many circumstances connected with the spread of these diseases over which we may have no special control, but the proper education of the public concerning the contagious character of the disease, the establishment of house quarantine, of thorough disinfection, the exercise of care on the part of ourselves in carrying the disease from house to house, are besides other matters entirely within our control. If we conscientiously discharge our duties in this respect we will accomplish a great deal of good. At the present time, when so many families are changing their residences, when so many infected apartments are left to be occupied by unsuspecting victims, the matter assumes a very grave importance, and more than ever commands the attention of the family physician. The Health Board has it in its power to do the community a grand service by the inspection of all those houses having these contagious diseases. This is done in the case of small-pox, and we see no reason why it should not be the case with scarlet fever and other children's diseases. If this were so the houses could be properly infected and be kept sufficiently long in quarantine to render it safe for occupation. The same regulation might be enforced in regard to public hacks, which are notoriously liable to propagate all sorts of diseases. In these cases the licenses could be revoked until the vehicle was properly disinfected.

NECESSITY FOR INCREASED ATTENTION TO VACCINATION.

THE Board of Health have issued a circular, which has been sent to physicians in the county, calling attention to the increase of small-pox, and indicating the localities where it is most prevalent. A map is kept at the office of the Board of Health on which is indicated the location of cases as they occur, and physicians and others interested are invited to call and familiarize themselves with the relative distribution of the disease.

Since there is a certain proportion of people who decline being vaccinated when they are visited by the Inspectors for that purpose, saying that they prefer to have the operation performed by their own physician, the Board propose ascertaining the address of the physician in such instances, and will notify him of this fact.

Physicians are urged to pay special attention to vaccination, and revaccination is imperatively needed at the present moment.

The Board is using every means in its power to limit the spread of the disease, and deserves, as we hope it will receive, the hearty co-operation of the profession.

INDEPENDENT EXAMINING BOARDS.

THE editor of the *Philadelphia Medical Times*, in an article upon the reason why medical colleges are not endowed, speaks very truly as follows: "A number of medical gentlemen get together, apply to the Legislature for the right of giving a medical degree, and then produce an annual crop of doctors. Such is the brief history of the rise of a medical school. There are two distinct functions performed by its professors,—educating in medicine, and giving the right to practise medicine. It is not the first of these that the average student cares for solely, or even chiefly; it is the second that he wants.

"If any man doubts this, let him ask himself how many students would any institution get which simply taught medicine and did not give a degree.

"It is plain that the medical institution holds a valuable franchise from the Legislature, and expects to make the degrees pay for the medical teaching. The faculty is therefore pretty much on the platform of a firm united together for the purpose of profit. In an institution like Bellevue Medical College, where the faculty is self-appointed, the parallel is exact. In the University or the Jefferson Medical College, the only difference is that the firm has for its supposed advantage given up the power of selecting its own members. Under these circumstances it would be absurd to expect philanthropists to give money to endow medical institutions: as well might they add to the capital of Wanamaker & Brown, P. T. Barnum & Co., or any other combination of men engaged in a laudable effort for gain.

"In order to bring the medical colleges into their proper sphere of being simply schools of learning, the various Legislatures ought to take away their power of giving the right to practise, by creating State Examining Boards. But the colleges have it in their own power to place themselves in a position to obtain endowments without any legislative aid. Let them reform medical education by lengthening their courses and raising their standards, and then say to the public, 'Medical teaching, properly carried out, can never be self-supporting; we appeal to you for endowments.' If this were done, and the enormous influence the profession wields in the aggregate brought to bear, American medical colleges would lead the van, and would not be a by-word and a scoff among the institutions of learning."

The plan of independent examining boards is one which we have frequently urged in these columns, and must in our opinion initiate the reform in all matters connected with the present system of medical education.

DR. TILT.—Two of Dr. Tilt's works—his *Handbook of Uterine Therapeutics*, and *Change of Life*—have been translated into Italian by Dr. Rey, of Rome, and the Italian Government have made him a Knight of the Crown of Italy.

Reports of Societies.

NEW HAMPSHIRE MEDICAL SOCIETY.

EIGHTY-FIFTH ANNUAL MEETING.

SPECIAL REPORT FOR THE MEDICAL RECORD.

This Society met at Concord on Tuesday, the 15th inst., at ten o'clock in the forenoon, its proceedings rendered interesting by the presence of nearly one hundred members, many of whom took part in the discussions that ensued. After the formal opening and the election of new members, the President, the venerable Dr. Nahum Wight, of Gilmanton, delivered the anniversary address.

ADDRESS OF THE PRESIDENT.

After urging a more thorough education on the part of medical students, he advocated the formation of more local societies throughout the State, and the proper instruction of the public by the profession. The latter, he believed, would prove one of the best means of combating the growth of quackery in all its various forms.

REMOVAL OF THE ARM AND SCAPULA.

PROF. A. B. CROSBY, of the Dartmouth and Bellevue Medical Colleges, read a very interesting paper upon the "Removal of the Arm, Shoulder, Scapula, and more or less of the Clavicle at one Operation." The doctor commenced by saying that the paper was a filial tribute to the memory of his father, the late Dixi Crosby, M.D., LL.D., for more than thirty years Professor of Surgery in Dartmouth College, and he asserted that he only paid a just debt long due when he claimed for his father the honor of being the first to perform this formidable operation either in Europe or America. He gave a graphic description of the operation, which was performed in 1835, and then read an analysis of all reported cases of this operation. It was noted as creditable to New Hampshire surgery that the first three operations of this kind were performed by native surgeons in the order mentioned, viz., by Dr. Crosby, Dr. Mussey, of Hanover, and Dr. Twitchell, of Keene.

REPORT ON GYNÆCOLOGY.

The Society at 2 o'clock P.M. took a recess, and upon reassembling listened to a very able report upon gynecology from Dr. Wilkins, of Manchester. This paper evidently struck the right key-note, so far as this Society is concerned, for the speaker was warmly applauded when he condemned in no measured terms the fearful abuse lavished upon that unfortunate little organ by uterine specialists. He does not believe in holding the uterus responsible for all the ills of womankind, and reprehends the indiscriminate use of escharotics, intra-uterine pessaries, sounds, etc.

PLASTIC SPLINTS.

DR. HERSEY, of Manchester, then read a very practical paper upon plastic splints, illustrated by the exhibition of models, patterns, drawings, etc. After reviewing the history of plastic splints, and the materials used in their construction, he gave a very decided preference to plaster-of-paris and pasteboard, both strengthened and reinforced with thin strips of iron or zinc. A brief report from the Standing Committee upon Necrology closed the afternoon session.

The evening meeting was called to order at eight o'clock, when Dr. Child, of Bath, read a paper upon the

ABSOLUTE NEGLECT OF SANITARY LAWS IN THE RURAL DISTRICTS.

He stated, what every country practitioner knows to be true, that throughout the older settlements of northern New England farm-houses were built only with reference to the highways, no matter whether this brought the dwelling in a swamp or upon the north side of a hill, and the cess-pools, sinks, and wells were and are constructed as near the house as possible, with a view to labor-saving only. He instanced many such farm-houses in his vicinity, where the drainage from the stable and privies was allowed to filter into the family well, while the sink-washings were poured upon the surface with the vegetable débris of scores of dinners. What wonder, then, that typhoid fever, diphtheria, and scarlatina should prevail, even in the much-vaunted country air? The doctor insisted that the profession owed a duty to the public in teaching the fundamental rules of sanitary science and instructing their patrons how to avoid disease and promote longevity. He gave some simple rules for the arrangement of country dwellings with reference to drainage and water supply, and wound up with an appeal to the profession to do its full duty in the premises.

EPIDEMIC CEREBRO-SPINAL MENINGITIS.

DR. FOWLER, of Bristol, read a very interesting but brief paper upon epidemic cerebro-spinal meningitis. Following this there was a free and full discussion of the origin of typhoid fever and diphtheria, in which some twenty gentlemen participated. The treatment of the latter disease was discussed, and the use of pure quinine and chlorate of potass. fully endorsed, while all local treatment, except ice, was condemned. Dr. Jewett, of South Berwick, Me., a delegate from the Maine Society, gave in his adhesion to the views of Sir William Jenner concerning membranous croup and diphtheria.

The closing session of the Society was held at eight o'clock A.M., June 16, when some routine business was transacted, and a committee was appointed to obtain the passage of a law similar to the New York statute concerning the registry of physicians and for the suppression of quackery. It was voted to hold the semi-annual meeting, which is mainly festive in its character, at the Fabyan House, White Mountains, about the middle of September. Your reporter would add that upon this occasion, every September, the doctors of New Hampshire take their wives and daughters and make the meeting an excuse for a pleasure excursion of three or four days. In this they are joined by a great number of medical gentlemen from Massachusetts and Maine, and we should only be too happy to have New York City and State send us a full delegation, accompanied by their families.

The election of officers resulted in the choice of Dr. S. M. Whipple, of New London, as President; Prof. A. B. Crosby, Vice-President; Dr. G. P. Conn, Concord, Secretary; and Dr. Thomas Wheat, Manchester, Treasurer.

A STRIKE OF THE DOCTORS.—According to the *Journal de Genève*, the Canton of Glarus is threatened with a strike of doctors. Out of twenty-three licensed medical practitioners, twenty-one declare that they will no longer perform any official duties until the medical examinations be once more entrusted to a committee of competent men, and the regulations be so modified as to allow of the use of an effective sanitary police.

MEDICAL SOCIETY OF COUNTY OF KINGS
(N. Y.)

Stated Meeting, May 18th, 1875.

APOCYNUM CANNABINUM—ITS VALUE IN DROPSICAL
AFFECTIONS.

DR. HUTCHINS, in a case of general anasarca, complicated with pleuritic effusion and hydropericardium, where the patient, a man of sixty, was suffering from extreme dyspnoea, the result of the enormous distention, after the failure of all the expedients used to excite the kidneys, made a trial of the apocynum cannabinum, based on the somewhat remarkable experience of Dr. Jewett, of Canandaigua, N. Y. (The reader is referred to an article contributed by this gentleman to the N. Y. State Med. Soc., and published in its *Transactions* for 1869, pp. 137 to 139.)

The drug was procured from a well-known house and prepared *pro forma*, and was administered without effect. Specimens were obtained from other drug houses, and several fluid extracts were used, and still without effect. Believing that Dr. Jewett's experience was not mythical, he was appealed to for advice, and some of the drug, of his own collecting, was forwarded by mail, prepared according to directions, and administered to his patient. In 48 hours the man, who had been so frightfully distended, was reduced to a skeleton. Though he died about a year afterwards, the water never again accumulated, any disposition thereto being immediately relieved by the infusion of this drug.

With additional supplies, obtained from Dr. Jewett, Dr. Hutchins had promptly relieved two cases of dropsy following scarlatina, and one case of phlegmasia alba dolens.

Dr. Jewett, under date of February 16, 1875, writes: "The woody fibre of the root has little value. You will find the bark intensely bitter, and that it has to be used with some caution, or it will provoke vomiting and diarrhoea.

"Its great value consists in its diuretic action, which will be impaired by any hydragogue cathartic. Sometimes its effects are direct and positive, at others, and especially in case of vicarious action of bowels, it is more tardy.

"I have the report of a case from Buffalo of hydrothorax, with general dropsy, where the amount of urine in the first 24 hours was incredible, after all the ordinary remedies had been exhausted, and the man 'given up.' The milk weed was given empirically by the nurse, and the patient is fast recovering.

"If your patient will bear stimulants, I would give the medicine in gin, and combine with it an ounce or two of juniper berries, breaking the skin of the berry, but not the seed.

"Put half ounce in a pint of gin, add an infusion of two ounces of juniper berries in a pint of water. If the stomach and bowels are irritable, give a teaspoonful every four hours. Give 2, 3, or 4 teaspoonfuls at a time, if the stomach will tolerate it, until the effect is obtained.

"An experience of thirty years in its use has given me unbounded confidence, if properly used. I could astonish you with the cases that have come under my observation since the publication of the article in the *Transactions*."

Under date of June 14th, 1875, Dr. Jewett writes: "A case came to my notice yesterday where a medical man, who was skeptical as to its efficacy, was induced to try it at my request, as every other remedy had been

exhausted. The preliminary arrangements were made for the funeral. The patient took the *milk weed* and is well to-day."

Dr. Hutchins argued that Dr. Jewett's experience with the apocynum cannabinum of his own collecting, and the prompt action of the drug furnished by Dr. J. in the cases above related, combined with the fact of the utter failure to procure any appreciable diuretic effect from the various specimens or fluid extracts, as kept by prominent drug houses, lead to the conclusion that the apocynum, capable of producing diuresis, is not usually, at least, to be obtained in the shops.

The Dispensary asserts that the *root* is the official part. Dr. J. claims, and the facts support the claim, that the *bark of the root* is alone active.

Four specimens were shown to the Society, one from Dr. Jewett, which was the *bark of the root*, and three others, obtained from three leading drug houses in New York, one being the *woody fibre* without the bark, one being the *whole root*, and one being the *leaves and stems*.

Dr. H. was cognizant of a case of an elderly gentleman, subject to occasional attacks of dyspnoea from hydropericardium, which were speedily relieved by a very minute dose of the fluid extract frequently repeated.

Dr. ARMOR expressed his great interest in the case reported by Dr. Hutchins, for he had similar experience in the use of the *apocynum*. In a case of general anasarca under his observation, a few years since, at the suggestion of a consultant physician, he was induced to try this, to him, at that time, a new remedy. The dropsical accumulation was immense, and all the usual remedies had been tried in vain. The apocynum was administered in the mode suggested by Dr. Hutchins, and within seventy-two hours the patient was drained almost to the condition of a skeleton! The effects were the most marvellous that he had ever witnessed. The patient was somewhat exhausted, but readily rallied under the use of general tonics and stimulants. He was kept on the use of quinine and tincture of iron for months afterwards, during which time there was little or no return of the dropsy.

Encouraged by the prompt and powerful action of the new remedy, he determined to give it further trial in the wards of the Long Island College Hospital, but his experience there somewhat disappointed his hopes. In one case of general anasarca the effects of the remedy were almost as prompt and powerful as in the case just cited—the fluid rapidly disappeared, and the patient, under general supporting and tonic treatment, made a good recovery. In other cases, however, apparently similar in every respect to the ones reported, the remedy—although the same preparation of it was used—had little or no effect. Now, what is it which, in one case, gives us such prompt and powerful action of the remedy, and in another we get no therapeutic effects whatever? I studied the action of the remedy in the cases observed with great interest, but am not able to answer the question suggested. The cases were apparently similar, and the remedy and mode of administration were the same. It is proper, however, that I should state that in the cases in which I failed to remove the fluid by the *apocynum*, I subsequently tried the usual remedies, such as digitalis, squills, calomel, iodide of potash, etc., with similar results. On the whole, I am favorably impressed with the remedy, and shall give it further trial. I have little confidence, however, in cathartics, diuretics, apocynum, or any other medicinal substance, in removing fluid effusion in closed cavities when it results from acute or sub-

acute inflammation of serous tissues. The fibrinous deposit, interposed between the subpleural vessels and the liquid effusion, greatly impedes the absorption of the serous fluid; beyond a certain point I very much doubt the value of pushing hydragogue cathartics and diuretics. A very marked distinction should, I think, be made between an effusion in a closed cavity, the result of an *exudation*, and that which results from a *transudation*. In the one instance it is an *inflammatory* product, and requires time or surgical interference for its removal; in the other it is a mere *transudation*, the result of a general dropsy, and is readily removed by appropriate medication. It is only in the latter form of effusions into closed serous sacs that I would have confidence in apocynum, or watery cathartics, or diuretics; in other words, the value of these agents is in proportion to the general character of the dropsy.

Dr. BURGE referred to cases lately treated by him with the fluid extract of apocynum cannabinum.

1st. A lady, three weeks after confinement, consulted him on account of ascites and general anasarca. Urine highly albuminous. Ten drops of the fluid extract every three hours caused profuse and persistent diuresis. The anasarca was promptly and permanently relieved. At the end of three weeks the peritoneal cavity was emptied by means of the aspirator. The patient continued the remedy in five-drop doses three times a day, and at the end of one month the disposition to effusion seems to be overcome.

CASE 2.—Called to see a child at 6 months. Found him with hot dry skin, staring expression of countenance, fontanelle prominent and with a feeling of fluctuation. The mother said he was extremely restless, and she thought his urine scanty. Half a drop of the fluid extract of apocynum cannabinum was given every three hours, in some pleasant vehicle. After several doses, he vomited once. The medicine was then given three times a day, and after the second day the fontanelle was perfectly natural, and the child seemed as well as ever. At the end of three weeks he had a similar attack, which was treated in the same manner and with the same result. He is now well.

Dr. Burge took exception to the view which was strongly expressed by prominent members of the Society, viz., that medicines have no power to reduce an accumulation of serum in the pleural and peritoneal cavities. These effusions often subside spontaneously, and why may they not be hastened by appropriate medication?

In cases of acute pleurisy and rapid effusion, the fluid is often as rapidly absorbed, and Dr. B. had always ascribed some efficacy to the means which he had employed.

SINGULAR OBSTETRIC CUSTOM.—A correspondent of the *Lancet*, speaking of an absurd custom which prevails in Yorkshire, says: "The patient is confined with her clothes on, *all* her clothes (except perhaps her bonnet and shawl)—boots, stockings, drawers, petticoats, stays, dress, and the rest. If labor happens to set in when the woman is undressed in bed, the first rush on the part of herself and friends is to get her clothes on. She then usually lies down on the under mattress, the upper mattress or bed being turned over out of the way, and the labor goes on to its termination." When the placenta comes away the woman, without any further delay, is "got into bed," as it is called. The process consists in her getting up and standing on the floor, or sitting in a chair, while her clothes are taken off, a clean night-dress put on, and the bed made, when she mounts into it as if nothing in particular had occurred."

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting, June 4th, 1875.

Dr. E. R. PEASLEE, PRESIDENT, in the Chair.

Dr. R. TAUSZKY read a paper upon the "Uses of Water in Fevers, according to the Views of Dr. Winternitz, of Vienna," of which the following is a brief abstract.

The mortality from fevers has lessened considerably since the application of water in their treatment has been practised by skilful hands.

Febrile diseases become more dangerous to life the greater the production of heat within, and the less active the removal of the heat from the body.

It is the principal duty of the physician in the management of fevers to lessen the fever heat by all the means at his command. If our interference with disease is not precise, we can never expect measurable results.

We must know how to do, if we wish to do right, and a strict method is necessary in physical therapeutics. We are at present far from possessing precise methods, but the little we do have of precision is of great value.

The following, according to Winternitz, are the methods in which water is to be used.

Simple abluion, friction-baths, half-baths, full-baths, shower-baths, wet pack, continuous local, and continuous general baths.

The indication for simple abluion, or the sponge-bath, is where the temperature is not over 101° or 102° F. When used in higher fever it is principally for its effect as a nervous stimulant; it also prepares the skin for more potent measures. This means must be repeated every half hour, accomplishes the desired result only in a very unsatisfactory manner, and will produce elevation rather than lowering of temperature if not followed by a more potent measure.

The friction-bath is more useful than the simple abluion, and is accomplished by wrapping the patient in a sheet wet in water at a temperature of 62° to 53° F. Before applying it, cool the head for the purpose of preventing congestion of the brain, which would otherwise follow. This bath has the advantage of being purely a nervous stimulant. It causes dilatation of the blood-vessels of the periphery of the body, and must have, as a matter of course, a great influence upon the action of the heart. Rubbing the skin gently also increases the amount of evaporation more than fifty per cent.

In children, especially in the eruptive fevers, when this bath is used the exanthema will appear in full view, thus rendering diagnosis certain in many cases where it was before uncertain. It is especially serviceable also in acute articular rheumatism, first wrapping up the inflamed parts and rubbing the cooler parts of the body until these get warm. The half-bath must be continued from twenty to thirty minutes, and the temperature should not be lower than from 65° to 54° F. It may be assisted by pouring water over the neck, chest, and back. If the patient is very sensitive, it is well also to first place a cloth over the head and pour water upon that, particularly if dealing with patients who are unconscious. The half-bath is preferable to the full-bath. In the full-bath the weight of the water prevents proper reaction. The disadvantages of too cold a bath are that the colder the water used the quicker the reaction, and the sooner the return of the fever heat; and it is also too powerful a nerve stimulant, and will sooner exhaust a patient. A patient

should never feel chilly while in a bath, and as soon as the skin begins to assume a bluish color he should be at once removed.

The patient is more likely to feel chilly in the full-bath than when the half-bath is used. It may be set down as a rule, that the water used for lowering the temperature when fever is present must be of a lower degree than for cooling the healthy body. Elevation of temperature will soon take place when the wet pack is used, but there is no means of reducing the pulse as quickly as it can be done by this method. The principal rule to be observed in the use of water is to methodically repeat whatever method of application is used, and neither during the day nor during the night to permit the continuance of a high temperature for much length of time.

Correspondence.

THE PRESBYTERIAN HOSPITAL AFFAIR.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: It seems to me that even your admirable editorials and the correspondence they have called forth, still leave something to be said on the "Presbyterian Hospital Affair." May I venture to add, then, *first*, as to the matter of advertising which has been charged upon some of the signers of the protest by "*Medicus*," with the approval of THE RECORD? It is hard to be serious in the face of the charge that sixty-odd of the hospital appointees of New York have, by allowing the publication of their names and titles in *The Tribune*, appended to a protest in a matter between laymen and physicians, violated the law which states that we shall not advertise that we practise "special branches, as extra inducements to patronage," or that they have thus resorted to "public advertisements." If this kind of interpretation of the Code goes on, the fact of the appointment of medical men to hospitals by laymen will soon be kept sedulously from reporters, and be only known to the Managers. The second quotation from the Code refers obviously to differences between medical men. The Code, indeed, as quoted by your correspondent, states this explicitly; *e.g.*, "The feelings of medical men may be painfully assailed in their intercourse with *each other*." With all due deference to "*Medicus*," it is the opinion of the present writer that the Code not only does not answer his question, but has nothing to do with it. This hospital affair is a difference between cultivated and distinguished laymen on the one hand, and the majority, as I believe, of the thoughtful members of the profession in New York on the other. The fact that a minority of the medical officers of the hospital persist in adhering to the Board of Managers in their action, which, it is believed by the profession, brings dishonor upon it, only goes to prove what has been urged in THE RECORD, that medical men have "invited the issue" by playing "the part of toadies to the appointing power." This affair being then a contest between a professional and non-professional body, as one of the signers of the protest I am glad that it was published in *The Tribune* as well as THE RECORD, and I fail to find any violation of our Code in it.

Secondly, as to the actual matter at issue, all of the professions will be greatly interested in the justification of the Managers, or the majority of them; the minority need no justification, which is promised us by "*Medicus*." It is hard for those who are not of the Managers of the Presbyterian Hospital, and for some who are, to see why it was well to "fail to re-elect four compe-

tent medical men," without giving them a chance to be heard, even if the Visiting Committee said "it was all right," and even if they were advised by other Boards, that when they had any trouble between doctors and superintendents, to "get rid of the doctors." It is harder still to conceive how reputable medical men could assist in any such procedure. Without explanation, it remains a stigma on our calling, which we are in all self-respect bound to cast off and repudiate. The merits or demerits of the gentlemen who failed of a re-election have nothing to do with the question, which simply is, Why were they condemned unheard? To this point we hope "*Medicus*" will turn his attention in his championship of a Board of Managers who will not answer for themselves.

As to your correspondent "*Veritas*," his argument seems to be, that because, as he claims, such things as this Presbyterian Hospital affair have, with the connivance of medical men, been done before, in the Nursery and Child's Hospital and Bellevue, therefore the profession should be quiet now. Assuming these cases to be parallel with the one now under discussion, we may simply answer that three wrongs will not make one right, and instead of objecting to the present protest, let us rather rejoice in the advance of medical unity and *esprit de corps*, in the aroused sense of fair play in the profession, which, if kept up, will finally put a stop to both the encroachments of laymen and to the artful connivances of medical men, if such are practised, who attempt to manage hospitals and dispensaries in their own selfish interests, by cringing to boards of direction, that "thrift may follow fawning."

The issue as to our rightful status in hospitals, it seems to many of us, may as well be met now as to be postponed. Let us as a united profession submit to nothing which makes us less than the peers of our fellow-philanthropists. We must as a profession be adequately represented on Boards of direction. Then if rebukes are needed, medical officers will receive them from a source fully competent to judge of their delinquencies. Boards of Managers of large numbers, with only one or two of the medical staff upon them, will never be free from the suspicion of being controlled as to medical matters by one or two men. The system that admits all but the assistants in the medical department to seats among the directors already obtains in some small hospitals in this city and Brooklyn. Wherever it does, no such proceedings as those which have greatly impaired the noble charity of a noble man, have ever occurred, will ever occur. It is within my personal knowledge that the advice has already been given to one of the Managers of the Presbyterian Hospital, by one of another similar institution, "never to yield to doctors." I will not say that we should never yield to laymen in matters of which they know better than the medical profession, much less that we should condemn them unheard; but conceiving as I do that in this matter the honor and dignity of our calling are involved, much as we all must regret any collision with such eminent and philanthropic gentlemen as form the Board of Managers of the Presbyterian Hospital, or with those medical men who retain or accept positions in its medical staff, I do not see how we can do less than protest, and also solemnly refuse to give our professional countenance to proceedings, which, in the lack of better information than is now before us, must be stigmatized as unjust, and as tending to degrade the members of our profession.

With great respect,

D. B. ST. JOHN ROOSA.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from June 20th to June 26th, 1875.

SIMONS, JAMES, Surgeon.—Relieved from duty in Department of the Gulf, and assigned to duty as Attending Surgeon and Examiner of Recruits in Baltimore, Md. S. O. 121, A. G. O., June 19, 1875.

HEAD, J. F., Surgeon.—Granted leave of absence for one month. S. O. 85, Department of the South, June 23, 1875.

McCLELLAN, ELY, Assistant Surgeon.—Having reported in compliance with S. O. 121, e. s., A. G. O., assigned to duty in the office of the Medical Director of the Department. S. O. 85, Department of the South, June 23, 1875.

JANEWAY, J. H., Assistant Surgeon.—Relieved from duty in Department of the Missouri, to proceed to New York City, and upon arrival report by letter to the Surgeon-General. S. O. 121, e. s., A. G. O.

KOERPER, E. A., Assistant Surgeon.—Relieved from duty as Attending Surgeon at Detroit, and assigned to temporary duty at Fort Wayne, Mich. S. O. 124, Military Division of the Atlantic, June 19, 1875.

DE LOFFRE, A. A., Assistant Surgeon.—Granted leave of absence for one month on surgeon's certificate of disability. S. O. 106, Department of the Missouri, June 21, 1875.

Medical Items and News.

THE SUCCESSOR OF LIEBIG in the professorship of chemistry in the University at Munich is to be Prof. Baejer, of Strasburg.

MEASLES IN THE FIJI ISLANDS.—*The Lancet* says, in referring to the epidemic of measles, which is said to be almost depopulating these islands: "Hundreds have already died, and for the last few weeks eight or ten deaths have occurred every day. A fatal termination of the malady is ushered in by dysentery. Although the families of white residents have been attacked, no fatal seizure has yet been reported among them. The natives are too frightened and suspicious to submit themselves to medical treatment, hence they are terribly punished. Precautionary measures towards suppressing the disease have been ordered by the government, but the general panic renders it impossible to enforce them. By the latest accounts trade was quite at a stand-still, and the number of deaths reported to have already occurred is said to be 50,000, although this is undoubtedly a gross exaggeration."

SCARLATINA is epidemic in Chester and Montgomery Counties, Pa., and is reported to be malignant in type, and attended with great mortality.

DRS. ISAAC E. TAYLOR AND GOUVERNEUR M. SMITH have resigned their positions as Visiting Physicians to Bellevue Hospital, and the former has been appointed Consulting Physician. Professor Alpheus B. Crosby has been appointed Visiting Physician in the place of Dr. Taylor, and Dr. J. P. P. White to the Department of Children in place of the latter. Dr. White has resigned his position as Visiting Surgeon in Charity Hospital.

THE MEDICAL DEPARTMENT of Yale College is to celebrate its anniversary on the 28th ult.

PHARMACY IN JAPAN.—With the view of obviating adulteration, laboratories have been established by the Japanese Government at Jedo, Kiyoto, and Osaka, for the purpose of examining drugs, and of giving Japanese youth practical instruction in pharmacy after having passed through a theoretical course in natural science. Dr. Dwars, formerly of Amsterdam, is at the head of the laboratory at Osaka; and Dr. Geerts occupies a similar post at Kiyoto. The Japanese Government have ordered, that any druggist who has in his possession sulphate of quinine or iodide of potassium in the adulterated state shall be punished for the first offence by a fine of fifty yan (\$25).

SOUTH AMERICAN SKULLS.—The Emperor of Brazil has recently sent to Professor Virchow, of Berlin, a very interesting collection of skeletons and skulls (including some found in old caverns in Brazil), together with an autograph letter.

RIDES FOR CONVALESCENTS.—During the warm season, for two years past, the board of government of the Boston Young Men's Christian Union have furnished carriage rides for many of the patients in the hospitals of their city, giving them the benefit of short excursions into the fresh air of the country. They are now, for the third season, soliciting funds for the continuance of this excellent charity.

PUNISHMENT OF ABORTIONISTS.—On May 24th, Dr. Smith and a Mrs. Ingham, convicted of causing an abortion, were sentenced, in Quincy, Ill., to eight years' imprisonment each.

A DR. ZEILLS, of California, has sued the famous James Lick for professional services, amounting to \$55,000, to which Mr. Lick claims a full offset in his bill against the doctor for board and lodging.

SAMUEL POLLOCK, M.D., read the poem at the commencement of Dickinson College, at Carlisle, Pa., on the 22d ult.

THE PUBLIC BATHS which the city has for three years past provided for the public were again opened on the 10th ult. This year they are located at the foot of Fifth Street on the East River, and at Tenth Street on the North River. They are open daily, except Sundays, from 5 A.M. until 9 P.M. No person will be admitted without tickets, which are distributed free, but subject to refusal on the part of sanitary or police officers. These swimming-baths have become so popular that, it is reported, on the 12th ult. twenty-five thousand persons applied for permission to bathe.

PROFESSOR BUFALINI, of Florence, the author of a well-known essay on Life, and of an esteemed work on Analytical Pathology, died at Florence on March 30, in the eighty-eighth year of his age. His funeral ceremonies were performed on the most splendid scale, and were attended by representatives of all the learned societies of Italy and the Universities of Pisa, Rome, Palermo, Maurata, Pavia, Modena, Padua, and Turin. Amongst the pall-bearers were the Italian ministers of agriculture, commerce, and public instruction; the Mayor and the Prefect of Florence, the President of the Institute, and the President of the Medico-Chirurgical Association. By his will Professor Bufalini has left a prize of 10,000 francs, to be awarded every ten years, to the writer of the best essay on the true indications of the experimental method in all scientific researches and acquisitions, which shall also embody the applications attained by the divers sciences, and the progress which the experimental method has made, during the period which has elapsed between two competitions.

DR. C. L. PECK, of Burlington, Vt., sails in a few days for Europe, and our readers may expect to hear through him interesting intelligence on medical matters from various points.

A BAVARIAN PRINCE has adopted the profession of medicine, and is said to have become a very successful practitioner. Recently he performed a very difficult operation at the Munich Ophthalmic Hospital.

DR. W. K. BOWLING has resigned his connection with the Nashville *Journal of Medicine and Surgery*.

DR. M. GONZALEZ ECHEVERRIA, lately of this city, is soon to publish in London a new work on the medical and legal aspects of epilepsy.

FEMALE MEDICAL STUDENTS.—Twenty-four female students have pursued their studies during the winter session of the London school, recently established.

CURIOUS BELIEF IN "MATERNAL IMPRESSIONS."—A writer in the *Field*, an English sporting journal, on the subject of the "New Norwegian Game-Laws," says: "On my return to Trondhjem, (bringing game, including a hare), I met an acquaintance, who, seeing the hare, besought me with much earnestness to cut off its nose. I inquired his reason for wishing me to mutilate the animal thus. Replied he, 'I do so for your sake; you are rendering yourself liable to a fine. It is an article of belief here that, should a woman in an interesting condition see a hare that has not been deprived of its nose, her child will be born hare-lipped. The law protects the new-born.'"

VIVISECTION.—THE HOSPITAL AT FLORENCE.—A Philadelphia correspondent of the *Lancet* says: "A severe criticism has recently appeared in a Florentine newspaper upon the enormously multiplied vivisections of Professor Schiff, of that city. It is stated by the Italian editor that, within the past few years, 15,000 dogs have perished under his hands, and the editor very pertinently asks what adequate result has been achieved through all this hideous suffering? It appears, also, that Professor Schiff obtains his dogs through the agency of dog-stealers, who are paid by him. It may seem strange that the Florentine municipality should permit this without interference; but the fact will appear less surprising when it is known that this body is almost as indifferent to human suffering as to canine. The hospital at Florence has a most unenviable reputation. The mortality amongst its inmates is so great that, with the lower classes, to be sent to the hospital is considered to be pretty much the same thing as to be sent to one's grave. The stench is sometimes perceptible in passing along the street. It will scarcely be believed that the severest operations are performed in it without the use of anesthetics—at least this was the case two years ago, when I made a long stay in Florence, and received this fact on excellent medical authority. The reason assigned was that the chloroform furnished the hospital was so dangerously bad, that the surgeons were afraid to use it."

THE GERMAN SANITARY ASSOCIATION will be held this year in Munich, on September 13th, 14th, and 15th. The following questions have been proposed by the committee for discussion: 1. The determination of a plan for examining into the local and temporal causes of epidemics of typhus (including enteric fever): reporters, Professor von Pettenkofer and Dr. Port. 2. The sanitary requirements of new buildings, especially in new quarters of large towns: reporters, Dr. Varentrapp, Engineer Burkle-Ziegler. 3. The sanitary requirements as regards diet in orphan asylums, barracks, prisons, and alms-houses for old persons, and also in public kitchens: reporter, Dr. Voit. 4. On

the object, means, and limits of a sanitary police control over some important articles of food, especially bread and meat. 5. On public slaughter-houses and the introduction of a general supervision of the slaughtering business, and of a compulsory inspection of meat: reporters, Burgomaster Gobbin and Dr. P. Börner. A sixth subject for discussion is proposed by Dr. Lunt, of Cologne, viz.: the establishment of a general law for Germany, on the examination of dead bodies, with, as far as possible, a medical determination of the cause of death.

VIVISECTION IN ENGLAND.—The English Government proposes to appoint a Royal Commission to inquire into the facts relating to experiments on animals. In view of this action, the bills before the Parliament will probably be withdrawn if they have not already been, and the real facts of the case will be made public, freed from the sensational element which has its origin among those who with time and money on their hands, and sensitive emotional natures, undertake the reform of what appears to be an evil, without first taking the trouble to become familiar with the subject.

CHANGES IN THE MEDICAL FACULTY, MCGILL COLLEGE, MONTREAL.—Dr. Geo. W. Campbell, Dean of the Faculty, has resigned the chair of Surgery after an occupancy of 38 years. Dr. Geo. E. Fenwick succeeds Dr. Campbell as Prof. of Surgery. Dr. R. T. Godfrey (late of Bishops' College) has been appointed to the chair of Hygiene, and Dr. T. G. Roddick as Prof. of Clinical Surgery. Dr. W. Gardner (late of the Bishops' College) has accepted the chair of Medical Jurisprudence, and Dr. Sheppard has been appointed Demonstrator of Anatomy.

THE SANITARY ASSOCIATION OF MONTREAL.—A number of the prominent citizens of Montreal have formed themselves into an association with the above title, with a view to improving the sanitary condition of their city. There is already a health board in operation, and the design of this association is not to interfere with the legally constituted authority, but to second their efforts by arousing public and individual attention to the urgency of adopting sanitary measures.

WISCONSIN STATE MEDICAL SOCIETY.—At the twenty-ninth annual meeting, which was held at Madison, on the 2d and 3d ult., the following officers were elected for the ensuing year: *President*, J. B. Whiting, of Janesville; *Vice-Presidents*, Ira Manly, Jr., of Waukesha, and F. Semm, of Milwaukee; *Secretary and Treasurer*, J. T. Reeve, of Appleton; *Assist. Secretary*, Dr. Nichols, of Milwaukee. Milwaukee was designated as the next place of meeting, and the following gentlemen were elected delegates to the American Medical Association: Drs. Manly, Waterhouse, Strong, Palmer, Butterfield, Fox, Dodson, Mason, Armstrong, Rogers, Stansbury, Bond, Griffin, Cory, Zieley, Britt, Linde, Whiting, Smith, and Hobbins. The committee appointed to take measures to secure a law for the appointment of a State Board of Health, reported that, thus far, efforts had been unsuccessful. A resolution was adopted declaring it inexpedient that a medical college be established in Madison.

TESTIMONIAL TO SEÑOR GARCIA.—A number of English physicians have resolved to present Señor Garcia with a testimonial of their appreciation of his researches in relation to the physiology of the larynx and the mechanism of phonation, and have appointed Dr. Louis Elsberg, of this city, Honorary Secretary for the United States. Dr. Elsberg will receive such subscriptions as the friends of Señor Garcia in this country may like to make to the fund.

Original Communications.

A CASE OF INTESTINAL OBSTRUCTION —OPERATION AND REMARKS UPON THE OPERATION OF LAPAROTOMY.

By ERSKINE MASON, M.D.,

PROFESSOR OF CLINICAL SURGERY, ETC., UNIVERSITY MEDICAL COLLEGE, NEW YORK.

On the afternoon of May 1st, 1875. I was asked by Dr. Henry F. Walker to see with him a patient in his service at Bellevue Hospital who was suffering from obstruction of the bowels. The history of the case, as recorded by Dr. Hill, House Physician, was as follows:—Mary D., æt. thirty-four, widow, born in England, was admitted into Bellevue Hospital, April 26th, 1875. She had had two living children and several miscarriages, the latter caused, she believed, from ill usage at the hands of her husband. After the birth of her first child (nineteen years ago), she gave the history of suffering from a severe attack of peritonitis. From that time to the present she had enjoyed good health. On the night of the 21st of April (Wednesday), she retired, feeling well (her bowels had not, however, been moved for two days previous). During this night, she was seized with severe pain in the bowels, and the following day the pain became intense, and the abdomen began to swell. The swelling continued to increase, and on Saturday, the 24th, she was seen by a physician, who ordered her an injection of warm water and oil of turpentine: this afforded no relief, but the following day, she stated two or three hard pieces of feces were expelled. Accompanying these symptoms, there had been frequent vomitings. When she entered the hospital her bowels were quite tympanitic, and when examined, she complained of a general soreness over the abdomen rather than acute pain; she also vomited frequently a greenish fluid. In spite of the treatment she received while in the hospital, which consisted in the use of morphia, cathartics, and large enemata by means of the long rectal tube, her condition was not improved; and her symptoms became more urgent.

When I saw her, she was lying upon the back with her limbs extended, movement of the bowels, giving her no pain. There was no prolapsus of the bowel, nor had there been any bloody or slimy discharge from the rectum, nor the presence of any hernia. Her face was flushed; pulse weak, 104; R 24; T 99½. All her symptoms had been aggravated to-day. The secretion of urine had not diminished, and the vomiting, which was now almost constant, especially if anything was swallowed, had never become stercoraceous. No pain was complained of, and none elicited upon percussing the abdomen, which was extremely tympanitic, save over the right hypochondriac region corresponding to the hepatic flexure of the colon. A general consultation of the physicians and surgeons of the hospital was called, which met the following morning to take into consideration the propriety of surgical interference. On the morning of the consultation the patient's general condition was about as on the previous afternoon, her abdomen if anything was more tympanitic. The general opinion expressed was that the obstruction existed in the small intestines, and in all probability due to the presence of bands, the result of her old attack of peritonitis; and the only thing that offered any prospect of relief lay in abdominal section, or laparotomy. As regards myself, I was rather

inclined to the belief that we should find the difficulty to exist either in the transverse or descending colon, and my reasons for entertaining this view were as follows:—First, that the only locality in which pain was complained of, was over the transverse colon in the vicinity of the hepatic flexure; second, because we were informed that the long rectal tube had been supposed to have encountered obstruction in the vicinity of the sigmoid flexure; and third, because the secretion of urine remained free—it having been observed by the late Dr. Barlow, Mr. Hilton, and others, that where the small intestine is interfered with, this secretion is diminished or suppressed. It is true, however, that this is more manifest the nearer the lesion of the small intestine is to the pylorus.

The patient was accordingly removed to my service in the hospital for operation, which was done at half-past three on the afternoon of Sunday, May 2, the fourteenth day since the bowels had moved, and the twelfth since the attack of pain. At the time of operation, her condition could not have been worse, her extremities were cold, and she was suffering from extreme prostration. When under ether, I introduced, through the abdominal walls, into the transverse colon the fine canular of the aspirator: this allowed the free escape of gas and the abdominal walls became flaccid. An examination now revealed the presence of no tumor. Placing the patient upon her left side, I now passed my right hand up the rectum a distance of seven inches, measuring from the tip of my middle finger. The fingers could be swept over the promontory of the sacrum and around the true brim of the pelvis, but thus far no obstruction could be detected. This examination occupied some moments, and I was compelled to desist from farther attempts to examine the bowels farther up owing to the tightness with which my hand was grasped by the external sphincter, and from an impediment which was offered by the tip of the coccyx, which turned abruptly forward. This latter, in the case of my patient, presented a serious obstacle to manual examination of the bowel through the rectum, which I had not met with in a previous similar examination, nor have I observed it mentioned by others who have called attention to this mode of exploration. Had I prolonged my research in this direction, or used more force to overcome the obstacles that have just been mentioned, I fear I should have but added to the gravity of the case a ruptured bowel.

The patient being now placed upon her back, with the assistance of my colleague, Dr. Frank H. Hamilton, I proceeded to the operation of laparotomy.

The bladder having been previously emptied by the catheter, I opened the cavity of the peritoneum in the median line for a distance of four inches, terminating about an inch above the symphysis pubis. When the peritoneum was opened, there was an escape of some bloody serum; no fecal odor was perceived. The intestines presented somewhat distended with gas, and of a reddish hue; no other discoloration was observed at any time during the operation.

Passing my hand into the cavity of the abdomen, the transverse colon, from its commencement onward, was found bound down to the abdominal wall by adhesions; these were broken away without difficulty. On the left side, apparently stretching over the upper part of the sigmoid flexure, was a band, which was also broken away by the fingers. No other adhesions, or anything else abnormal, save the reddish congestion of the intestines, being observed either by Dr. Hamilton or myself, the wound was brought together by the interrupted wire suture. During the dressing of the wound, the condition of my patient was most alarming:

rule laid down, that in acute cases the lesion is to be looked for, in the small, while in what we term the chronic cases it will be found in the large, will in the main be found true. The symptoms also which should belong to each class we also find clearly tabulated; but in practice how often are many or all these symptoms presented in a single case, so that all the acuteness of the most skilled diagnostician fails to disentangle them, or read them aright, so that he can clearly say that the lesion is alone situated in one or the other intestine, or its exact nature. Should the case be one in which it was clearly evident (and these we often meet with), that the source of obstruction is situated in the large intestine, and which medical means fails to relieve, we believe the operation indicated is lumbar colotomy; while if the lesion is situated in the small intestine, or its locality be shrouded in mystery, medical means having failed to afford relief within twenty-four or forty-eight hours, according to the gravity of the case, laparotomy is called for, or perhaps a more simple mode of procedure may first be employed, and with prospect of success, if *too much* valuable time has not been given to medical efforts alone, viz., the tapping the intestine with a fine trochar, and thus relieving their distention by gas.

In a short paper like this it is not necessary to cite all the objections that have been urged against surgical interference; these have been too recently and ably answered by both Drs. Whitall and Ashhurst in their papers already alluded to.

Perhaps, however, some of the more cogent objections against operating in the minds of many are these:

First. That they have known cases of intestinal obstruction existing for very many days to have recovered under medical treatment alone.

Second. That the operation itself may provoke or convert an already local peritonitis into a general and fatal one.

Third. The shock from the operation will be too great for a patient already prostrated to bear up under.

Fourth. That after opening the abdomen we may fail to detect the source of trouble, or if found, to relieve the same, since autopsies in some cases have shown the difficulties to have been such as art could not have removed.

As to the first objection—that cases have recovered which had existed for many days, and when patients seemed to have arrived at the last gasp, is undoubtedly true. But if these comparatively few cases are compared with those many that die in spite of the best medical aid, the ratio of successful cases will, we think, compare most unfavorably with the results that have followed operations. We are informed by the statistics of the late Dr. W. Brinton, that from 12,000 post-mortem examinations, taken promiscuously (excluding hernia), that death from intestinal obstruction occurred in one out of 280 cases; and I feel pretty confident that the recoveries following obstructions caused by bands, or from the intestine being strangulated by becoming engaged in an opening in the mesentery or omentum, or from a twist of the bowel—medical means alone being used—*must be extremely rare*.

As to shock. The shock of the operation will no doubt in some instances be great, yet in the three cases operated upon in this country in the persons of negroes who were already greatly prostrated, the shock was but slight, and rapid recovery followed; and even in cases of ovariectomy in persons whose vital powers are greatly depressed, recovery is often the result. If we wait till the vital powers are depressed to their utmost from any cause, what operation, however simple, stands a fair chance of offering relief.

With reference to exciting peritonitis. That we have to encounter this risk is true, but the danger perhaps has been exaggerated, and in the majority of cases of obstruction, I think, if peritonitis exists at all, it will be found local and not general; and this is never a bar against the operation for strangulated hernia, but only prompts us to give speedy relief by the knife.

If the final objection we have mentioned should prevent the operation, it might as well also prevent operations for the relief of hernia, ovarian tumors, or stone.

Even in those cases where the adhesions are multiple and intricate, and where it would evidently be impossible to relieve the same, we do not think that by an explorative operation carefully performed, the condition of the patient could be rendered much worse; and the true nature of the case in this way could alone be determined, and we should have the satisfaction of having given every chance for life.

With regard to the nature of these obstructions we find from Brinton's statistics that out of 600 cases of intestinal obstruction, 31 per cent. were from bands, 43 from intussusception, 17 from stricture, and 8 from torsion. "When we have the history of an old hernia," says Mr. Bryant, in his work on surgery, "the probabilities of the existence of a band are much enhanced, for it is true that with hernia such bands are not uncommon." Such cases are given by Duchaussoy in his paper on intestinal obstruction (*Mém. de l'Acad. de Méd.*, 1860). Pagge gives one in his paper (*Guy's Hosp. Repts.*, 1869), and Mr. Bryant relates three cases in his own practice: one died unrelieved; in the second he opened the hernial sac and enlarged his incision upwards for about two inches, so as to detect a band high up in the abdomen; this was divided with a pair of scissors, and a perfect recovery took place. The third died after the operation, but the band was divided, and a large coil of intestine released. The operation had been put off too long. (*Bryant's Surgery*, Am. Ed. p. 296.)

Let us examine for a moment the results of this operation of laparotomy, and when we take into consideration the unfavorable circumstances in *very many* instances under which it was done, its success is certainly great. Adeiman in 33 cases (including all forms of obstruction) gives 15 recoveries and 18 deaths.

Whitall has tabulated 33 cases, and by a carefully prepared table shows and states "that when the conditions were as favorable for an operation as one could reasonably expect in a disease of such great fatality, *one hundred per cent. were saved; whereas, without such interference, every one of these must unquestionably have died.*" Under favorable conditions he justly classifies "all those cases in which the patient was not greatly exhausted, and in which there existed no serious abdominal obstacle, as extensive peritonitis, gangrene, perforation, insuperable occlusion."

Ashhurst, in a collection of 57 cases for acute intestinal obstruction for other causes than intussusception, operated on under all conditions, gives only 18 recoveries, a mortality of over 68 per cent., but states that, "in cases of strangulation by a fibrous band or diverticulum, or of protrusion of the gut through an aperture in the mesentery, the patient is, humanly speaking, inevitably doomed unless saved by the knife."

In 13 cases where the operation was done for invaginated bowel, there were 5 recoveries and 8 deaths. The only cases in which it has been resorted to during the first year of life have all terminated fatally.

If we look at the number of operations that have been done in our own country, we find that it is still,

indeed, in its infancy. I can find reports of but six cases where laparotomy has been resorted to for intestinal obstruction, mine, I believe, being the first case in this city. The cases are as follows: Dr. John R. Wilson, Tennessee, Dec., 1831, for old adhesions (*Transylvania Jour. of Med.*, 1835, p. 486); Dr. J. E. Manlove, July 7, 1844, for strangulation by old adhesions (*Bost. Med. and Surgical Jour.*, vols. 32 and 33, 1845); Dr. Thomas Wood, Dec., 1853, for strangulation persisting after reduction of hernia (*Western Lancet*, vol. 14, p. 720, 1853); two cases by Prof. Gross, of Philadelphia, for volvulus, reported in Ashhurst's paper, but dates and place of operation not given. The sixth case is my own, given in this paper. The first three occurred in the negro, and were all successful, the last three being fatal.

These statistics, I feel sure, are far more favorable than the majority of the profession imagine who have not carefully studied this subject, and the operation is one which no doubt should be more frequently performed than it has heretofore. That it, like all major operations in surgery, has great obstacles to contend against before it receives its proper high and established position among those that are justly sanctioned by the profession, I am fully aware. But I firmly believe that the day will come when the operation is more frequently and sooner performed, and then our knowledge and experience with this operation will make its results brighter, and from the knowledge which we obtain from our cases and the skill obtained in operating, it, like ovariectomy, will grow more and more in favor with the profession. No surgeon in cases of hernia reduced *en bloc* hesitates to lay open the cavity of the peritoneum, if necessary, and divide the constricting bands. Then why in other cases of grave internal obstruction hesitate to explore the abdominal cavity?

I have alluded to the tapping of the intestine as a means of affording relief in these cases. This operation certainly has neither the risks nor the gravity of laparotomy, and it has frequently been done in other cases, and that with impunity, and perhaps in some cases should at first be tried. If there is great tympanites it will certainly afford great relief to the patient, as we have verified in other cases.

Now, if the cause of obstruction be due to the intestine passing under a band, or into an aperture in the mesentery, or if it be due to a twist of the bowel, and the intestine be relieved of its distention by the escape of gas, may we not regard it possible that it will recover itself, and by its vermicular action it may be drawn out of its entanglement, especially if too much time has not been given for it to contract adhesions, and thus bind it in its abnormal situation. This happy result we know has followed such treatment in some cases of hernia.

Though this may be a means given us in the treatment of some of these cases by the advancement of our art, we should not advise long delay after its use, unless the symptoms contra-indicated it, before resorting to an explorative operation.

While thus advocating laparotomy in many of these cases, I do not wish to be understood as spurning medicinal means—far from it. But after these have been fairly and judiciously tried, and relief has not followed in two, three, or four days, all the circumstances of the case, of course, properly being taken into consideration, then I believe that some one of the operations referred to in this paper is peremptorily called for. And in this statement I think I shall be borne out by both the past and future history of these cases and the results furnished by operation.

THE DIFFRACTION SPECTRA OF COLORED FLUIDS.

By HENRY G. PIFFARD, M.D.,

NEW YORK.]

Two years and a half ago I conceived the idea of studying the absorption spectra with the diffraction grating instead of with the prism, and as soon as I was able to obtain the necessary apparatus put it into practice. During the past eighteen months a portion of my leisure time has been occupied in these pursuits. The advantages of the grating over the prism are fourfold. First, the grating gives a normal spectrum; that is, the different rays occupy their natural position in the spectrum according to their wave lengths, while in the prismatic spectrum the rays at the red end are crowded together, and those at the violet end widely separated. Second, with the grating the position of absorption bands can be indicated by the expression of the wave lengths absorbed, a matter determined by an easy calculation, which possesses many advantages over the arbitrary scale employed in prismatic observations. Third, amplification of the spectrum to any desired extent can be readily obtained with the grating, but in prismatic work it can only be effected by changing the eye-piece or prism, or adding additional prisms. For instance, a given spectrum may be brought under examination with double, treble, or quadruple the amplifying power in less than five seconds, without inconvenience, and without altering any of the adjustments of the instrument; the same cannot be accomplished with any prismatic arrangement without much greater loss of time. Fourth, with a grating the ends of spectrum may be reversed; that is, the red may be brought from the right to the left, or vice versa, in another five seconds, without disturbing any fixed adjustment. To accomplish this with prismatic arrangement (except in certain micro-spectroscopes) would involve a half hour or more, and many laboratory spectroscopes (*e.g.*, Desaga's) will not permit this change to be made at all.

Diffraction gratings may be constructed of fine wires placed close together, but not touching and parallel, or of a polished metallic surface upon which fine parallel lines have been ruled with a diamond, or preferably for the subjective study and measurement of the absorption spectra, of a piece of plane parallel glass, from $\frac{1}{16}$ to $\frac{1}{8}$ of an inch in thickness, similarly ruled.* The one which I myself employ is a piece of glass with parallel faces about $\frac{1}{8}$ of an inch thick and $1\frac{1}{2}$ inches square. It is ruled with 4,320 lines to the inch, and at the margin is the name of L. M. Rutherford.

If now the axes of the collimating tube and of the observing telescope be made to coincide, and if the grating is properly placed between the collimating lens and the objective of the telescope, a beam of light passing through the slit will correspond to the centre of the eye-piece, and the observer upon focusing will simply perceive a narrow line of light opposite the cross wires. If the telescope be now turned either to the right or to the left, the bright line is lost, and we find a dark interval, which, upon further movement of the telescope, is succeeded by a spectrum. On further turning this spectrum disappears, another dark space succeeds, succeeded by another spectrum, longer but less intense than the first, and so on until several additional spectra have been brought into view. If we return to

* Ranvier (*Journal de l'Anat. Phys.*, 1874) has constructed a diffraction spectroscopie from the sartorius of a frog, the transverse striations causing the diffraction.

the starting-point (the narrow line of light), and turn the telescope in the other direction, the same succession of spectra appear, with this difference, that if in the former instance the red end was to our right, it is now to our left.

which corresponds to natural number 5890, hence λ , or wave-length of D line, is 5890 ten-millionths of a millimetre.

As the line D, according to Angstrom * and other physicists, includes wave-lengths 5889-5895, the above

Fig. 1.—Diffraction Spectrum of Solar Light.

The first spectrum which is brought into view after leaving the starting-point is called the spectrum of the first order, and it is the one which will be found most generally useful in absorption work; the others are called spectra of the second, third, etc., orders.

Now, if we bring the telescope opposite the first spectrum, and solar light is employed, we will see the Fraunhofer lines occupying the positions shown in Fig. 1.

For comparison I introduce a diagram of the prismatic spectrum, Fig. 2.

determination is sufficiently close. θ in the above case is really a few seconds more than $5^{\circ} 45'$, but as the vernier of my instrument does not conveniently read to less than minutes I have assumed the value of θ as given. This error is of no practical consequence in absorption work as we are liable to others of much greater magnitude, from another source (indistinct margins of the bands), whether we work with gratings or prisms.

If we now place a dilute solution of blood before

Fig. 2.—Prismatic Spectrum of Solar Light.

It will be observed that the Fraunhofer lines occupy different relative positions in the two diagrams. In the former instance they occupy their normal or proper positions, in the latter abnormal positions due to the irrationality of prismatic dispersion.

the slit we will have the well-known absorption bands peculiar to that substance, but presenting a somewhat different aspect than when observed with a prism, as will be seen by comparison of diagrams (Figs. 3 and 4).

In the prismatic spectrum of oxyhemoglobin there

Fig. 3.—Prismatic Spectrum of Oxyhemoglobin.

With the grating the wave-length corresponding to any of these lines can be readily determined by the following formula:

$$\lambda = \delta \times \sin \theta$$

in which λ represents the wave-length sought, expressed in ten-millionths of a millimetre, δ the distance between the ruled lines of the grating, and θ the angle of deviation of the telescope when its cross wires are opposite

is a marked difference between the two bands, the band nearer the red being narrower and more intense than the other. In the diffraction spectrum these differences disappear in great measure, and the two bands resemble each other more closely.

If we apply our arc readings and vernier to the diffraction spectrum of oxyhemoglobin we will find, commencing at the red end—

Fig. 4.—Diffraction Spectrum of Oxyhemoglobin.

the line under observation. For example, in the grating which I employ I find by observation that θ is equal to $5^{\circ} 45'$ for the D line, $\delta = \frac{1}{4420}$ of an inch or $\frac{25.4}{4420}$ of a millimetre, which gives us:

$$\lambda = \frac{1}{4420} \times \sin 5^{\circ} 45'$$

Using logarithms we have:

$$\log. \lambda = \log. \frac{1}{4420} + \log. \sin 5^{\circ} 45'$$

$$\log. \lambda = .769303 + .000816 = .770119,$$

That absorption ends at $6^{\circ} 30' = \lambda 6655$
 That first band absorbs from $5^{\circ} 41'$ to $5^{\circ} 36' = \lambda 5822 - \lambda 5737$
 That second band absorbs from $5^{\circ} 23'$ to $5^{\circ} 15' = \lambda 5515 - \lambda 5379$
 That absorption again commences at $4^{\circ} 35' = \lambda 4697$

* Spectre Normale du Soleil. 1868. Upsala.

and continues to the end. Of course the limits of the absorption will vary with the strength of solution employed, and the centre of the band must be reckoned as its characteristic position.

Reduced hemoglobin in a somewhat more dilute solution than the one used above gave—

Termination of absorption at red end.....	6° 34' \approx λ 6757
Band.....	5° 33' to 5° 14' \approx λ 5686—5362
Commencement of absorption at blue end.....	4° 56' \approx λ 4544

I have here given a brief account of the diffraction grating, and of the method of using it as applied to the study of the absorption spectra, and in conclusion would advocate its use on the grounds that it gives a normal instead of a distorted spectrum, and affords a means of recording spectra which will enable the work of one observer to be accurately compared with that of another. There is, however, one disadvantage connected with the glass grating; we must employ a much more intense light than is necessary with the prism. I am in the habit of using for this work direct sunlight (sometimes condensed), reflected into the slit from a heliostat. At night I use a magnesia pencil rendered incandescent with the oxyhydrogen blow-pipe. For the magnesia pencil I am indebted to my friend, Prof. J. W. S. Arnold.

If desired, a small grating can be applied to the microscope, the upper part of the tube having a movable joint, and being provided with an arc of say 15° or 20°, with vernier. The necessary calculations for turning the observed angle into wave-lengths is exceedingly simple, one minute being a liberal allowance of time for each calculation. Unfortunately, good gratings are not yet a commercial article, and all American and most foreign observers who possess them are indebted to the liberality and kindness of Mr. Lewis M. Rutherford, to whom I take this occasion of acknowledging my obligations.

The grating is daily coming into greater prominence in connection with solar, stellar, and emission spectra, and as Prof. John W. Draper said twenty years ago, is the spectroscope of the future, and it is in the hope that those engaged in absorption work will be induced to abandon prismatic and adopt diffraction observation that these few lines have been written.

A CASE OF HIRSUTIES GESTATIONIS.

By CHAS. E. SLOCUM, M.D.,

DELIANCE, OHIO.

THE following case is so curious and rare that I furnish it for publication:

Mrs. R. has borne three children at full term, and suffered one abortion at six or eight weeks.

A peculiarity that has attended each gestation is the growth of beard on the sides of the face and under the chin. This hairy growth has uniformly started at the commencement of pregnancy, or become perceptible soon after the cessation of the menses, and continued until childbirth, and the uterus has assumed its anteconceived status.

Her attention is first called to the parts soon to be covered with hair by a sense of heat and itching, which is allayed but a short time by rubbing, and which continues about three months, with more or less annoyance, and then subsides to return again after accouchment and remain until the falling of the hair.

The hair is thick-set, fine and soft in texture, straight, and lighter in color than the hair of the head. Its length at childbirth is one to one and a half inches, when its growth apparently stops, and after a period of time varying from four to six months

(first child six months, second and third children four to five months), or about the time when the uterine system resumes its catamenial function, it falls, and the face assumes its normal smoothness.

This hirsute condition during gestation is the only peculiarity in this lady's history. She has uniformly enjoyed health. The menstrual flux was established when she was between thirteen and fourteen years of age, appeared regularly, and was attended with no peculiarity. From the age of fifteen to the time of her marriage, two years later, she suffered slightly from dysmenorrhœa, but not since marriage.

July 27, 1871, she gave birth to her first child, it being about one year after marriage; November 11, 1872, after one year, three and a half months, to the second; January 12, 1874, she suffered an abortion at one and a half or two months, experiencing but little trouble therewith, and November 13, 1874, ten months thereafter, her third child was born, apparently at full term, as it certainly was in full vigor.

At the time of her abortion the growth of hair on the face was very noticeable, and she became so soon again pregnant that the growth continued until the second conception was completed.

There has been nothing peculiar in the appearance of her children.

Mrs. R. is of medium height and size, with dark-brown hair, hazel eyes, and a fair skin, which becomes of a darker hue when she is in the pregnant state. There was but little nausea following conception, and she was vigorous and able to attend to her household duties at all times. No change or peculiarity other than that already noticed occurs.

This case, which must be classed as so rare as to be exceptional, is but another confirmation of what has long since become an axiom in obstetrics, that, "associated with the pregnant state, and dependent upon its continuance, are numerous manifestations which have their seat in organs so remote that it is difficult, in many cases, to trace the sympathy which exists between them and the special organs of generation.

"There is, in point of fact, no single function of the whole economy which may not be affected by the operation of a cause which has its centre in the generative organs, and which radiates thence throughout the entire system. Consequently, phenomena are frequently observed in distant organs, which are certainly not associated in function with the womb."

COMPARATIVE STATISTICS OF THE UNITED KINGDOM.

—A report has just been published, derived from the joint reports of the Registrar-General for England and the Registrar-General for Ireland, in which some remarkable comparisons appear. This is for the year 1872, at which time the population of England was 23,067,385 souls, and that of Ireland 5,368,696. In education Scotland ranks first and Ireland last. Illegitimacy is most prevalent in Scotland, less so in England, and least of all in Ireland. Of all the children born in Ireland only 2.5 per cent. were illegitimate.

In England the proportion of the deaths of males under five years of age was 41.49 per cent. In Ireland it was only 26.82 per cent. Out of 255,135 deaths of males in England, there were 195 of persons registered as being ninety-five years old and upward. In Ireland the total number of deaths was 48,091, but of these no less than 368 were returned as of persons over ninety-five years of age. There were seventy-five in England who had attained the age of one hundred, but in Ireland the number was 303. Lastly, in England there were 1,514 suicides, while in Ireland there were only 102.

Progress of Medical Science.

TREATMENT OF TUBAL PREGNANCY.—In the *New York Medical Journal* of last month Dr. T. G. Thomas reported an extremely interesting operation which he had performed successfully for tubal pregnancy, some months before. The plan of the operation was designed particularly to avoid the three great dangers—hemorrhage, peritonitis, and septicæmia—which have generally destroyed the success of all the operative means which heretofore have been employed to remedy this abnormal condition. The operations which have usually been practised are gastrotomy, in which the contents of the fetal sac are removed like an ovarian tumor; paracentesis, with evacuation of the fluid contents, in order to diminish the painful tension and arrest the growth of the fetus; and finally, destruction of the fetus by means of the passage of strong currents of electricity through the sac, or the injection into it of narcotic substances, etc. This last-named method usually results in the production of an abscess, after which the patient must rely on the chances of a spontaneous recovery. As stated by Thomas, the chief dangers of the first of these operations are peritonitis (which is involved in the necessity of cutting through the peritoneum) and hemorrhage. In the other two the dangers most imminent are secondary hemorrhage into the sac, septicæmia, and peritonitis. The following is Thomas's method of procedure: First, he avoids the peritoneum by opening the sac per vaginam. The opening is made with a knife, rendered incandescent by a strong current of electricity passing through the blade. By this means it was hoped to prevent hemorrhage from the vascular tissues by which the sac of an extra-uterine pregnancy is invested. To avert the danger of septicæmia the operation includes the removal of the entire fetal mass, and free drainage is afterwards maintained by the insertion of a tube of glass or silver, through which disinfectant injections may be made. The case in which this plan of operation was successfully applied was a tubal pregnancy of the left side, at about the end of the third month of its development. The patient was placed in the left lateral position, and Sims's speculum was introduced. The portion of the vagina lying directly beneath the sac was then made tense by two tenacula, one caught in the cervix uteri and the other in the vagina, on the left side. The platinum knife of the galvano-caustic battery having been raised to a white heat, was passed back and forth between the two tenacula until the sac was freely opened. Two fingers were then passed in through the aperture, and the operation of podalic version was performed, the fetus lying transversely. The body was readily delivered, but the forceps were applied to extract the head. Up to this point the plan, as at first proposed, had been followed precisely. The attempt to remove the placenta, however, was attended with such serious hemorrhage (forcible measures being precluded on account of the possibility of injuring the peritoneum) that a portion of the placenta was allowed to remain. T. had previously apprehended some difficulty here, for the reason that we have no definite knowledge of the mode in which the placenta is attached in tubal pregnancy. It was necessary to inject the sac with a solution of the persulphate of iron, which, while it controlled the hemorrhage, interfered with the perfect drainage which it was desired to establish.

Instead of the drainage tube a tent of cotton, saturated with carbolic acid and the persulphate of iron, was introduced and left in the sac. On the fourth day the tent was withdrawn, when symptoms of septicæmia developed but soon disappeared again under the use of carbolized injections. On the seventh day there was a slight hemorrhage, which was easily controlled; in another week the remaining portion of the placenta came away spontaneously, and thereupon the patient made a rapid and complete recovery. A slight abscess occurred in the arm, due to an embolus of an unimportant blood-vessel, and there were some incipient indications of phlegmasia dolens, which soon disappeared. Six weeks after the operation the opening made in the vagina had so completely closed that scarcely a trace of it remained.

Incidentally Thomas makes some suggestions concerning the pathology and the diagnosis of extra-uterine pregnancy. Thus he expresses the opinion that, while it is not yet a proposition susceptible of actual demonstration, "in the commencement of its development the impregnated ovum never attaches itself to or draws its nourishment from any other parts than those lined by the mucous membrane of the uterus or tubes." When the main attachment of the fetal sac is with a serous membrane or other non-mucous tissue, the relation is a secondary one.

Among the signs of extra-uterine pregnancy especial value is ascribed to that of ballottement. T. has seen four cases out of nine in the last seven years in which he was enabled to make a positive diagnosis by ascertaining the following conditions: (a) The existence of the gastric, mammary, and pelvic symptoms of pregnancy; (b) a uterus smaller than should exist at the supposed period of gestation; (c) a sensitive tumor to one side of or behind the uterus; and (d) pains extending from the pelvis down one thigh. In three of the four cases the sign of ballottement was very distinct.

TYPHOID FEVER AT LEWES, ENGLAND.—In the Report on Public Health, by Dr. J. W. Moore, it is stated that in Lewes, Sussex County, an outbreak of typhoid fever occurred in July and August, 1874. In the fortnight ending October 24th there were 197 fresh cases, after which the epidemic subsided. Altogether there were about 450 cases and 27 deaths, in a population of 11,000. So serious was the disease that the Assizes for Sussex were held at Brighton, and not at Lewes, the County town. Dr. Thorne was deputed to inquire into the causes of the epidemic, and he reports that the outbreak was distinctly traced to the water supply. It was found that among those citizens who were supplied with water from the public works, there were about five times more cases of fever than among those who were supplied from private wells. The pollution occurred in the following manner: Many water-closets were supplied directly from the mains, the water being admitted to the pans by simply turning a tap. These taps were constantly left open, so that when the water supply happened to be cut off, foul air was often sucked through them into the mains. It also appeared, from the inquiry, that the town water had been polluted by the accidental admission of foul tidal water into the water-works, in July—a circumstance which would explain the earliest cases in the epidemic. The direct service-pipes spoken of above existed in houses where the first cases of the fever occurred. The open pipe communicating with the mains passed into closet-pans containing the evacuations of typhoid fever patients, so that it was almost impossible that particles of the diseased evacuations could escape being drawn into the mains.—*Irish Hospital Gazette*, May 15, 1875.

POST-MORTEM EXAMINATION OF A CASE WHERE INFLAMMABLE GAS WAS DISCHARGED FROM THE STOMACH.—Dr. Ewald writes from Berlin, giving an account of the autopsy in the above case (see *Irish Hospital Gazette*, Vol. II., p. 254). The stomach was found but little distended, the pyloric orifice was imbedded in a hard tumor about the size of a walnut, and its calibre reduced to that of a crow-quill. The mucous coat of the stomach was pale and anæmic, and became gradually lost in the substance of the tumor. The serous coat of the stomach was everywhere thickened, especially about the pylorus. The tumor, on microscopic examination, proved to be a fibro-myoma. The glands of the stomach, except in the immediate neighborhood of the cardiac extremity, had completely disappeared, and the whole thickness of the mucous membrane was occupied by innumerable small, round cells, which had completely destroyed the regularly arranged stomachic glands, and but few such, widely scattered, could be found, in which no ordinary epithelium could be discovered.

Dr. E. says that the nature of the tumor explains the absence of any symptoms which, during life, are looked upon as indicating malignant disease, but that the presence of carburetted hydrogen in the eructations is still as great a mystery as ever. He says that though Kunkel has recently shown that during the pancreatic digestion a gas is evolved composed of carbonic acid gas, hydrogen, and carburetted hydrogen, and admitting that some of this gas might regurgitate through the pylorus into the stomach in a normal state of the opening, he thinks that the small size of the pylorus in this case is strongly against this view of its origin.—*Irish Hospital Gazette*, May 15, 1875.

TREATMENT OF NASAL LUPUS BY EXCISION.—Mr. John Gay recently read a paper on the above subject before the Royal Medical and Surgical Society, and stated that he believed lupus exedens was a topically malignant form of ulceration, and that the alleged cures of this affection by constitutional treatment were probably based either on errors of diagnosis, or on the inclusion under the generic term "lupus," of forms of disease with which, typically, it has no natural affinity or alliance. In discussing the differential diagnosis between lupus, epithelioma, and rodent ulcer, and the comparative values of treatment by caustics and excision in nasal lupus, he says that in using caustics, cicatrization, or an advance towards it, must be waited for before any plastic operation can be attempted to relieve the deformity, which is one of the most important objects in the treatment of cases of this kind. In the treatment by excision a plastic operation can be performed at the same sitting, and thus tissue may be saved, the loss of which would be unavoidable in the use of caustic. He relates three cases which he had treated in this way. In the discussion which followed, the galvanic cantry and the use of the solid stick of nitrate of silver were mentioned, but Mr. Gay, in reply, said that he merely wished to draw attention to the economy of tissue in the use of the knife, where plastic operations were necessary for relief of deformity.—*The Lancet*, May 29, 1875.

HEUBNER ON SYPHILITIC DISEASE OF CEREBRAL VESSELS.—Dr. Obersteiner has brought forward the following views of Prof. Heubner, as set forth in a recent monograph. According to this author, the arteries most frequently affected are the basilar, and those slightly smaller than it, such as the artery of the Sylvian fissure. Such vessels are said to have the following constituent elements. Internally there is an endothelial lin-

ing, next to it externally comes a tortuous membrane, the membrana fenestrata, then the layer of circular muscular fibres, and lastly the adventitia. The entire diseased process under consideration goes on between the endothelium and the membrana fenestrata. The first step in the change consists in the development, in the intermediate space, of cells which soon are seen to be spindle-shaped. These cells are presumed to be derivatives of the endothelium cells. Afterwards white blood-corpuscles make their way into the new tissue. This new formation now enlarges, and pushing the endothelium before it, soon diminishes the calibre of the vessel; the subsequent changes in it are such that ultimately a new coat is formed consisting now of three strata, but still occupying the space between the endothelium and the fenestrated membrane. This new coat may become organized or undergo various forms of degeneration.

Heubner believes that the results of injections of the brain have shown him that two vascular circuits must be distinguished, the difference consisting in the different modes by which the arterial trunks give off branches. There is the basilar circuit, comprising the principal branches distributed to the white substance at the base of the brain, and the cortical circuit beginning where these pass to the cortical substance, or rather to the pia mater. In the former, the small twigs leave the main branches at right angles and pass directly, without anastomosis, to the special tracts which they supply, thus constituting *terminal arteries* in Cohnheim's sense; while in the cortical circuit, the arteries divide into a fine network with numerous anastomoses, from which arise the vessels supplying the cortical substance.

If, therefore, one of these larger arteries is diseased as described above, and its calibre is obstructed so as to interfere with the blood-supply to the cortical part, this fact will be evidenced by attacks of unconsciousness, faintness, etc., symptoms which are due to the oscillations in the blood-pressure, but which will gradually be relieved when the equilibrium is restored by the collateral circulations, even if a large vessel remain obstructed. If, however, the stream of blood is interrupted in the other circuit, which has the terminal arteries, there will be infarction or softening, and, as the motor tracts are situated there, hemiplegias may be expected.—*Rundschau*, April 12, 1875.

ELECTROLYSIS IN NÆVI.—Mr. Knott, Medical Superintendent of Galvanism to St. Mary's Hospital, London, has reported forty cases of nævi successfully treated by the above method. He uses Stöhrer's and Meyer and Meltzer's continuous batteries, and judges according to the size of the nævus how many cells to use; six or eight is about the average if the battery be in good order.

He says that if the nævus be small, he uses one or two needles attached to the negative pole, and one to the positive, and passes them into the tumor; but if it be large he puts on several needles in the negative cord, and uses a charcoal point with the positive. After the needles have been in the tumor a short time decomposition begins to take place; this is shown by bubbles of gas passing by the side of the needles. A clot is then formed, the tumor turns of a bluish white, and in this clot fibrous degeneration takes place, and an ultimate cure is the result. The advantages of the galvanism are its certainty of action, its safety, the faintness of the cicatrix, and the cessation of pain directly the operation is over. He has used every other method, and thinks this by far the best.—*The Lancet*, March 20, 1875.

New York, July 10, 1875.

THE ORIGIN OF PUERPERAL FEVER.

THE questions involving the nature and causes of the fevers associated with childbed have always been matters of great interest and importance to practitioners, but they are now receiving increased attention, from the fact that these diseases have of late years been remarkably prevalent, and also because there has been shown a tendency to connect their spread with personal contact on the part of the attendant. The serious consequences which the propagation of the latter opinion may at any time bring upon the most deserving practitioner have become so apparent that the Obstetrical Society of London has undertaken to institute inquiries on these and other points, and the results they have thus far reached give promise that some of them will be answered definitively.

When the debate was opened by Spencer Wells, he submitted the subjoined six propositions, which were designed to cover the main points of inquiry, and which he hoped would elicit the required facts. His hopes seem to have been partially realized, and many of the ablest obstetricians in Great Britain have come forward and expressed their views, while data of hardly less value have been supplied through the journals from the individual experience of many general practitioners. The propositions are as follows:

1. Is there any form of continued fever, communicated by contagion or infection, and occurring in connection with childbirth, which is distinctly caused by a special morbid poison, and as definite in its progress and the local lesions associated with it as typhus or typhoid, scarlet fever, measles or small-pox?

2. May all forms of puerperal fever be referred to attacks of some infective continued fever—as scarlet fever or measles—occurring in connection with childbirth on the one hand; or, on the other, to some form of surgical fever, or to erysipelas, caused by or associated with changes in the uterus and neighboring parts, following the process of childbirth?

3. If all cases of contagious and infective diseases which occur under other conditions than that of childbirth are set aside, does there remain any such disease as puerperal fever?

4. Assuming that a form of continued fever, communicated by inoculation, contagion, or infection, does frequently occur in connection with childbirth, how can its spread in private or in hospital practice be most certainly prevented or checked?

5. What relation have bacteria and allied organic forms to the pyæmic process in the puerperal state?

6. What is the value of antiseptics in the prevention and curative treatment of puerperal fever?

We publish these queries to give a still wider circulation to them in the hope that they will attract special attention in this country and elicit further facts. The recent conviction of a midwife, in England, of manslaughter, has shown that the matter is of the very first importance. The midwife was convicted on the ground that she had induced the disease among some of her patients by conveying it on her person from those infected, thus disseminating it.

If the midwife was justly condemned, it was upon the assumption that the disease in question was positively conveyed by her. The same reasoning might, however, apply in the case of any medical practitioner in whose practice a case of puerperal fever broke out.

That the disease, however, does not always so originate seems to be evident from the citation of cases which the discussion has evoked, for it has been shown that puerperal fevers, or diseases which pass by that name, can originate where there has been no contact of the woman in confinement, either with the person of the accoucheur, his clothes, or instruments, and, in fact, where no attendant has been present.

We have it also on the best authority, from a personal inspection of the records in this city, that puerperal fever, which is so apt to be ascribed to that mysterious something which has been called *hospitalism*, is actually more common in private practice than in hospitals.

In our large cities and towns, however, it is extremely difficult to divest any disease of all the possible factors that may be regarded as sufficient to produce it. We have often the presence of various epidemic diseases, such as typhoid, typhus, scarlet fever, and the like, which with some would be regarded as sufficient to call out puerperal fever in a parturient woman. Then there is the presence or personal contact of the attendant, while in other cases, we have want of cleanliness, bad ventilation, or neglect of sanitary attention to the premises. In other cases, the patient herself may not have received the proper topical applications to the injured parts. These and other causes would be thought by some sufficient to induce the disease.

In country practice we are far less apt to have such a combination of possible factors, for the country practitioner is apt to be called to see cases where there

is a total absence of many of the conditions just mentioned, and he may therefore have an opportunity of narrowing down the probable cause to a comparatively small number of possibilities. To him, therefore, we shall have to look for assistance in securing evidence upon these points, and from a large number of such data we shall probably succeed finally in finding the actual cause or causes. The value of determining these questions can hardly be overestimated, for in the event of suits at law, ignorant or malicious men are now in danger of causing serious damage to the practice or reputation of any medical man who is unfortunate enough to have a puerperal fever break out in a patient under his care.

HOMŒOPATHY IN MICHIGAN UNIVERSITY.

THE establishment of a homœopathic college as a branch or department of the University of Michigan will, we doubt not, be a source of considerable embarrassment to the present medical faculty of this excellent school. An attempt is being made on the part of the Regents to appoint one or two homœopathic professors, ostensibly to take charge of the new department, but in reality to become by law members of the faculty. This will certainly be an original method of forcing disagreeable and unprofitable associations, which will be resisted by every one interested in the prosperity of the school.

There is only one course for the Regents, and that is the establishment of an independent homœopathic school.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 12, 1875.

DR. F. DELAFIELD in the Chair.

MULTIPLE ABSCESS OF THE LUNGS, FOLLOWING CASEOUS OSTIIS OF THE HEAD OF LEFT THIGH-BONE.

DR. GIBNEY presented the remnant of the head of a femur which has been the seat of a caseous ostitis, and of itself presents nothing specially interesting. The history of the case, however, with the complications attendant thereon, will, I hope, bring before the Society the following important points:—

1. The etiology of morbus coxarius.
2. The metastasis of strumous disease.
3. The connection between caseous abscess and the development of tubercle.

Without any extended remarks on the views of well-known pathologists, I shall briefly recite the history as obtained from the mother (a woman of moderate intelligence), and the observations hastily made at the necropsy.

The patient, a male, seven years of age, living in Harlem at the time I was called to visit him, April 15 of present year. He was lying with both thighs flexed on body, left leg flexed on thigh, right leg semi-

flexed. The accommodations of the sick chamber and the excessive peevishness of the boy made a thorough examination impracticable. Superficially, I observed a well-marked hippocratic countenance, a head unusually large, and of the "Bombay" type; a respiration of 30 to the minute; small, frequent pulse; a body greatly emaciated over the bony structures, while the abdomen was moderately distended by an enlarged liver; both lower extremities œdematous—the right easily extended, while the left could not be extended beyond an angle of 135°; motion at right hip perfect, at left limited by an *apparent* contracture of the adductors and flexors. A tumor, extending from the troch. major to the internal condyle of the femur, attracted especial attention. The integumental covering seemed intact, and no distinct fluctuation could be perceived. The right ankle was studded with several openings, some of which presented ulcerated borders.

The little fellow's history ran somewhat as follows: The second of three children, all of whom were in a state of health far below the normal standard. Father died at age of 36, of phthisis pulmonum, following, six months distant, a form of insanity, for which he was confined in the Flatbush Asylum. Both the insanity and phthisis, it is fair to say, developed two years subsequent to the birth of this child. A paternal aunt died of phthisis. The mother has been choracic from girlhood. Maternal grandfather died in the Insane Asylum, Blackwell's Island. A maternal aunt is at present insane.

With the exception of a slight herpetic eruption about nasal orifice, the child was considered healthy up to the third summer, when a colliquative diarrhœa set in, and "consumption of the bowels" was the diagnosis stated to the mother. For months following this a peculiar awkwardness in the gait was noticed. Finally, recovered completely, and during the summer of 1872—then four years old—fell from a railing, and on the *next day* complained of a pain in the left knee. This pain soon subsided, and nothing save a slight limp on extra exertion was observed for the next six months. Then the "starting pains," gradual change in position of limb, and tenderness, induced the mother to consult a physician. From that time to April of the present year various physicians treated the case. Two or three blisters were applied with no relief. Deformity increased. Abscess formed within five months after the first medical interference. In March, 1874, the right ankle suddenly took on severe inflammation. Abscess speedily formed, and opened spontaneously. All active symptoms at the hip subsided, and the cold abscess remained *statu quo*. Shortly after the invasion of the ankle lesion scarlatina supervened, and was followed by œdema of lower extremities. Chorea followed in the wake of the scarlatina. This terminated in a few weeks.

After I saw the case I examined the urine frequently, and found no albumen and no cast—only a low specific gravity. Tonics and stimulants were used freely with no effect. Death by asthenia May 5th.

At the necropsy, twelve hours afterward, I was assisted by Dr. T. H. Skinner, and we were limited to the thorax and abdomen, and the hip.

Extensive adhesions of pleura on right side—few on left. Abscess near apex of right lung, 1 inch in diameter. Several smaller ones throughout, some cheesy, some containing pus. At the base of left lung was an abscess 2 inches in diameter. Liver about one-fourth larger than normal. No caseous patches found on section. Kidneys normal in size; markings perfect.

On opening tumor on thigh, a large quantity of caseous material was removed—no fluid whatever.

Sac 10 inches long by five wide—traced to posterior surface of capsular ligament, which was perforated at that point, otherwise intact. Acetabulum roughened, not perforated. Shaft of bone unaffected. A small portion of head removed. Right ankle not examined.

The hereditary dispositions and the character of the inflammatory processes point towards a strumous origin. The history of the fall is in close connection with the invasion. The pulmonary lesion seems unquestionably to have followed the formation of the cold abscess on thigh.

Two joints were actively inflamed at successive periods. I have given the facts, and my regret is that the autopsy could not have been made with more care, and on retrospection I find many interesting points which I might have observed with profit. As far as treatment was concerned the result speaks for itself.

TUMOR OF ANTRUM.

DR. A. C. POST presented a tumor of the antrum, removed, a number of months ago, from a man aged forty-five years. The mass was of slow growth, first making its appearance about ten years ago. The patient's general health was good, and the tumor had the feeling of a soft mass enclosed in a thin bony shell. The operation was performed in the usual manner. The roof of the orbit was not involved in the disease. The tumor was examined microscopically by Dr. Satterthwaite, and proved to be sarcomatous in character.

DR. DELAFIELD remarked that there was some law concerning the recurrence of tumors of the antrum which was not explained by their microscopical character. For instance, the sarcomata would present precisely the same microscopical elements, the same anatomical relations to each other, and yet in one the growth would reappear in a short time, and in another there would not be a recurrence for years.

DR. MASON remarked that he had, four years ago, presented a specimen of myeloid tumor of the superior maxilla, involving the orbit, but in which there had been no return of the disease up to this time.

DR. SATTERTHWAITE referred to a tumor of the lower jaw which he had presented three years before. The disease was a sarcoma, and was surrounded, as in Dr. Post's case, with a thin shell. For two years the patient had no return of the disease.

CHRONIC ALCOHOLISM.

DR. JACOBI presented a heart removed from a female patient of Bellevue Hospital, who entered that institution a number of weeks ago with the symptoms of chronic bronchitis, emphysema, and an attendant cyanosis, and who died about six or eight days afterwards. During her stay in the hospital she was relieved for a time of her more urgent symptoms, the dyspnoea and cyanosis disappearing until just before her death. She had been a hard drinker, her favorite beverage being Holland gin, to which she ascribed many remarkable curative properties. At the autopsy her lungs were found in a state of chronic bronchitis, pulmonary infiltration, and emphysema; at the same time there was cirrhosis of the liver.

The heart, contrary to expectation, was not enlarged, but in the condition of fatty degeneration due to the chronic alcoholism with which she was affected. The point of interest centred in this condition of the heart connected with the urgent dyspnoea and cyanosis, which were prominent symptoms in her case.

Dr. Jacobi also exhibited a specimen of cysticercus of the liver which was removed from a patient of Bellevue, of whose history he was at the time of presentation ignorant. The cyst was situated in the substance of the organ, and was evidently at a standstill, its contents being very much thickened and the cyst-wall having undergone ectaceous degeneration. The fluid contents contained an immense amount of cholesterine and some hooks of the *echinococcus*.

PSEUDO-ENCEPHALUS.

Dr. Jacobi lastly presented a specimen of pseudo-encephalus, for which he was indebted to Dr. Samuel B. Ward. The specimen was a fœtus which had evidently been expelled during the seventh month of utero-gestation. There was an entire absence of the cranial bones, except the arches of the frontal and temporal bones. In place of the brain there existed a mass divided by a groove, which marked the location of the falx, in the cavity of which were a few layers of brain-tissue. The mass itself consisted of immensely dilated blood-vessels, surrounded by a large amount of new tissue, and also by a tissue which might be taken for dura mater. The spinal canal was entirely open, and contained nothing but connective tissue. Dr. Jacobi was of the opinion that the anomaly was caused by an inflammation of the brain and spinal cord, which had taken place at an early period of utero-gestation, and which, by the attendant effusion, not only interfered with the development of the cerebro-spinal system, but prevented the development and closing of the cerebro-spinal arches. The spinal nerves were found intact, thus proving the statement of Sayre, a French embryologist, that the development and growth of the nerves have nothing to do with their respective nerve-centres.

INTESTINAL OBSTRUCTION—LAPAROTOMY.

DR. ERSKINE MASON presented a specimen of intestinal obstruction, for the relief of which he had performed an operation (*vide* page 465).

DR. LOOMIS remarked that this was the third case he had seen in which at the autopsy the obstructions had been found in the small intestine. From what he had seen of the other cases, he was of the opinion that peritonitis existed at the time the consultation was held, and that any operation for the relief of the patient would be useless.

DR. MASON remarked that had the band which extended from the Fallopian tube to the ileum been detected, it could have been divided without injury. The real difficulty was in the adhesion of the adjoining portions of the intestine, which made it impossible to straighten out the same.

DR. JACOBI remarked that most of our reasoning in these cases must be theoretical. This being the case, he believed it would be safer and better to remove the intestine from underneath the constricting band, rather than run any risk of exciting peritonitis by tearing or cutting these constrictions.

DR. MASON stated that in his case, on account of adhesions of different portions of the gut, such a procedure was impossible.

DR. POST did not see why the bands in question could not be divided with as much safety in these cases as in those of strangulated hernia. The difficulty, however, would be in diagnosing their precise situation and extent.

DR. JACOBI believed that a diagnosis could generally be made with some degree of certainty in ordinary cases. When there is vomiting very soon after anything is swallowed, and this vomiting is not stereo-

raceous, the obstruction is apt to be high up—in the small intestines. Such a diagnosis can be further confirmed by the occurrence of numerous passages after an obstruction is supposed to exist.

DR. LOOMIS, in this connection, remarked that almost all the old adhesions were to be found in the small intestines.

DR. MASON stated that fully 95 per cent. of the cases were in that category.

THE RELATIONS OF ERYSIPELAS AND PERITONITIS.

DR. LEWIS SMITH presented a specimen removed from the body of an infant, which died at the age of seven weeks. It had been an inmate of an infant asylum of this city, and was wet-nursed by a woman who was attacked with erysipelas. The child, previous to this occurrence, did well, but soon after had a profuse discharge from the bowels with vomiting, and died within three days afterwards.

On post-mortem examination the thoracic organs were entirely healthy. On opening the peritoneal cavity about half an ounce of rather thin, curd-like liquid escaped. About the same quantity of thin, purulent-looking fluid remained in the pelvic cavity. The peritoneum throughout a considerable portion of its extent was congested, and there was fibrinous exudation over the liver and the spleen. The points of interest in this case had reference to the practicability of allowing a child to nurse a mother when affected with the disease in question, and also in establishing the relation of the peritonitis of the child to the erysipelas of the nurse.

IDIOPATHIC ENDOCARDITIS.

DR. DELAFIELD exhibited specimens taken from a young man, aged twenty years, who was admitted to Roosevelt Hospital, three days before his death, in a very feeble, emaciated condition. So far as could be learned, he had been half starved, and a good deal of his condition was apparently due to that fact. He was, however, able to state that two years before he had been attacked with severe headache, accompanied and followed by delirium; that this attack was so severe that he was confined to his bed for two weeks. He recovered from this, but he had a number of similar ones during the succeeding two years. At one time he was under treatment in the hospital for perineal abscess. Dr. Delafield did not see the patient during life, and was not aware that any diagnosis had been made.

At the autopsy the heart presented an unusual good example of acute endocarditis affecting all the valves; also a small amount of acute pericarditis. There were old and recent infarctions in the spleen and in one kidney. In the middle cerebral artery was an embolism, apparently proceeding from the heart. There was no brain softening accompanying this condition. On the same side of the brain—the lateral surface of the left anterior lobe—the dura mater was very considerably thickened. The brain beneath is depressed and softened, and the cortical matter in that position is atrophied. On removing the dura mater from the brain there were slight recent adhesions over the entire surface.

The question concerning the probability that a gonorrhoeal rheumatism might have had something to do with the brain lesions, came up, but Dr. Mason, who had charge of the case at the time of the perineal abscess, stated that when he left the hospital he had no symptoms of the complication in question.

Adjourned.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 17, 1875.

DR. S. S. PURPLE, PRESIDENT, in the Chair.

SUCCESSFUL TREATMENT OF CICATRICIAL CONTRACTION FOLLOWING BURNS.

DR. GURDON BUCK presented a case of this character in a lad seven years of age who was admitted to the Presbyterian Hospital in March, 1874. When two years old he received a severe burn, which left an extensive contraction, involving the right axilla and arm. When the arm was elevated to the horizontal position—the limit of elevation—a fan-shaped fold of skin was brought into view, occupying the axilla and extending from the ninth rib to the elbow. When it joined the arm, near the elbow, it was prolonged over the forearm to the wrist in the form of a thickened cicatricial ridge. The fan-shaped fold corresponded to the anterior fold of the axilla, while the posterior fold of the axilla exceeded but little its normal dimensions, and between that and the anterior fold, stretching high up into the axilla, was a deep recess. The elbow and shoulder joints did not suffer, and were only restricted in their motions by the contractions of the integument. The first operation was performed a few days after his admission to the hospital, and consisted of transfixing the fold, high up towards the shoulder, and severing it from its connection with the arm along the line of junction. This at once set free the arm, and the separated fold receded and spread out over the thorax. The farther step of the operation consisted in excising the portion of cicatricial tissue extending down to the wrist, and wherever any resistance was offered to complete extension of the arm and forearm, the edges of the constricting bands were divided until sound tissue was encountered. In this way a complete liberation of the limb was procured. At certain points the edges of the wound were stitched, not with the view of obtaining adhesions, but rather to keep the parts in shape and place, and the extensive raw surface now exposed was covered with the following dressing: First cover the surface with a layer of soft scraped lint, and over that place layers of ordinary sheet lint, applied in broad stripes, saturated with collodion. Shingle the surface in with these strips, allowing their ends to go well over upon the surrounding parts. This dressing hardens very quickly, and forms an artificial scab. It has been uniformly observed that only very little swelling and redness follow this dressing in the neighborhood of the wound, and the artificial scab remains adherent from six to ten days. In the meantime at one or more points there will be an escape of fluid at the margin of the dressing, not precisely of the character of pus, by means of which it is gradually detached, and is then removed. When removed it will be found that suppuration has been retarded, and the raw surface has become covered with healthy granulations, usually filling it up to a level with the surrounding skin. One great advantage of this dressing is, that it affords rest for the wound for the first few days, and so much is added to the comfort of the patient and the convenience of the surgeon.

The next point in the treatment of the case consisted in maintaining the limb in the new position. This is an essential part in the management of these cases, namely, maintaining the limb constantly in the restored position in which it is aimed to place it. This is effected, according to the part involved, by such apparatus as is best adapted to afford the greatest possible degree of comfort to the patient, and yet fulfil the indication mentioned.

In the progress of healing it will be necessary to repress the exuberant granulation growth, and that is most effectually done by applying, perhaps, at the end of two weeks, adhesive plasters an inch or more in width, in immediate contact with the raw surface, and extending beyond the wound a sufficient distance to sustain the pressure desired. There is no more efficient method of maintaining a smooth condition of the granulating surface, and with this it may also be necessary to make use of caustics. In using caustics, nitrate of silver being specially referred to, he had found it necessary to do more than simply pass the stick over the surface of the granulations, and has found the growth best repressed by spading or boring the point into the surface at places in close proximity with each other. Occasionally solid caustic potash may be necessary, and if used great care must be taken in surrounding the wound with some absorbing substance for the protection of the unaffected tissues.

The gain effected by the first operation was considerable; in the summer following all support was removed from the arm, and certain gymnastics were practised which had a tendency to straighten the limb. In December following a second operation was performed, mainly of the same character as the first. All cicatricial contractions were again divided, and, in addition, incisions were made at a little distance from and parallel with the edges of the wound, which were also left to heal by granulation. Treatment was the same as after the first operation.

The third operation was performed about one year from the time of performing the first, and was trifling as compared with those which preceded it. The tendency to relapse is very persistent in these cases, and requires to be resisted for a very long time. The boy can now flex, and extend, and otherwise handle the limb as well as the sound one. To assist in holding the axillary fold up in proper position, axillary rings, stuffed with bran, had been slipped over each shoulder and fastened behind to each other by means of an elastic band. These rings were regarded as very efficient aids in overcoming the tendency to contract in the axillary fold.

MIGRATION OF PURULENT MATTER.

DR. BUCK also read a paper upon the above subject, in which he mentioned the anatomical and other conditions upon which it depends, as illustrated by cases. By migration of pus is understood its accumulation in a locality more or less remote from the seat of suppuration, and it may take place in certain regions of the body, and is favored by the anatomical relation of the parts involved, especially in membranous structures and aponeuroses, and also by gravitation.

Three cases were then reported in which the parietes of the lower abdominal and pelvic cavities were concerned.

The first case was a child, eleven months old, upon whom a swelling in the left groin and upon the left buttock appeared simultaneously. The pus was thought to have come from the region where the iliac vein crosses the brim of the pelvis. There was marked enlargement of the superficial abdominal veins. The second case was in a male, 24 years of age, in whom a tumor appeared in the hypogastric region, simulating in appearance a distended bladder. It proved to be a collection of pus, and it was supposed that it came from the left ileo-lumbar region, as the result of a previous injury. The third case illustrated the fact that the pus from diseased vertebrae may migrate through the obturator foramen, and make its appearance upon the inner aspect of the thigh among the adductor muscles.

Dr. A. C. Post, in remarking upon the treatment of these so-called "abscesses by congestion" of the French writers, spoke of the antipathy which used to exist, and does now, with regard to opening them. The more modern treatment, however, is to open them freely, instead of making the old valvular incision, and then use free antiseptic injections. In this way the discharge can be made much more complete and the danger from decomposition of matter exposed to the air is very much diminished.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

INTERMITTENT FEVER TREATED WITHOUT QUININE.

THIS treatment has been used in some of the hospitals in Europe, it is reported, with considerable success, but in this hospital that success has not been obtained which has been claimed for it, because it has failed to cure more than one out of three. In making up our estimate of the value of any plan of treatment we should take into consideration the fact that, in a certain number of cases of intermittent fever, the patients, without medicine, will not have chills after admission to any hospital. The simple change of residence effected in this way is sometimes sufficient to arrest the disease entirely, and at once. Moving a patient even from one malarial district to another will sometimes arrest fully developed paroxysms of ague, which have resisted all ordinary forms of treatment. The plan of treatment, independent of quinine, consists in the use of ergot, and Squibb's fluid extract was prescribed in drachm doses every four hours.

A FAVORITE METHOD OF ADMINISTERING QUININE FOR THE CURE OF AGUE.

Give a single dose three or four hours before the time for the occurrence of the chill, and of sufficient size to produce well-marked cinchonism within two hours after its administration. After that give enough to produce a trifle of buzzing in the ears and continue it daily for a few days, and then use the drug in smaller doses daily for two weeks.

EPILEPSY.

It has been said that this affection of itself involves necessarily more or less impairment of the intellectual faculties. In a majority of cases it is not the direct effect of the epilepsy. The explanation is this: a person who has epilepsy does not, as a rule, exercise the intellectual faculties as much as he would otherwise do, and this was regarded as the chief or entire cause of the general mental aberration seen in these cases. If this be true, it is an important point in treatment to insist that the intellectual faculties of the patient be regularly and reasonably exercised.

A POINT OF INTEREST IN PHYSICAL DIAGNOSIS.

When the patient opened his mouth a *puff* sound could be heard, which was synchronous with the heart-beat. There were satisfactory evidences that a pulmonary cavity was present just behind the base of the heart. When the chest wall was firmly compressed this *puff* sound at once disappeared, but returned the moment the pressure was removed.

The explanation given was that the heart impulse was communicated to the walls of the cavity with sufficient force to affect the air contained within it and

thus produce the sound heard. Such a sound can be very easily mistaken for a cardiac murmur.

ANGINA PECTORIS.

In this case there was aortic regurgitation, accompanied by visible pulsation of the radial, ulnar, temporal, and carotid arteries.

One feature of interest was the fact that the anginal symptoms, which at times were very severe, had uniformly been relieved with great promptness by the inhalation of the nitrite of amyl.

Another feature of interest was the presence of a mitral systolic non-regurgitant murmur.

Aortic regurgitation is necessary to its formation, and when a presystolic murmur is present it is very liable to be mistaken for a mitral regurgitant.

ACUTE ARTICULAR RHEUMATISM.

Pericardial inflammation had occurred in two cases while the urine was alkaline.

CHRONIC PLEURISY.

There are some points of interest in the following history, which began in the summer of 1874, when the man was admitted to the hospital, with the left pleural cavity filled with fluid. His previous history did not afford any evidence of pulmonary disease of consumptive nature. An exploring canula was introduced, and pus withdrawn; and then $\text{℥} \text{℥} \text{℥} \text{℥}$ were drawn off by means of the aspirator. The cavity soon filled again; and was again removed in the same manner as before; after which a free opening in the chest-wall was resorted to. The case is interesting in the fact that not so good results followed the free incision and daily washing out the pleural cavity as was expected. He did not do well, and yet it was difficult to tell why he did not improve, for the amount of pus discharged was not excessive, nor the amount of dyspnoea such as would account for a continued unfavorable condition. At one time he suffered from a severe diarrhoea, and it was then supposed to be probably of a phthisical character. Latterly, however, his improvement has been marked and progressive; and the benefit has arisen from approaching warm weather and going out of doors every day.

The case well illustrated the effect of hygienic measures in cases of protracted diseases, for since he had taken a ride upon the river daily his temperature, which previously had been every day or two dodging up to 102° or 103° , had fallen to near the normal standard, and remained there.

At one time his chest was washed out with a solution of quinine after the manner recommended in *The Practitioner*, but no other improvement followed than that which was regarded simply as coincident. His present condition is very good.

ANEURISM OF THE INNOMINATA.

There were several points of interest in the history of a case of this kind, which made it worthy of note. A male patient, *æt.* 43 years, was first admitted to the hospital in 1872, at which time the aneurism was just visible above the sternal notch. An operation was proposed for its relief, but the patient objected. He remained in the hospital about two months (the tumor in the meantime gradually increased in size), and was then discharged at his own request. In 1874 he returned, and it was found that the tumor had increased very much in size. Ligation of the right carotid and subclavian was again proposed, but the patient again refused to be operated upon. He remained in the hospital for a short time, and then went out considerably improved in his general condition. He has occasion-

ally been in the hospital since that time, remaining for a while, and then going out, and in March, 1875, he went out and resumed his occupation as a porter.

Meanwhile the tumor increased in size, the aneurismal sac approached nearer and nearer the surface, until at length nothing but integument intervened between it and the external world. In the latter part of May he again entered the hospital, when an external tumor was found nine inches in circumference at the base, and projecting from the surface of the chest about three inches. The pulsations were so marked that they were plainly visible; the top of the tumor presented a bluish appearance, and it was evident upon close examination that the process of ulceration had already commenced in the integument covering it. Rupture seemed likely to occur at almost any moment. One day the sac ruptured, considerable bloody serum discharged, and the tumor diminished in size somewhat. Suddenly, about a week afterwards, the tumor ruptured, and the blood escaped with the greatest rapidity. The orderly of the ward seized a quantity of lint and pressed it into the blood and applied compresses over it, thus temporarily arresting the hemorrhage. The man, in the meantime, had lost some seven or eight pounds of blood and was in a condition of complete syncope when the house physician, Dr. Glass, arrived. By the exhibition of stimulants, however, he soon rallied. The circulation was now so slow that it was thought possible to remove the temporary dressings, and substitute a dressing which would be a more effectual protection against a recurrence of the hemorrhage. The dressings, accordingly, were carefully removed and a large mass of laminated fibrine found which had evidently been expelled from the cavity of the sac by the sudden gush of blood. New dressings were applied which effectually controlled the hemorrhage, and the patient was in a comparatively comfortable condition. This condition, however, was only temporary, for about ten days subsequently the second rupture occurred and the patient died. Post-mortem revealed the fact that the innominate artery was *unaffected*, but that the aneurism was connected with the aorta. We have therefore another illustration of the difficulty in making a correct diagnosis in certain cases.

ANEURISM OF THE THORACIC AORTA.

The situation of the aneurism was *thought* to be at the junction of the ascending with the transverse portion of the arch. The local signs present were the existence of a tumor projecting from the surface of the chest about an inch, and having a diameter at its base of an inch and a half or two inches, which had an impulse.

This patient has been in the hospital for a long time, and one point of interest in his case just now is the effect apparently produced upon the tumor by the internal use of digitalis.

It has been considerably larger than it is now, and the man has suffered considerable pain, but he is improving markedly, and it is fair to assume in this case that the improvement is due to the remedy administered. For the improvement began as soon as digitalis was administered in doses sufficient to affect the circulation.

COLICA PICTONUM.

The chief point of interest in this case was the rapidity with which the system became poisoned with lead. He had been at work in the Atlantic Lead Works, Brooklyn, only three weeks when the colic was sufficiently severe to oblige him to seek admission to the

hospital. The characteristic line along the margin of the gums was well marked, and he was soon cured by the ordinary treatment, consisting of cathartics and iodide of potassium.

ASTHMA—PERMANENT EMPHYSEMA.

This case was interesting in one or two points, for instance it illustrated the probability of asthma being developed in a person over fifty-four years of age. This is rare. The man was a laborer, had always been healthy, and was suddenly attacked with difficulty of breathing, affecting him chiefly at night, obliging him to get up from bed and lean over the back of a chair and struggle for breath. The attack was accompanied by acute bronchitis. There was no chronic bronchitis, and he is now left with permanent emphysema. He has received great benefit while in the hospital from the use of iodide of potassium, which was administered with reference to the bronchitis.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from June 27th to July 3d, 1875.

BROOKE, J. O., Assistant Surgeon.—Granted leave of absence for one month. S. O. 130, A. G. O., June 30, 1875.

GIBSON, J. R., Assistant Surgeon.—Assigned to duty at Fort Fetterman, Wy. Ter. S. O. 73, Department of the Platte, June 26, 1875.

HUEBARD, V. B., Assistant Surgeon.—Relieved from duty at Jackson Barracks, La., and assigned to duty, temporarily, as Medical Director of the Department. S. O. 120, Department of the Gulf, June 25, 1875.

MIDDLETON, J. V. D., Assistant Surgeon.—Granted leave of absence for one month, with permission to apply for an extension of two months. S. O. 118, Department of Dakota, June 24, 1875.

Medical Items and News.

"MEDICAL REGISTER AND ADVERTISER" is the title of a new quarterly journal, issued in Anna, Ill., under the editorial management of Dr. James I. Hale.

PERSONAL.—Two physicians in Quincy, Ill., have been sued by a patient on whom they operated for hernia. The declaration states that the defendants conducted themselves in an ignorant manner by unnecessarily, wantonly, improperly, and unskilfully performing a surgical operation on the body of the plaintiff, by cutting through the flesh of said plaintiff into the cavity, and through the left lower region of the abdomen, and in an unskilful manner the defendants took and removed from the cavity of the abdomen of plaintiff twenty-five feet of bowels, *by reason of which ignorance his recovery is greatly impeded!*

PHILADELPHIA HOSPITALS.—The University Hospital receives \$10,000 by the will of the late Mr. Towne.

The Jefferson Medical College is said to have bought ground in the rear of their present edifice, on which to erect a hospital that shall communicate directly with the college building.

THE JOURNAL OF PSYCHOLOGICAL MEDICINE AND MEDICAL JURISPRUDENCE has again undergone a change in the resignation of Dr. Hammond and the advent of his successor, Allen McL. Hamilton, who intends to make it quarterly instead of monthly.

THE BOSTON MEDICAL AND SURGICAL JOURNAL of June 17 (Boston: H. O. Houghton & Co.) is filled with matter relating to the early history of our country. There is a copper-plate frontispiece of Dr. Joseph Warren, and extracts are given from his day-book. The Diseases of America: letters written by a Hessian surgeon; A Tory Surgeon's Experiences, June 17, 1775; The Sick and Wounded at Bunker Hill, and a memorial poem to Joseph Warren, by Dr. Oliver Wendell Holmes. We hardly need to say that this number is not only unique in the literature of medical journalism, but also well worthy of preservation by all those who honor the noble example of the elder Warren.

PRIZE ESSAY.—The Medical Association of the State of Alabama has received from Dr. S. D. Seelye one hundred dollars to be offered as a prize for the best essay on "Bright's Disease." Competition is open to the whole country. The successful paper is to be the property of the Association, and will be published in its *Transactions*. Unsuccessful papers will be returned to their authors, and honorable mention will be made of such as are exceptionally good. If none of the essays submitted are deemed worthy of the prize, competition will be open for another year. A medal of the value of the prize will be given if the successful candidate prefers it.

IOWA STATE MEDICAL SOCIETY.—At the meeting of the Iowa State Medical Society, held at Davenport, which closed its session on the 28th ult., the following were elected to be officers for the ensuing year:—*President*, W. F. Peek, of Davenport; *1st Vice-President*, H. Restin, of Cedar Rapids; *2d Vice-President*, Dr. — Osborne; *Recording Secretary*, S. B. Thrall, of Otumwa; *Assistant Secretary*, J. F. Kennedy, of Des Moines; *Treasurer*, J. W. Gustine, of Panora; *Member of Nom. Com. in Amer. Med. Assoc.*, W. Watson.

The Treasurer reported a balance of \$629.40 in his possession. A committee was appointed to prepare and present to the centennial meeting a History of Medicine in Iowa. The publication of the proceedings of the Society, commencing with 1871, was ordered, and the Society adjourned to meet in Des Moines in February next.

SURGEON-GENERAL JOHN FULLERTON BEATSON has been appointed Surgeon-General of the Bengal Army.

SUPERINTENDENT OF HEALTH OF WILMINGTON, N. C.—The Legislature of North Carolina have created the above office, and specified that the duties of the incumbent will be to give medical attendance to the city prisoners, to such out-door poor as the Mayor may direct, and particularly to those with contagious diseases. In case of the outbreak of infectious diseases after a vessel has passed quarantine inspection, he shall have power to return the vessel to quarantine at the mouth of Cape Fear River. He is also to keep on hand good vaccine matter, and to vaccinate the poor of the city. The salary is to be \$100 per month.

FOR INGROWING TOENAIL.—DR. D. S. FISKE, of Brookfield, Mass., writes: "Remove a V-shaped piece of the fleshy part of the toe so as to bring the nail over the outer part of the toe, making a flap of this outer part, and it will make a narrow toe and remove the difficulty better than any operation I have ever tried."

THE IRISH HOSPITAL GAZETTE, which completes its third volume with the June 15th number, is to be hereafter amalgamated with the well-known *Dublin Journal of Medical Science*, which, with its July number, commences its sixtieth volume.

THE INTERNATIONAL CONGRESS OF OPHTHALMOLOGY will meet in New York City on the second Tuesday in September, 1876, at twelve o'clock noon. The following extracts from the rules of the Congress will give an idea of the general character of the Society, and of the terms of membership:

"1. The object of the International Periodic Congress of Ophthalmology is to promote ophthalmological science, and to serve as a centre to those who cultivate it. It will entertain no discussion foreign to this object.

"2. The number of members is unlimited.

"3. Every member must be either a doctor of medicine, or of surgery, or of science, or possess some other equivalent degree, or be distinguished for his scientific knowledge.

"4. Candidates for admission into the Society shall be admitted on presentation of their diploma or of their scientific title, unless ten members demand a ballot.

"5. The sessions of the Society shall take place every fourth year, and be limited to ten days."

"11. The Society gives no diploma. Before the opening of each session a card available for admission to all the meetings, and signed by the President and Secretary, shall be given to each member on payment of his subscription (fixed at \$2), and upon signature of his name on the register of those attending the meeting."

Among the members of this Congress are such men as Arlt and Stellwag, of Vienna; Girard-Teulon, Javal and Wecker, of Paris; Helmholtz, of Berlin; William Bowman, George Critchett, R. Liebreich, J. W. Hulke, and Soelberg Wells, of London; Donders and Snellen, of Utrecht, Holland.

It is hoped that many of them will come to New York in 1876. The committee are making all efforts to secure a large attendance, and one that will leave its mark upon the progress of scientific ophthalmology. The co-operation of the profession of the United States in securing these objects is earnestly desired by the undersigned, the Provisional Committee appointed in London in 1872.

CORNELIUS R. AGNEW, M.D.

HENRY D. NOYES, M.D.

DANIEL B. ST. JOHN ROOSA, M.D.

THE CHANGED ORGANIZATION OF THE BROOKLYN HEALTH BOARD.—The Board of Health, as reorganized by Assemblyman McGroarty's bill, which was signed by the Governor, will consist of three members—the Presidents of the Boards of Aldermen and Police and a physician who has practised for ten years in that city, to be appointed by the Mayor. Dr. Otterson has been appointed as the third member of the Board.

DEATH RATE OF THE LABORING CLASSES.—MR. S. ROYCE, in a recent address before the New York Liberal Club, said that as many persons die every year of consumption among the poor as die of all other diseases among the wealthy. The annual death-rate among the laboring classes is, he said, 55 to every 1,000, while among the wealthy and well-to-do population the death-rate is only 15 in 1,000.

A PECULIAR CASE OF TRAUMATIC EMPHYSEMA.—Pauçin found a considerable swelling of a portion of the thigh, the scrotum, the lumbar region, and the lower part of the abdomen, in a laborer, who said that, in punishment for some supposed injury done to them, two of his companions held him, while a third made a small incision in the inner surface of the pre-

puce, introduced a small tube into it and blew in air. An examination disclosed a small ragged wound three millimetres in length at the point indicated.—*Gaz. des Hôpitaux.*

AN ADVANCE IN DENTAL SURGERY.—Before "The American Academy of Dental Surgery," held on Thursday evening, June 10, 1875, George H. Perine, D.D.S., of New York, made some interesting remarks on the use of the galvano-cautery for oral surgery, which were followed by illustrations.

Dr. Perine claims to be the first person who has applied that particular cautery in dental surgery. He has found no agent so available and so efficacious in certain dental operations as the galvano-cautery, and strongly recommends its use to the profession at large. The battery employed by Dr. Perine is one of great power, and is regulated to suit the operation. The advantages claimed are that it does not affect the body in any degree unpleasantly, because the electric action is absolutely confined to the parts in contact with the blade or broach, the application of which is painless, and so instantaneous that no other known agent can compare with it; the application of it is easy and simple, and free from shock and hemorrhage (a desideratum of great moment), and finally, the separation process is rapid. Dr. Perine not only reasons warmly on this subject, so important, but he believes that the use of this particular cautery in dental surgery will become universal, for the extension of which he cheerfully imparts to his professional brethren his knowledge and experience.

DR. B. A. SEGRU, Sanitary Superintendent, yesterday sent in his resignation to the Board of Health. It was accepted at once. Dr. Creamer and ex-Coroner Jones are candidates for the position.

DR. B. FORDYCE BARKER is to take part in the final discussion on puerperal fever by the London Obstetrical Society on the 7th inst.

DR. HORNER is the medical officer on the *Pandora*, which was to leave England on the 23d ult. for an exploration of the Arctic regions.

MR. J. N. RADCLIFFE has been elected President of the Epidemiological Society.

THE DEUTSCHE KLINIK has suspended publication.

SEXUAL WRONGS.—*The Irish Hospital Gazette* thinks "it is quite time that those who have the education of the male human animal should by some means drive or hammer it into his dense moral consciousness that his procreative power was not given him solely as a means of amusement, and that women have other functions besides ministering to this often morbidly excited appetite."

HOSPITAL SUNDAY.—*The Lancet* of the 19th of June announces that up to the 16th, the amount received at the Mansion House was £9,000, exceeding considerably the amount received by the same time the year previous.

ANTI-VACCINATIONISTS in Keighley, England, are meeting their reward. The Board of Guardians some time since suspended the Vaccination Act in the district. Small-pox now prevails to an alarming extent, seventy cases, of which nineteen proved fatal, occurring in the town and neighborhood in one month.

VACCINATION AMONG THE POOR OF THIS CITY.—During the month of July the Board of Health will furnish, on application at 301 Mott St., vaccine gratuitously to physicians who vaccinate without pay.

Original Communications.

BIOMETRY: ITS RELATION TO THE PRACTICE OF MEDICINE.

By MOREAU MORRIS, M.D.,

NEW YORK.

[A Paper read before the Section on Practical Medicine of the American Medical Association, at its Annual Session, held in Louisville, Ky., May, 1875, and referred to the Committee for Publication in the Transactions.]

In the practice of medicine and surgery the arts of diagnosis and prognosis are of the greatest practical value. To excel in these arts, much study and great experience are usually required.

The initial step in the treatment of disease or injury is first the diagnosis, second the prognosis. Any art or knowledge that can aid in acquiring proficiency in this direction may be considered as an additional contribution to the science and art of practical medicine.

Without a sufficient preliminary knowledge, it would only be empiricism to undertake to treat scientifically any malady.

To be able to make an accurate diagnosis properly, the first and most important requisite is to study the individual characteristics of the person as well as the symptomatology of the disease.

Symptoms vary with the same disease in different individuals, hence a study of symptoms alone is only an imperfect method. Theoretical knowledge may be of value to the purely scientific student, but practical knowledge is absolutely necessary to the successful medical man. The recent graduate in medicine leaves his alma mater comparatively unlearned in the art of diagnosis; his first efforts are nearly guess-work. He no longer receives from his tutors hints and suggestions, and must perforce launch upon the sea of uncertainty and doubt, and perhaps with his very first case discover that he has made a great error.

If he has had practical bedside experience, and been taught by a competent instructor, his first diagnosis may not be at fault, but if he has had no such practical advantage, then indeed it were fortunate for the patient to be possessed in no small degree with great viability. But the study of symptomatology alone can never perfect one in diagnosis and prognosis. There needs something more than present symptoms upon which to base a correct understanding of any case,—a knowledge of the physical indications of longevity must enter largely into these elements.

If symptomatology could illustrate for prognosis that degree of certainty which it does for diagnosis, the practice of medicine would be less empirical and more reliable.

From the earliest history of medicine there has always been recognized an indefinable something inherent in the human system, varying in degree and force; this has been variously designated the "tenacity of life," the "tolerance of disease," the "natural vigor of constitution," the "vis medicatrix nature,"—by which some individuals seem to be able to endure and pass successfully through the most serious of maladies or the most severe injuries without succumbing. Many instances might be enumerated in illustration, but every practitioner will readily recognize such examples in his own experience. How often persons have recovered after injuries, gunshot wounds and exhaustive diseases, who at the time, to all human foresight, seemed beyond recovery.

There is some inherent principle which mysteriously

sustains life through these severe onslaughts. We must recognize a "vis preservatrix" and a "vis tergo." What this force consists of, neither anatomy, physiology, pathology, microscopy, nor chemistry has been able to elucidate. We know that man inherits vital properties which are in force from conception to death; that his various components are endowed with lifetimes of variable duration; that, like other living things, some parts decay and perish before others, in regular succession. One day we see the plants beneath our feet spring up, throw out their green leaves, and budding flowers, all endowed apparently with vigorous, blooming life; and in a few months, or perhaps days, their flowers, leaves, and stalks fade, wither, and die. These are but prototypes of man. He springs up, flourishes for a time in full vigor, and one by one his discerning organs fail, until at last his physical entity ceases. The vital property has ceased to carry on its secretive power in one organ after another, until it can no longer sustain life. It is not within human ken to describe this vital property.

God breathed into our bodies life, which proceeds under the various laws of our being, so long as they are not violated, until the human machine wears out. It is within our power to cut it short, but not to prolong it beyond its natural inheritance. We can study its processes, observe the laws which govern it, judge of its force approximately, see its manifestations, and estimate its probable period. There are certain *uniform indications* by which we may judge of man's *probable lifetime*. Some are *endowed* with short life, some with a probable long and healthy life.

Inherited tendencies, habits of living, occupations, observance of sanitary law and residence—all have their direct bearings upon the question of longevity. Acute diseases, accidents, etc., have their life-shortening influences. All of these must be studied in their various relations to length of life.

This study has now resolved itself into a special science, and has been happily designated by the name of

BIOMETRY.*

Its adaptation to the practice of medicine is only one of the many applications of which it is capable.

Its study is comparatively of but recent date. Like every other science its study involves labor and care; statistics are to be collected and compared, its rules and laws elucidated and fixed, to make its practical application of value. When these laws become understood, their application is readily recognized. In medicine, in life insurance, in business, in social life, in a higher elevation of mankind generally, both physically and morally, the application of the science of biometry will be found invaluable. The laws of natural selection, by which physical perfection may be attained, will find in its exposition the true guide-posts by which to accomplish that much-desired result. Intuitively we all apply its principles, even without, perhaps, being able to analyze the reasons for our judgment. The physician, by observation and long force of habit, is constantly applying its fundamental truths. He sees nature asserting and exhibiting wonderful endurance and adaptation under the most adverse circumstances, yet he is unable to define or explain the reasons.

In every-day life we constantly apply its principles in our intuitive estimation of our fellows, we judge of

* "This is a word whose precise derivation illustrates its intended meaning—from the Greek words *bios*, life; *metron*, a measure." And as "Geometry, from *Ge*, the earth, and *metron*, a measure, means not merely a measure of the earth, but also the science and art of measuring the earth, so does biometry mean the science and art of measuring life or lifetime."

men's qualities or adaptation for certain kinds of business without system or explainable method.

To Dr. T. S. Lambert, more than any other man, belongs the credit of having studied and reduced to a scientific basis the development and application of this instructive and interesting science. During many years of close application and observation he has fortified its truth by thousands of examples, and so simplified its practical application to the business of life insurance, that its laws have become the fixed data in estimating the probabilities of life's period; and as this business, when scientifically and successfully transacted, very largely depends upon a correct estimate and judgment of the probable length of any proposed life, as a matter of security and equity, its application in this direction has already, in the company with which he is connected, reduced the hazard of the business to one of great certainty.*

He remarks in speaking of a lifetime:

"It includes inception, birth, and the intervening period until death. Life is never found in any other than these relations.

"It is seen under these different forms in the plant, in the animal, and in the egg. We should expect to see in each of these forms some substance in common, in which the life inheres; and if only one substance is common to all these, life must be dependent upon that.

"A plant is constituted of woody tissue and of secretory tissue; the egg, of an amorphous substance and secretory tissue; the animal, of several tissues and of secretory tissue.

"The deduction is evident, secretory tissue is the only substance common to all living things.

"It has also a lifetime; it is born, it dies. No other substance is like it in these respects. In fact, life exists only in connection with secretory tissue, and when one ceases to exist the other does also, and it is said that death occurs. While secretory tissue acts, life is exhibited; as soon as its action ceases, life is shown no longer; life must therefore be the property of secretory tissue, and its duration must be fundamentally dependent upon their constitution; or lifetime is merely the period during which the secretory tissue can act under ancestral influences, and when from any cause they lose that force, death occurs.

"Secretory tissue has, therefore, a birth, or a departure from ancestors, which is necessarily related to its decadence, on account of its gradual and irreparable exhaustion of ancestral influences.

"Secretory tissue is the only kind of tissue or substance that is transmitted from ancestors in either plants or animals, and therefore can, and does, contain in itself all the inherited ancestral influences that are transmitted.

"Different natural lifetimes of different plants and animals must, therefore, be owing to natural or constitutional differences in their secretory tissues, and the necessary antecedent conditions for producing these differences must be found in the antecedent ancestors.

"There are not only different kinds of secretory tissue, having different lifetimes, in the same plant, but different portions of the *same* kind of secretory tissue in the *same* plant have different lifetimes. This is also certainly the case in animals.

* The former method of basing the cost upon the general average death-rate of all mankind, as deduced from various experience tables, has, in that company at least, been discarded, and the results already accomplished by the application of this science to the problem has created the greatest astonishment in the life insurance world. Death ratios, from having been ten to twelve per thousand among selected lives, are reduced by this method with almost absolute certainty to less than four per thousand; hence the direct pecuniary benefit to the world, as respects life insurance, is more than three-fold as regards the proper cost to such risks.

"In man there are fourteen kinds of secretory tissue, secreting or producing, in their peculiar manner, from the blood, as many kinds of fluid. For example, the tear fluid, saliva, gastric juice, the bile, pancreatic, urinary, etc. In every kind of organ one or more kinds of the secretory tissue may be found. It may be also said that the six solids of the body are secreted, and the remark would in a sense be true. It may also be said that these, *i.e.*, the bony, gristly, sinewy, nervous, and muscular, as well as the secretory proper, do not only secrete, but exhibit life—for *secretion is living*, and cessation of the power or property of secretion is death. But in a different sense the secretory tissue performs this function of secretion, for it not only secretes itself, as the other five tissues do, but it also secretes some fluid for other uses than are found in itself alone,—the other tissues do not. In the new-laid egg neither of the other five tissues are found, but secretory tissue is there; ere long the others appear. Each of these can be produced without the antecedent presence of any tissue of its own kind, but secretory tissue never, so far as we know, except in the presence of, and in contact with, secretory tissue.

"What hinders us, then, from finding all the organs endowed with peculiar lifetimes, dependent upon the lifetime of the secretory tissue or tissues essential to the structure of the organs respectively?

"It will also be found that all of the secretory tissue in any organ do not necessarily have the same lifetime. *Example.*—In the sides or walls of the stomach, we find, opening into that organ, millions of microscopic tubes, each one distinct from the rest, its interior constructed of secretory tissue necessarily endowed with its special lifetime, which may be shortened, but cannot be lengthened. It would be truly wonderful if the lifetime of all the tubes should be the same. Suppose 100,000 tubes to be endowed with a lifetime of forty years, and the rest able to live to seventy or upwards. Would the person pass the age of forty without inconvenience? The digestion would certainly be impaired, at least for a time, and doubtless he would always after be incapable of digesting as much as previously. Although he might feel and appear to be as well, yet he could not accomplish as much of some kinds of work as if he had 100,000 more gastric tubes.

"In the stomachs of persons past the middle of life, exposed by post-mortem examinations, it will usually be found that already a larger or smaller number of the gastric tubes have been obliterated; the organ had, therefore, so much less capability of digestion. If we examine these tubes, we find that at the bottom of each the secretory tissue appears in the form of cells or minute oval bags, which are filled with the gastric juice—that in fact is secreted in them. These cells grow with almost inconceivable rapidity when the gastric juice is needed in the stomach, and, loosened from their birthplace, they come up to the mouth of the tubes and, bursting, yield their contents to aid in the process of digestion. Successive cells pass up from the same origin in the bottom of the tubes. In this general form of cells, of different shapes and properties, the active secretory tissue everywhere appears. Each cell has a very short lifetime, and each cell series has its own lifetime. The being born and dying of the cells is continuous, but in each succeeding cell there is a change and a progress, so small with each step, that it is not appreciable with our present means, but so sure and steady, that in a certain period the process will necessarily conclude; life will then be no more manifested by that cell series,—its death will be said to occur, and its position will be barren.

"Organs, then, are not units in regard to the secretory tissues that enter into their construction. Each organ is an aggregation or a compound, and in the units, as they may be called, of the organs, there may be, and often is, a great diversity of natural lifetimes, apart from any effect produced by contingent influences. These produce what may properly be called *disease, i.e.,* that which cuts short, or tends to cut short, a natural lifetime. But when the death results from the extinction of the natural lifetime of an organ, or a part of it, at its full period, it will also be called disease, if the other organs have a longer natural lifetime and appear to be enduring. But if all of them have reached their natural period of death and manifest completed life, the person will be said to die of *old age*. But there is more frequently old age of an organ, or of part of one alone, than of all of them at once. If a sufficient portion of the secretory tissue of an essential organ be short-lived, a person will die at *its* death, no matter how long-lived the other organs may be. But if the short-lived organ is not essential to general life, the use of it only is lost. A person may inherit from a father deafness (early death of the ear), or from the mother blindness (early death of the eye), yet live to a good old age; but if he has inherited lungs, kidneys, stomach, or liver short-lived throughout, he dies of the so-called disease—properly speaking, of old age—of organs to which his death is attributed.

"But they are the resultants of the co-ordinated vitalities and longevities of his organs, which, superficial or deep-seated, directly and indirectly, indicate their respective life capacities to the skilled or expert observer. Hence the difference in the vitality and longevity of men depends, primarily, upon their organic, or rather, tissural constitutions, and upon the relative importance of the shortest-lived organ or part of it in the organism.

"The inherited lifetime is always the resultant of the conjunction of antecedent ancestral influences, either of which, or both together, may deprave the inheritance below that of either parent stock. This is often the case, while very seldom do the concurrent influences produce a better condition than any antecedent. To the ancestry we must look for the capability of long-living. It is observable that a nose may resemble that of one parent, and an ear that of another; the hair may be as red as a grandmother's on the mother's side, and the beard as dark as that of the grandfather on the father's side. The length of the nose may be like the mother's, the breadth like the father's—a single organ showing perhaps half a dozen inheritances, why not half a dozen lifetimes? Why not inherit a stomach from one, a liver from another, or a single such organ from a half-dozen ancestors? One brother, externally, almost entirely resembles the mother; a sister resembles the father so closely that many would say she does not resemble the mother at all. Why may it not be so within, as well as without? It is. It is a fact that a large majority of persons die nearly at the same age as some ancestor or perhaps younger, and of the same class of diseases. There is usually, also, a strong external resemblance. A great-grandfather died of heart disease at 76, a grandfather at 71, a father at 65; the son strongly resembles the father and grandfather; the son rightly infers that 'he will die still younger of the same disease;' but instead of calling his case a disease, he should say that his natural lifetime will doubtless be shorter than his father's.

"All parts of the body are originally constructed, and are each moment kept in repair, by the same dom-

inating nervous centres. Those which make the stomach what it is, will produce some other effects which can be seen externally. Each organ exerts an influence, greater or less, directly or indirectly, upon all the other organs—upon those at the surface as well as upon those within. 'Like causes produce like effects,' *within* the body as well as out of it. When, therefore, effects are seen upon the surface, the causes may be known to be also acting within.

"Can the internal inheritances, or the constitutional lifetimes of organs, be discerned by external marks, appearances, or indications? Certainly, in most cases.

"In the first place, by studying the necessary physiological relations of the organs of the body and the influences which they exert upon each other; and in the second place, by observing the external manifestations of the body with a discerning eye, the external indications of internal conditions and of the constitutional lifetimes of organs can soon be practically learned.

"*Example.*—It will be found that the kidneys, for good physiological reasons, have intimate relations with the skin, and that their conditions, liabilities, and probable lifetimes are discerned more readily, in fact through corresponding peculiarities of the skin, than they could be by looking directly into them, which cannot be done during life.

"Almost every one is familiar with various facial expressions or constitutional peculiarities that indicate present or future health of the various organs. To see more only requires a closer observation, especially if guided by the light of a preparatory study of physiological relations."

The laws of biometry are abundantly illustrated by heredity. The histological characteristics of persons when studied under these laws present the most convincing proofs of the status of biometry as a true science. In the examination of the ancestral histories of thousands of individuals, the deductions therefrom establish the fact that certain measurements can be relied upon almost infallibly, by which to read backward from the person the life characteristics of the ancestry, and hence inversely to determine the individual's life probabilities. So, when we find a person presenting these general measures in due proportion, we may judge, almost invariably, of his powers of resistance or natural viability. If so be he is descended from a healthy, long-lived stock of both parents, almost without exception it will be found as a rule that he is both healthy and long-lived, able to endure much hardship, resist grave maladies, and to recover from the most serious injuries and great nervous shocks.

Again, it is found from observation that where there has been long and vigorous ancestral stock upon one side, with perhaps short life engrafted from the other, such person will arrive at a period of partial decline, with ill-health, and subsequently recover, living on and beyond this deflection, being sustained by the vitalizing secretory influences of the longer-lived ancestor. A moment's reflection will call to mind many such instances, as when persons have remarked that at a certain period of their lives they were suffering from some special disorder, from which after a period they have seemingly entirely recovered and enjoyed sound robust health. Many such instances must have occurred in every medical man's practice.

That longevity is a resultant of heredity no one will dispute, and that it does not depend upon race, climate, mode of life, or special observance of sanitary law, is also a self-evident fact. Those who have inherited it can, seemingly with impunity, almost defy all sanitary law, and yet continue to live up to and beyond the allotted limit of "threescore years and ten,"

while those who have not inherited long life cannot by any system of life, or observance of the laws of health or process of prolongation, protract their naturally short-lived inheritance. Of course we must admit that abuse can and does shorten the lives of the naturally long-lived, and acute disease or great injuries cuts them off suddenly; but the rule holds good that the naturally long-lived inheritance affords that innate power of resistance which will carry them through disaster and disease that will certainly destroy the naturally short-lived.

The probably short-lived may be equally healthy and robust, and able to endure almost as much, while that life lasts, as the longer-lived, yet it seems to be the fact and nature's law, that the period of existence has had its set limit, beyond which no process of prolonging can avail to carry it further than the allotted period. The discerning elements of the vital organs have their limits, and hence control the existence of the whole organism. We see this illustrated in almost every organ of the body; certain parts cease to perform their functions, die out; and, so long as these are not vital, life continues, although it may be in a restricted sense,—as, for instance, persons become bald or partially so at a certain age; they say the same occurred in their ancestors at about the same age; others find their digestive powers failing, and remark the same thing as having occurred in their parents or grandparents. The secretory vitality of these parts is then seen to follow the law of heredity.

Without an inheritance of long-lived secretory powers, it is vain to expect any great degree of longevity in the descendants.

In estimating the probability of a lifetime it is entirely useless to depend upon the general average of human life. This rule holds good only as respects human life at large, and therefore we must look beyond life statistics to sum up the problem. *With the duration of individual life general average holds no command.* Ancestral longevity will not obey the general average law, but defies death in many shapes, holding on tenaciously until the machine, actually from rust and the interstitial deposits of years among its most delicate parts, wears out. Even though many times wrecked, battered, shorn of all their sails, and rudderless, their sound-timbered, well-built organs ride out the storms of life to an extreme old age.

The important question then arises: Are there any well-marked indications, externally manifested, by which it is possible to judge of men's powers of resistance to the destructive influences of life?

Are these indications so palpable that ordinary persons can judge by the personal characteristics sufficient to estimate the probable chances of recovery, or in other words of the probabilities of life in disease in different individuals.

These questions may be answered with confidence in the affirmative.

If such is the fact, then it must be admitted we have at hand one of the most certain means of deciding upon the prognosis, and the science of biometry comes in as the grand marshal of symptomatology and diagnosis. Our treatment of disease can be regulated accordingly. It will not be necessary to fill the human stomach with the contents of the apothecary shop in order to find "something that may hit the disease." By reason of the certainty of our knowledge we can inspire our patient with the hope that is within us, and when he is so inspired, half the battle is already won. Who has not seen the brightening eye, the stimulated courage, the grand fight of an unconquerable will, which hopefully and patiently has resisted the almost

overpowering death struggle, when his doctor, judging from his own intuitive perception of the great tenacity of the life before him, has assured his suffering patient that he will recover?

Does it not occur to every practitioner, how many times in his own practice the thought has instinctively forced the conviction upon him that the patient would recover, and again with another patient his hope has sunk from seeing that there was no sustaining vitality to aid in the desired recovery?

True, some medical men take no note of such conditions; they hope and fear for all equally and without special discernment.

But most physicians will recall scores of instances in which they have been favorably and unfavorably impressed by different patients, and mentally, at least, prognosed their cases accordingly.

Indeed, so decided and correct is this judgment with some physicians, that they and their acquaintances are prone to consider their off-hand conclusions at the bedside as almost, if not quite, intuitions.

Let us pause for a moment and reflect upon these facts. Is it not a little singular that they have not more strongly and distinctly arrested our attention and so fastened themselves in our minds that we should draw from them the instruction which they are capable of yielding?

When we ask ourselves or others why these impressions, of decease of one patient and recovery in regard to another, how indefinite and unsatisfactory the answer! Ought we not be able to give a reason for the faith that is within us? Are not our impressions wholly dependent upon the appearance of each patient respectively? Cannot these appearances be defined, be described in detail completely?

Cannot these appearances be analyzed, and the relation of each detail to disease or recovery be made so clear and conspicuous that even the tyro in medicine may have a reliable guide to a correct prognosis in every case? Shall we say, as is often said, that there is an indefinable something in the appearance of the patient that impresses us thus or so, we know not how or why?

Too long has this mysticism been allowed to govern the medical profession. Too long have we looked upon patients as through a glass darkly, and have envied the select few who seemed to have a mysterious, instinctive insight into the prognosis, as if gifted beyond their more plodding fellows, the mode of which was not to be described by them nor learned by observing their methods.

These croneous notions must be laid aside, and we must see to it that prognosis is to be acquired in a scientific manner, not alone simply by feeling the pulse, looking at the tongue, taking the temperature, or other similar means, but by a thorough detailed analytical observation of all the signs and indications that patients present in the size and color of some or all parts of their bodies.

Another very important part of our prognosis will be dependent upon our having a correct idea upon the following point; that our organs are not units but communities, each member or element of which is nearly, if not quite, independent of its neighbor; for example, each gastric tube or gland in the stomach is, or may be, an independent unit, so far as its longevity and liability to disease is concerned.

Virehow has well said that a single cell may be independently diseased.

Dr. Lucas, in his *Traité Physiologique et Philosophique de l'Hérédité Naturelle*, remarks as follows: "The average of life plainly depends on locality, hy-

giene, and civilization; but the *individual longevity* is entirely exempt from these conditions."

"Everything tends to show that long life is the result of an internal principle of vitality which privileged individuals receive at their birth. It is so deeply imprinted in their nature as to *make itself apparent in every part of their organization.*"*

The foregoing statement of Dr. Lucas is also quoted with emphatic approval in a recent work on Heredity, by Ribot, of whom Dr. Lambert remarks that he "may be justly regarded as the ablest of European writers upon this subject."

This interesting and practically important idea of the different lengths of life is well illustrated in the hair glands on different heads not only, but on the same head. Some hair glands inherit a life of ninety years, while their fellows terminate their inherited longevity at twenty years or under.

As before remarked, how often we see baldness follow ancestry, even in quantity and position, and the question cannot be avoided: Does not analogy legitimately argue that a similar condition should be expected in every other organ of the body possessing a community of glands?

It is not enough that we analyze the appearance of patients, so that we can discern which *organs* are affected, but we should be able to recognize to what *extent* they are impaired, how large a *portion* of them has reached the natural terminus of the longevity belonging thereto, and which is bound to die then and there. If this portion is large enough and belongs to a sufficiently vital organ, to commit homicide upon the other organs of the body depending for life upon the dying portions, it matters not how long-lived the other portions or the other organs may be by inheritance, they must then and there die from inanition. Marasmus is an apt illustration of a homicidal death by this method.

In such cases there will be at first a general appearance of much vigor, and a man of but little observation would be likely to prognosticate recovery, not remembering that "the chain is never stronger than its weakest link." We must observe the weak spots. Then shall we find that many more deaths are produced by natural unavoidable causes, namely, the termination of the inherited naturally short life of some organ or portions of it indispensable to the continuance of the whole, than we usually have supposed; whilst again many recover from severe attacks on account of the inherent longevity of such a proportional part of the diseased organ that there really was no danger of dying even under the worst kind of treatment.

Will not these suggestions account for the apparent success of all kinds of quacks and ignorant pretenders everywhere and in all times?

Will not the consideration of these two fundamental ideas of biometry—first, that each organ is not a unit but a community of parts in regard to longevity and liability to death; and second, that the inherent longevity of any considerable part of the body can be discerned through the signs and indications that its various external parts manifest—will not, I repeat, these points of biometry make the prognosis of disease much more interesting and satisfactory and practical in its treatment than has ever been the case? Will it not be gratifying to exchange the unsatisfactory impressions, intuitions, or guess-work, as some are inclined to call it, for a rational, reliable method governed by fixed law?

All who have carefully watched the progress of disease must have been convinced that there is some general law to which these instinctive intuitions of many physicians point.

That fundamental law is found only in or rather constitutes the science of biometry. Not only do all beings endowed with life tend, in obedience to the law of heredity, to repeat themselves in their descendants, but also in their physiological and pathological characteristics as related to health and disease, follow the same laws, or rather the broader one, of which the signs and indications of longevity are the expression.

But how may we discover the indications by which to judge in any given case of the probable lifetime naturally belonging to it?

By instituting comparisons or observing certain general configurations uniformly found in a very large number of individuals, it has been found that certain universal conditions pertain to the long-lived and to the short-lived exclusively. These are found in the size, shape, proportion, color, and capacity of all parts of the body.

Thus we can compare persons descended from long-lived with those from short-lived ancestors, and notice the differences which, as a practical fact, are *found to be well defined*; for example, the following: the comparative size and shape of the head; the colors of its external components, as hair, beard, eyebrows, eyes, shape and size of nose, lips, chin, and features in general, and their comparative relative measures; the trunk with its relative proportions,—it may be here remarked, that the *length* has even a more important significance than the circumference; for when the proportion of the trunk is in excess of one-third the height of the figure, we may be assured of corresponding great life, tenacity, and capacity. A comparatively long trunk gives us a form that affords room for the functions of respiration and digestion, the two most important life-sustaining functions of the whole organism.

Given good respiratory capacity and good digestory apparatus, may we not prognose a healthy, vigorous constitution?

In looking over these indicative points, especially in the sick man before us, we need also to inquire into his ancestral characteristics. What has been, not the average, but the special duration of the antecedent lives of his progenitors? What were their peculiar diseases, family diseases so called, and of what diseases, and at what ages did they die, if dead?

Here lies the clue to the factors of the disease under observation in any case.

By observing and applying the laws of biometry in the treatment of disease, the medical man places himself in the front rank of the benefactors of mankind, and he is also thereby enabled the better to apply the great laws of hygiene for the benefit of his patrons. Observing the temperament, the tendencies to some special form of disease, the predispositions, he is qualified to extend his warning advice regarding occupation, residence, and habits of life, and to suggest at what period of life may be expected certain ailments, and the necessary precautions to avoid, if possible, their worst effects.

Thus in applying the laws of biometry we may not only be useful to our fellow-man in curing disease, but also as conservators by our forewarnings.

We arrive, then, at this grand conclusion, that when we come to study the laws of biometry, we are no longer at a loss to understand the fundamental reasons of these apparent intuitions; they need only to

* The Italics are ours.

be analyzed to give us the true indices of the viability and power of recuperative energy inherent in our patient. Mysticism is replaced by true science, which, when earnestly studied, gives us the grand truths of biometry sustained at every point by heredity, physiology, pathology, and actual results.

Having exceeded the allotted time which has been already extended beyond the limits usually accorded to papers, I will omit reading the details of the signs and indications, which have been found to be so uniform in their general features as to be reliable indices of longevity (both long and short), and hence useful as indications having relation to the prognosis and diagnosis of disease.*

PENETRATING PISTOL-SHOT WOUND OF ABDOMEN—PASSAGE OF THE BULLET PER RECTUM ON THE FOURTH DAY, FOLLOWED BY RAPID RECOVERY.

By WILLIAM O'MEAGHER, M.D.,

NEW YORK.

ABOUT 4 P.M., on the 25th of April, 1875, an able-bodied laborer, while standing at the bar of a liquor store, drinking with some acquaintances, received a pistol-shot from the hand of one of them. He was at first unconscious of his condition, owing to deep potations, until one of the party, more sober than the others, had made a hurried examination. He was then carried to his home near by, where I saw him shortly afterwards lying on his back in bed, somewhat sobered, complaining of pain, faintness and chill, and restlessly moving from side to side.

A brief thorough examination disclosed the usual appearance of a bullet wound of small size, from which there had been only a few drops of blood externally; how much internally was for future determination; it was also evident that the bullet had penetrated and lodged in the abdominal cavity, having entered at the right upper angle of the umbilical region, the situation of the wound corresponding, as nearly as can be ascertained, with a portion of the transverse colon, the commencement of the duodenum, possibly the greater curvature of the stomach, distended by a hearty meal and fermented liquor. Although the pistol was fired within a few inches of the body, the bullet failed to pass through, owing to the obstacles presented by a coarse cotton blouse, a thick padded vest, four folds of a heavy blue flannel shirt, and a cotton wool undershirt. Without any unnecessary delay in vain efforts to find the bullet, the wound was cleansed, and closed by a compress of old linen, wet with cold water, covered with oiled silk, and kept in place by a broad bandage, tightly applied. During the examination and dressing he vomited freely about a quart of partly digested food and beer, in which, after careful examination, neither blood nor bullet could be detected. An opiate, combined with an alkaline diaphoretic, was freely administered, and ice, with carbonated water, allowed in small quantities, to allay thirst. Directions were given to examine the excretions closely, and absolute rest on the back, with the knees in the flexed position, enjoined.

That night he was tolerably comfortable, vomiting a

little at intervals, somewhat feverish, and unable to sleep. Next day symptoms of peritonitis set in, with a chill, followed by increased pain and tenderness of the abdomen, and a little later by tympanites, so that I was obliged to loose the bandage and apply a bag of pounded ice to the wound. Five grains of Dover's powder, with a grain of calomel, were then administered every three hours. Under this treatment he was more comfortable that night, sleeping a little at intervals, and feeling better next day, the fever having abated somewhat, and the gastric disturbance having subsided into a kind of abortive hicough. The iced bag was replaced by a wet napkin, covered with oiled silk.

On the third day, feeling much better, he expressed a desire to evacuate the bowels, observing that he thought he would be helped by the operation. After some hesitation I resolved to give him an oleo-terebinth. enema, which acted promptly in two free evacuations, followed by speedy relief of all the symptoms—pain, tympanitis, gastric irritation, etc. A careful examination of the passages discovered nothing unusual to prolonged constipation, and I began to hope the intestines had escaped injury. On the fourth day he was much better, but still expressed a desire to go to stool, notwithstanding the free use of opiates, taken as at first prescribed, with very little drink, and no nourishment. After some deliberation I prescribed a castor-oil draught, which operated in the usual way, producing three passages, in the last of which the bullet was found imbedded in a small mass of feces, requiring considerable washing to remove. After this his progress to complete recovery was uninterrupted by any untoward symptom, care being taken only to confine him to light nourishment. In nine days the wound was entirely healed, a little circumscribed induration alone remaining around the scar. He was kept in bed for two weeks altogether, as a precaution. The bullet was part of a patent cartridge, made to fit a Smith & Wesson revolver, size number one, and weighed only forty grains, apothecaries' weight.

I have seen him occasionally since, and, although unable to labor at hard work, he says he feels well and strong, suffering no inconvenience except from an occasional twinge in the site of the wound, and from the bandage which he still wears.

The favorable termination of the case, I think, was owing to the smallness of the missile; to the early closure of the wound; to the entire absence of attempts to find the bullet by probing, a species of surgery not only meddling, but criminally dangerous; to abstinence from food and drink except in small quantities; to absolute rest and a good constitution.

A few similar cases only are recorded, as far as my reading extends—two by Hennen and one by McLeod.

137 E. 117TH STREET, June 23, 1875.

CHARITABLE WORK OF THE CHILDREN'S AID SOCIETY.—For several years past the Children's Aid Society has endeavored to stem the tide of infant mortality during the summer months, and it will be gratifying to know that the Society has decided to open the "Sick Children's Relief Fund" again this year. Parents who are unable to procure proper medical attendance, medicine, and nourishing food for their sick little ones, can obtain them gratuitously by applying at the head-quarters, No. 325 Rivington street, or at the central office of the Children's Aid Society, No. 19 East Fourth street.

* In another edition the signs and indications of biometry will be treated of in full. Please send for the complete edition, to MOREAU MORRIS, M.D., American Popular Life Insurance Co., 419 and 421 Broadway, New York City.

Progress of Medical Science.

A NOVEL METHOD OF TREATING THE VOMITING OF PREGNANCY.—Dr. Edward Copeman, President of the British Medical Association, in an article in the *British Medical Journal* of May 15, 1875, relates the histories of three cases in which vomiting had resisted all the usual remedies, and in which a new treatment, discovered by accident, as it were, succeeded in checking the vomiting almost immediately. In the first case, that of a lady six months advanced in pregnancy, the vomiting had become so excessive as to occasion great fears for her safety. Dr. Copeman saw her in consultation with two other practitioners, and advised bringing on premature labor, which the others at first were rather unwilling to agree to on account of her depressed condition, though they finally acquiesced in the plan advised. Accordingly he at once dilated the os uteri as much as he could with the finger, so that he could feel the membranes and head of the child. An attempt was made to rupture the membranes, but failed, owing to their flaccid condition and the slight resistance offered by the head to an ordinary female telescopic catheter, the only instrument at hand. After this failure it was decided to wait a little while before resorting to other means. In an hour she was seen again, and he was surprised to learn that a longer period than before had elapsed without sickness, so it was determined to wait another hour in the hope of giving her some nourishment. During that time no vomiting occurred, and it was decided to resort to no further active measures, but to wait for further developments. No recurrence of the vomiting took place during the night, and the case went on favorably to full term, when she was delivered of a healthy child, and made a good recovery.

The second case was one in which pregnancy was only of two months' standing, and in which the surgeon in attendance had exhausted the best acknowledged remedies, and had arrived at the conclusion that artificial delivery would be necessary to save her life. Dr. C., keeping the first case in his mind, and wondering whether the dilatation of the os in this first case, by removing any undue tension productive of sympathetic irritation of the stomach, had been the cause of relieving the vomiting, examined the uterus, found some degree of anteversion and the os patent enough to admit the tip of the finger. He immediately dilated the os as much as he could, passing his finger all round, and removing all puckering of the os and rendering its edge smooth. She vomited slightly only once after this procedure, and he left her with the understanding that in case the sickness returned he should be summoned again to bring on abortion. But the summons never came, and in a fortnight he heard that she began to improve decidedly an hour or two after he left, and that the sickness had entirely ceased. Several times since he has heard that she was doing remarkably well, and he believed that she expected to be confined during the month (May).

In the third case, the patient was the mother of nine children. Generally during early pregnancy, and sometimes for several months together, she had been troubled with vomiting, but in this pregnancy, for three weeks before his visit, the sickness had been almost constant. She could retain nothing on her stomach, and was in a very weak and enfeebled condition. Considerable albumen, some pus, and a few casts were found in the urine. There was no dropsy.

On examining the os, he found it patent, puckered, and dilatable, so he proceeded to dilate it as much as possible with the finger, in the hope that the sickness might be relieved as in the other cases. A few days after this he was informed that no return of sickness had happened since his visit, and that she was able to take food without inconvenience, though she was still very weak and ill. Since then he has learned that she had been safely delivered and was doing well.

In conclusion, he says that the subject seems to him to be of so much importance that he reports these cases without waiting for others, or attempting to explain the *modus operandi* of the treatment, but hopes to communicate further when he has more thoroughly thought over the subject, and promises to report any future success or failure that may come under his observation.

Dr. Graily Hewitt, in the same journal for May 29, 1875, gives what he considers to be the true solution of the *modus operandi* of treatment in Dr. Copeman's cases. He says that in 1871 he read a paper (see *Transactions of the Obstetrical Society*, vol. xiii.) in which he enunciated the theory, supported by facts and observations, that vomiting in pregnancy was due to flexion of the uterus, the compression of the tissues at the seat of flexion being the irritation giving rise to the vomiting.

He believes that in all of Dr. Copeman's cases there was acute flexion, and that the dilatation of the cervix relieved the vomiting by overcoming the cramped and confined condition of the uterus; and he believes that this same condition is the cause of vomiting even up to the eighth month, because in such cases the tissues of the uterus at the point of flexion are sometimes left in the early months in a diseased state, being stiffened and unduly resistant, and thus the irritation is kept up. He says that he has been in the habit of treating obstinate vomiting in pregnancy by elevating the body of the uterus, and has found that the same good results have followed as in Dr. Copeman's method.—*British Medical Journal*, May 15 and 29, 1875.

SUPPURATIVE INFLAMMATION OF THE KNEE-JOINT TREATED BY ASPIRATION AND COLD.—RECOVERY WITHOUT STIFFENING.—A man aged twenty, suffering from acute inflammation of the left knee-joint, following a severe sprain, was admitted to the London Hospital, under the care of Mr. Hutchinso. Sixteen days after admission, the joint, in spite of treatment, had become distended with fluid, and the skin was thin and red, showing a tendency to point. The pulse was rapid and the temperature rose to 103°. Mr. H. says that the condition of things would have fully justified incision into the joint, but that he preferred at first to try the aspirator. The needle was introduced at the most prominent point of the swelling, and about an ounce of distinctly purulent synovia, opaque and yellow, was withdrawn, when the canula became blocked. The instrument was then removed, the joint still containing a good deal of fluid. On the following day, November 17th, the largest trocar of the aspirator was introduced, and about two and a half ounces of purulent fluid were withdrawn. By the evening of the following day he was much relieved, and a couple of ice-bags were placed on the joint, the leg still being kept upon a splint. No tension or tenderness was discovered, and no fluid accumulated after this date. Three weeks after the tapping, the splint was removed and he was allowed to bend his knee in bed, which he could do freely and easily, nor was it followed by any bad consequences. By January 15th he was quite well, with no swelling about the joint.—*The Lancet*, May 29, 1875.

DILATED HEART FROM VALVULAR LESION; PUNCTURE OF THE RIGHT VENTRICLE BY ERROR; RELIEF OF SYMPTOMS.—At a meeting of the Clinical Society of London, held May 14, 1875, Dr. George Evans related the particulars of the above case. A woman, aged 27, was admitted into the Middlesex Hospital, under his care, on February 22, 1875. She was suffering from rheumatism and heart disease, the latter the result of a former attack of the rheumatism. The area of præcordial dulness was increased, there were murmurs at the apex and base of the heart, and there was considerable dyspnoea. Four days later the dulness was considerably increased, and there was very obvious bulging of the chest-wall; the heart-sounds were muffled and the distress in breathing excessive, threatening immediate death.

On consultation, it was decided to tap the pericardium with the hope of relieving the more distressing symptoms.

Mr. Hulke introduced a fine trocar, to the depth of about half an inch, in the fourth intercostal space, about half an inch to the left of the sternum.

On removing the trocar, a gush of dark blood issued from the canula, and the instrument was felt to be moved in accordance with the action of the heart. The canula was almost immediately withdrawn, not more than about a drachm of blood having been removed. During the operation, no change appeared in the pulse; after it, she said she felt relieved; and that night was the best she had passed since her admission into hospital. For the next few days she seemed better, the dulness gradually diminishing. At the time of operation, she had signs of pleuro-pneumonia of the right lung, and there was some fluid effusion in the right pleural cavity, and later in the left.

After improving in general condition for a week or two, she gradually succumbed to general œdema, four weeks after the operation. It was decidedly the opinion of those present at the operation that the trocar was inserted into the right ventricle. At the post-mortem examination, the heart was found to be extremely enlarged, with an universally adherent pericardium, the adhesions being evidently of considerable age. The interest in the case lay in the fact that the (presumed) puncture of the right ventricle not only led to no ill results, but apparently gave temporary relief in a perfectly hopeless case; and it also illustrated the difficulty of diagnosing between pericardial effusion and an extremely and rapidly dilated right heart.

No cicatrix in the substance of the heart or on the inner wall of the ventricle could be found.

Mr. Hulke said that there was no doubt that the trocar entered the heart. Another time, he said, he should prefer to connect the needle with some kind of exhausting chamber, and to push it in very slowly; one might then stop immediately fluid appeared.—*British Medical Journal*, May 29, 1875.

DOUBLE FISTULA IN ANO; TREATMENT BY THE KNIFE AND ELASTIC LIGATURE.—At a recent meeting of the Clinical Society of London, Mr. Maunder reported the above case, as a test of the relative value of the elastic ligature, recommended by Mr. Allingham, as compared with the knife. The patient was a female, twenty-four years of age, in whom a fistula had formed in the right side of the anus from abscess of the buttock, and a year later a similar one formed on the left side. The two sinuses were almost exactly alike, both as regards position and direction, and therefore well adapted for the comparative trial. The right was laid open with the knife, and dressed with oiled lint, and the left treated with the ligature. On

the ligatured side there was much pain, but scarcely any on the right side, the knife wound healing rapidly. The ligature came away on the ninth day, leaving a wound with callous prominent edges, which did not cicatrize until five weeks after the side treated by the knife, although in the latter the lint had been left in place forty-eight hours longer than usual. Mr. Maunder believed that the ligature should only be used in those cases where there is objection to a cutting operation, and in those who are the subjects of a hæmorrhagic diathesis.

In the discussion which followed, Mr. Heath said that where the fistula was seated high up, in order to avoid hæmorrhage, it would be more prudent to use the elastic ligature or a similar method, e.g., Mr. Luke's (the use of an ordinary ligature, daily tightened). Mr. Hutchinson could confirm Mr. Maunder's statement as to the slowness of healing after the use of the ligature. Mr. Hulke had never used the ligature himself, but had seen it employed in three cases, but the extreme pain and the slow progress made in each case had convinced him of the inferiority of the method.

Mr. Thomas Smith had twice tried the elastic ligature, the result being that he would never resort to it again, unless prevented by very good reasons from using the knife.—*The Lancet*, June 5, 1875.

VERRUCA SENILIS.—Under the name of verruca senilis Neumann describes an affection of the skin peculiar to old people, showing itself in the shape of numerous wart-like tumors on the back and breast. These are of a rusty brown or black color, and may become excoriated and ulcerated from the friction of the clothes. They are composed of layers of accumulated epidermic cells, formed upon a smooth surface, or upon the remnants of the papillæ. Under the microscope the epidermis shows nothing abnormal, the rete Malpighii is shrunken, and it and the adventitia of the vessels show an accumulation of pigment in their cells, while the hair-follicles have become rounded formations, containing horny cells, smegma, and woolly hairs. The sebaceous glands are enlarged and filled with a dried secretion from their orifices being closed so that they also resemble pale-red, wart-like tumors. Verruca senilis is distinguished from the common wart by its not involving the papillæ, but only the epidermal tissues, whence the propriety of the name keratosis pigmentosa. The treatment recommended is green soap, or painting with iodine in glycerine, or with a dilute solution of carbolic acid, or they may be scraped away with Daniell's spoon.—*Wiener Med. Presse*, No. 13, 1875.—*Berl. Klin. Woch.*, May 24, 1875.

OVULATION WITHOUT MENSTRUATION.—At a late meeting of the Obstetrical Society of Edinburgh, Dr. James Young mentioned the following interesting case as an example of ovulation without menstruation. The lady referred to was married on the 13th of June, 1867, at the age of twenty-five years. She menstruated on the 13th of July, and her first child was born on the 4th of April, 1868. The patient stated that she nursed the child thirteen months, and then menstruated six times—till November, 1869. The second child was born on the 15th of August, 1870, was nursed five months, when the baby died. From November, 1869, until January, 1875, the patient had never menstruated; during that period a third child was born, 31st October, 1871, while a fourth child was born on 12th September, 1873, and a fifth pregnancy was then going on, each child having been nursed twelve months.—*Obstetrical Journal*, Apr. 1875.

SPECIALISM AS A PRACTICE.

THE success of specialism has turned the heads of half the rising generation of medical men. It seems with them to be an accepted fact, that not to be a specialist of some sort is to be nothing. The consequence is, the ranks of specialism are already very much crowded. The different departments of the grand army of medicine are so well commanded that we are getting more officers than men. Specialism, like every other good thing, is well enough in its place; but when it is liable to swallow up every other interest in medicine, the enthusiasm which begets such a disposition stands in need of some reasonable check. A quarter of a century ago a devotion to the study of a particular branch in medicine met with such opposition, that ostracism from the profession was one of the mild means of punishment proposed; the right of representation in the American Medical Association was questioned; in fact, the exclusive practice of a specialty was considered such a violation of the principles of scientific medicine, that the one who dared to defend such a course risked his reputation for respectability, and invited aspersions upon his professional integrity. This was one extreme which prepared the way for the reaction which is now upon us.

Specialism, as a study, has been of an incalculable benefit to scientific medicine in stimulating investigation, in enlarging our means of observation, in perfecting our knowledge of diseases previously but little understood, and in rendering more exact our methods of treatment. So far, so good. On the other hand, however, it has encouraged a spirit of transcendentalism, which has had a marked and dangerous antagonism towards the best-directed efforts of pioneer investigators. It is not our purpose, however, to discuss the relative merits of specialism and general medicine at this time, but to refer more particularly to some of its effects upon general practice.

The practice of a specialty being considered the

sine quâ non of success, it is perfectly natural that numbers espouse the course. One of the conditions of such a course is the exclusive devotion to the particular branch of medicine that is chosen. As very often happens, when the enthusiasm gets the better of judgment, when the proper relations of demand and supply are not carefully considered, we sometimes have more workers than work. We may not have arrived at that point as yet, but we are certainly near enough to it to view the situation from a common-sense standpoint. Already a failure to succeed is being foreshadowed to some of the most enthusiastic devotees of specialism, and we shall not wait very long to see this number increasing. The fact is, the field is very limited; necessarily it must be so. These gentlemen have to depend, for the most part, upon consultation with their medical brethren; and unless the specialist has a transcendent reputation his chances of such patronage are not very encouraging. A few of the leading specialists get all of the best cases, receive the largest fees, and, consequently, prosper pecuniarily and professionally; while those of lesser reputation, whether equally capable or not, must be content with what they can get.

One of the natural consequences of such a condition of things is, a determination to get the desirable reputation. This is certainly a very laudable object, and if it did not affect any other interest than that of the general progress of our art, it would be well. The difficulty, however, is that the personal element enters too largely into the struggle. Facilities for study and experience must be obtained at any cost, college clinics must be supported, patients must be secured for private dispensaries, and interesting cases must be treated for nothing, if they cannot be procured otherwise; papers must be read before societies, for the purpose of informing the general practitioners of the progress made in a particular branch, and of impressing them with the idea of the capabilities and experience of the writer. All of these means are considered legitimate, and are, consequently, tolerated. But it is one thing to supply a demand and another thing to create a demand. The latter is certainly the hardest part of the task which the struggling specialist now takes upon himself. It is with him such a primary consideration that everything must bend to it. If we view this matter in reference to its effects upon the general practice of medicine, we have much food for reflection. We believe it to be a perfectly legitimate conclusion that the specialists are increasing far beyond a reasonable demand for their services; that in the majority of instances a great deal of very desirable talent is drifting, pecuniarily and professionally, to a very unprofitable account. The struggle, too, to develop opportunities for success is oftentimes liable to sacrifice other and more important interests. For instance, the multiplication of medical charities and their consequent abuse is more or less chargeable to a determination to develop specialties. The eager-

ness to obtain a particular class of patients is oftentimes so great that not only are medical services bestowed upon people well able to pay for them, but a premium is offered to them for the privilege. This is an old story, but a true one; and many of these progressive gentlemen are unconsciously doing an irreparable injury to their brethren, by cheapening medical services for the purpose of gaining an increased experience. In many instances their capital is drawn from the livelihood of such of their brethren as are expected to support them by consultations.

Again, not only is talent, in many cases, misdirected, but the legitimate claims of general practice are ignored. In fact, if this fashionable tendency continues, we shall by-and-by look in vain for the good old family practitioner. And, after all, is it not time that some of the professional energy that is wasting, in the expectancy of a more substantial success in specialism, shall be turned in the direction of general practice?

RELIGION AND SCIENCE.

A SECT called "The Peculiar People," are just now attracting considerable public attention in Great Britain on account of a belief which they have in regard to the efficacy of prayer as a curative agent, they having held to their doctrine to the exclusion of more material aid in the shape of legitimate medication. A number of these misguided enthusiasts are now awaiting trial in England on commitment for manslaughter, for not calling in medical aid when members of their body were sick. It is alleged that numerous deaths have occurred in consequence of this neglect, and hence the charge of wilful crime. But what is stranger than all is, that this sect has resolved to put to practical test the question whether medical aid is really a necessity, or whether prayer is not sufficiently efficacious in all cases of sickness. We are all willing to admit the aid which moral treatment affords in the healing of the sick, but we are not yet ready to trust to it in the reduction of a dislocation, the delivery of a fetus through a contracted pelvis, or in any other of those emergencies which sometimes cause anxiety to the most expert practitioner. "The Peculiar People" appear to be willing to argue the question, and the points which they make will at least have the charm of originality.

THE HARLEM FLATS.

The utility of agitating a sanitary question, and the results growing out of it, are exemplified in the recent decision concerning the Harlem Flats nuisance. The protests of the Medical Faculty of that neighborhood, and the solicitations of the Board of Health, have been rewarded by an appropriation of over twenty-one thousand dollars for the proper filling in of these lots. This is hardly half of the amount asked for by the Health Board, but it is sufficient for a good beginning.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 26th, 1875.

DR. F. DELAFIELD, PRESIDENT, in the Chair.

ANOMALOUS DISEASE OF THE STOMACH.

DR. DELAFIELD presented a stomach removed from a patient who was admitted to Bellevue Hospital on one day, and who died the next. Nothing could be learned of her previous history. Her most marked symptom was vomiting. The house-physician had succeeded in making a correct diagnosis, but upon what ground it was not known.

At the autopsy the peritoneal cavity contained a large amount of pretty clear serum, while the peritoneum everywhere was considerably thickened, the result of chronic bronchitis. The stomach was very much altered, its walls being much thickened, particularly posteriorly. Close to the œsophageal orifice was a tumor as large as a hen's egg projecting into the cavity of the stomach. The surface of this tumor presented no marks of ulceration, nor was there any ulceration in any part of the mucous membrane of the organs. There were no enlarged glands in the neighborhood of the stomach, no secondary tumor in the liver, nor anywhere else in the neighborhood. The disease was limited entirely to the stomach, and was of a character very difficult to name and classify. The microscopical examination showed a new growth to be almost entirely composed of connective tissue. There are cells present, but not in any great number; some polygonal cells as in true cancer, but no characteristic alveolar arrangement, and no ulceration.

Dr. Delafield remarked that he had met with this form a number of times, and although he had been accustomed to calling it cancer, he nevertheless had doubts as to whether that name was applicable. An additional reason for this belief is, that there are no secondary tumors. Yet, on the other hand, we should remember that we find cancer in other regions in which we cannot say that we find any cancerous structure, but in which all the other characters of the disease are present.

PYÆMIA.

DR. JACOBI presented a specimen removed from a woman who had been a patient of Bellevue Hospital. She was admitted, a number of weeks ago, with erysipelas of the face, for which she was treated with local applications of carbolic and oleic acids. After her recovery from this she had another attack, which spread to her scalp, and was attended with abscesses in that locality, and also in the right axilla. Incisions were made and a considerable amount of matter evacuated. From that time a large number of abscesses appeared in the scalp, and were duly opened, the after-treatment, as in the axillary abscess, consisting of local applications of carbolic acid. When the abscesses were opened in one locality they would make their appearance in another, clearly indicating that they were due to pyæmic influences. After the second attack of erysipelas had entirely disappeared, and her temperature had gone down, she had a third attack, which lasted a considerable period. The local application of carbolic and oleic acids prevented the spread beyond its seat in the face. At that time the first deposit of pus was noticed in the neighborhood

of the left knee. A few days afterward a soft swelling was found in the neighborhood of the right knee, and a few days after in the neighborhood of the right elbow-joint. Thus the diagnosis of pyæmic poisoning was corroborated.

During each of her erysipelatous attacks her temperature ranged from $104\frac{1}{2}^{\circ}$ F. to 107° F.—indeed, she bore this high temperature for a very long period, despite the free administration of quinine, salicylic acid, and tincture muriate of iron. Nothing except cool bathing seemed to have any direct influence upon that symptom.

She died May 25. At the autopsy abscesses were found in the scalp, right axilla, in both knee-joints, also in right elbow-joint. No pyæmic abscesses were found in the uterus. On incising the right ovary a cyst was found containing a quantity of decomposed blood. The left ovary also contained a cyst of smaller size, filled with a yellowish liquid. It appeared that a large part of the ovary was used to make up the cyst. Both these cysts seemed to be the results of rupture of the Graafian follicles in the interior of the ovary.

There were also a few cysts found in Douglas's cul-de-sac, attached to the peritoneum, and in the immediate neighborhood of a few large blood-vessels. Dr. Jacobi thought that these cysts might have resulted from localized inflammation, causing fibrinous deposits, and that the exudation might have taken place underneath them, in the same manner as cystic formations will take place in consequence of repeated attacks of pachymeningitis. It might also be possible that the epiploic appendages were deprived of their fat, and in its place the effusion had taken place.

EMBOLISM.

DR. JACOBI presented some specimens removed from a man who was in Bellevue but a few hours with all the objective and some of the subjective symptoms of pleuro-pneumonia. At the autopsy there was found extensive pneumonia, empyema, and a thickened pleura. In the other lung there was an immense hemorrhagic infarctus in the lower lobe. Nothing was known of his history. The only old lesion that could be found upon him was a small ulceration a little behind and above the internal malleolus of the right foot. The valves of the heart were perfectly sound. In the spleen was an immense infarctus of a more recent date than that found in the lung. The liver showed a large infarctus, evidently of a later date, it being in an advanced stage of decomposition. In the absence of another cause for embolism, he was inclined to name the ulceration over the ankle. He had seen cases where local abscesses might give rise to pyæmic poisoning.

DR. MASON referred to a case which had occurred when he was house-surgeon in Bellevue, and in which pyæmia occurred in a case of delirium tremens from a slight ulceration on the leg.

DR. DELAFIELD remarked that it was often very difficult to say where an embolism had its origin, as it was not possible to examine every vein in the body.

Adjourned.

NEW YORK MEDICAL LIBRARY AND JOURNAL ASSOCIATION.

Stated Meeting, June 11th, 1875.

DR. E. R. PEASLEE, PRESIDENT, in the Chair.

DRAINAGE.

THE Association listened with interest to remarks made by Gen. Egbert L. Viele, upon the subject of drainage. He had been announced to read a paper upon "House Drainage," but he purposely avoided confining himself to this particular topic, as it bears about the same relation to the general subject of drainage as the space occupied by a fly does to the subject of the globe. The speaker started with the proposition that saturated soil is the principal cause of preventable diseases, and the great element which physicians (especially of this city) have to contend with in their practice. The New York Association of the Board of Health would limit the subject of drainage almost entirely to the work of the plumber, but the field is much wider, and drainage has to do with the dryness of the soil exterior to the premises and also in the cellar. Confining his remarks to the city of New York, the speaker traced upon a map the old water-supplies, swamps, ponds, etc., upon the island, and demonstrated that in many instances these ponds and swamps had been filled, and natural water-courses obstructed, without making proper provisions, indeed no provisions at all in many instances, for drainage. It is an idea which he had found entertained by very many well-informed people that sewerage and drainage are one and the same thing, and that all the drainage necessary can be done by the ordinary sewer. This is a mistaken idea, and he proceeded to demonstrate that, in nearly every instance, the level of the water-courses upon the island is far below the sewer level, in some places as many as twenty feet, rendering it absolutely impossible for the water retained in the soil when these courses are obstructed to be carried off by the sewers. The result has been from obstructing these natural water-courses, which in many instances have their rise in perennial springs, that the soil underneath the houses, in many of the most wealthy portions of the city, is saturated, and is a constant source of disease.

The condition of the Harlem Flats was commented upon at some length in terms of the greatest earnestness and severity, and the opinion expressed that if there ever was reason for a Vigilance Committee there is reason for raising one at the present time, stirring up those men who insist upon filling up these streams without proper drainage for avoiding saturated soil. With regard to those houses which are situated over water-courses having a lower level than the sewers, they are always dangerous to live in. These houses should be supplied with pumps to raise the water from the cellars into the sewer, and in that way they can be made safe dwelling-places.

Cast-iron is the only material fit to be used for soil-pipes. The soil-pipe should always have a ventilation-pipe running parallel to it, connecting with the traps in the soil-pipe upon every story, and should extend to the roof of the house.

With regard to the construction of the water-closet itself, the pan-closet, the one in common use, has certain disadvantages. First, the pan is emptied at an angle and the discharge is against the side of the receiver, and there accumulates a quantity of matter which in turn becomes a source of disease. In addition, the pan itself is not always clean, and when it goes back it strikes the bottom of the closet, and there

MICHIGAN UNIVERSITY.—The Regents of the Michigan University, on the 29th of June, appointed George E. Frothingham, Professor of Ophthalmic and Aural Surgery, and W. J. Herdman, Demonstrator of Anatomy. At the thirty-first commencement, the degree of Doctor of Medicine was conferred upon twelve male and one female graduate.

lodges a quantity of faecal matter each time. In this way there is constant danger of an accumulation of matter which is destructive to health. These disadvantages, the speaker explained, can be removed by a simple attachment, consisting of a pipe arranged under the bowl and around the exterior of the pan, for the purpose of washing the interior of the receptacle and the exterior of the pan and bowl, and at the same times keeping the lower traps properly supplied with water. The water is discharged from this pipe in jets.

In answer to some questions, the speaker remarked that sewer gas is forced into our dwellings under certain states of the atmosphere, and to overcome this thorough ventilation of the sewers should be established, which can be done by erecting sewer-shafts having induced currents of warm air within them. Such induced currents are readily established by means of gas-lights in the shaft.

A vote of thanks was extended to Gen. Vié for his interesting discourse, after which the Association adjourned.

Correspondence.

HOW TO PREVENT MISTAKES IN PRESCRIBING AND DISPENSING MEDICINES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The question has often suggested itself to my mind. In what way can the physician and druggist insure the utmost possible safety to the patient in taking the medicine that the one has prescribed and the other prepared? It is, of course, the great desideratum of physicians in prescribing, and in the druggist in compounding, to have the prescriptions accurately and *safely* prepared; but in many cases it does not by any means follow, that because the prescription is accurately prepared, that it is safe to administer the medicine as prescribed. It often occurs that a prescription which has been prepared strictly according to the directions of the physician, would be attended with unhappy, and perhaps fatal results if administered to the patient. The principal object of the physician, the druggist, and the patient is to have the medicine prepared with the greatest care from the best and purest material, and when that has been done, the functions of the druggist cease, and he has apparently no farther connection with the case; yet, if any error has been made by the doctor, either by overdosing or by ordering the wrong article in prescribing, and harm comes therefrom to the patient, the druggist is equally held to blame, although he may have dispensed exactly as the physician directed, who alone should be held responsible, *unless* he, in prescribing, wrote the directions on the prescriptions, thereby showing the druggist just how the medicine was to be used, and in what doses, thus giving him an opportunity to correct whatever errors the physician may have made in the prescription. The druggist who would dispense a fatal or overdose in such a prescription would be much more to blame than the physician who ordered it, as such a case would be the result of either his own gross ignorance or carelessness. Now, in order to prevent as far as possible all errors, what system or plan is there in prescribing, which, if adopted by physicians, will be most conducive to the mutual safety and protection of the three

parties concerned, viz., the physician, patient, and druggist? Having had considerable experience in dispensing, and being daily called upon to scrutinize a large number of prescriptions, I can safely say, as a practical result of such experience, that the nearest and most complete approach to perfect safety attainable by human foresight and care, is by the physicians plainly writing on each prescription the directions for its use. By using this simple caution any competent druggist in dispensing the medicine would see at a glance if an error, either in overdosing or in giving the wrong article, had occurred, and would be able to remedy it. In fact, a good druggist will guarantee the physician against *all* errors, provided the directions accompany each recipe. Indeed, the physician, wearied by his labors, and harassed by his cares and great responsibilities, has a right to expect of the druggist such caution and vigilance that all mistakes will be detected and corrected; but in order to do this he must have the directions for the use of the medicines.

Many physicians, in prescribing the most powerful and dangerous remedies, merely give verbal instructions to the patient or nurse, simply directing the druggist to label the medicine, "Use as directed." This is a dangerous practice, and much harm is liable to result from it. In such cases the druggist, not knowing how the medicine is to be used, is powerless to prevent evil; and if the physician has made an error in writing his prescription, injury, and perhaps death to the patient follows, all of which might have been avoided by simply writing the directions on the prescription.

To illustrate the foregoing remarks, I append several prescriptions that have come under my personal observation. A lady brought to my pharmacy the following prescription: R "Acid Hydrocyan Dil $\frac{5}{j}$." "Sig use as directed." The large quantity called for of such a powerful poison first excited my suspicion, and on questioning the patient as to how it was to be used, she replied that she was to take thirty drops of it three times a day in water. Telling her that it would take some time to prepare the medicine, I sent the recipe to the physician, who immediately destroyed it, and wrote instead, "Acid Hydrochloric Dil." If I had dispensed this without inquiry, or sending it to the doctor, death would have resulted from its use, and I certainly would have been to blame, for under no circumstance should a druggist dispense such a dangerous medicine, without first positively knowing how it is going to be used. This recipe was brought in by a servant for dispensing:

℞ Bismuth subnit..... gr. x.
Morphine sulph..... " ij.
M. ft. pulv.

With no directions and no signature, I could get no information as to how it was to be used; and fearing that it might produce fatal results if taken in one dose, I refused to dispense it. I afterwards learned that the physician was very angry with me, and that he sent the prescription to another store, where it was dispensed. Thus, by my caution, which perhaps in this case bordered on timidity, I lost the good-will of the doctor; but it was so easy to assure the positive safety of the patient, that for that purpose I felt justified in returning the recipe for revision, but unfortunately for me the physician thought that I exceeded my duties.

In emergent cases physicians often prescribe heroic doses of powerful medicines, and the apothecary, not knowing under what circumstances the prescription was written, is afraid to dispense it, and sends it back to the physician for revision. In this way not only much valuable time is lost to the patient, but the phy-

sician is often offended. It would be but strict justice to all parties if the physician alone was held responsible for his prescriptions, provided, of course, that they are dispensed strictly as ordered; but unfortunately for the druggist, an unthinking public holds him equally responsible for all mistakes, without knowing or caring whether they are his or the physician's, consequently the druggist, in order to preserve his own reputation and to insure as far as possible the safety of the patient, has to be exceedingly careful, even at the risk of offending the physician. The following prescription, it will be observed, bore the directions for its use:

R Potass bichrom. ʒ ij.
 Aq. pura. ʒ ij.
 M. ft. mist. Sig. Teaspoonful every two hours.

Intuitively I knew that this was wrong, and turning to the dispensatory I found that the dose of bichromate of potash was one-eighth ($\frac{1}{8}$) of a grain once a day. On sending the prescription to the physician, he crossed out the word bichromate, and wrote bromide instead. In this case, by my caution, which with all druggists becomes habitual, I saved a delicate invalid from great injury, and probably death.

I will give but one more illustration. I dispensed this recipe, together with two others—one a mixture, the other a powder—for a laboring man:

℞ Ext. belladon. fl. ʒ ij.

No directions. I marked it: "This medicine to be used with care," and sent it with the others to his house. By mistake his nurse gave him a teaspoonful of the belladonna. It was only by the great exertions of a physician that his life was saved. If this medicine had been marked "poison," or "for external use," this would not have happened. In this case the doctor had given verbal directions for only this one of the three prescriptions, and it was to be used externally.

Physicians would be surprised to see the vast numbers of errors constantly made by members of the profession in writing their prescriptions. Scarcely a day passes that I don't have to send one or more back for correction. Often the number of pills or powders wanted is omitted, or the quantities of the different materials are not stated, or some other mistake, perhaps slight in itself, but still sufficient to prevent the dispensing of the prescription. To hunt up the physician and get the errors rectified takes time, and in all such cases the patient blames the druggist for the delay in sending the medicine, little thinking that but for his care he might be suffering grievously from the mistakes of the physician. The apothecary, fully appreciating the responsibilities of his profession, and realizing that the health and life of the patient is in his hands, is ever on the alert to detect errors; and today many a patient owes his life, and many a physician his reputation, solely to the ceaseless care and untiring vigilance of the apothecary. Numbers of our best physicians will bear personal testimony to the truth of this statement. The relations existing between the physician and apothecary are much more intimate and confidential than formerly. Both see how mutually dependent each one often is on the other, and both should also see how little consideration is paid either of them, should they by chance make a single fatal mistake. In such cases the public and the press regard them as a common foe. To both physician and apothecary (and probably to the patient also) such an occurrence is very unfortunate; but to the apothecary in particular it is in the highest degree calamitous, and a single fatal mistake will sweep away in a moment the reputation of a lifetime, which

had been acquired only by the hardest work, closest confinement, and most strict attention to business. Besides this, he is cast into prison, his name is published far and wide, and his business ruined. Finally, he is generally mulcted heavily in a suit for damages. In addition to the above, an editor suggested in his paper (*The Express*) that hanging would be a proper punishment for careless druggists who make mistakes, and this suggestion is but a fair reflection of the public feeling on the subject. Therefore it ought to follow, that where the risk is so great and the punishment so severe, the parties responsible should use all human precaution to prevent fatal mistakes, which, once made, will send one of the parties to the grave, and the other to prison and the almshouse. To my mind, as before stated, the best way to secure this desired result is for the physician in all cases to plainly write on each prescription the directions for the use of the medicine. When this has been done, a long step towards perfect safety has been attained; and only the druggist should be held responsible for any error that may occur, either by overdosing or the wrong article being prescribed.

In closing this article I will once more quote from the druggists' friend (*i.e.*, Mr. Brooks), who, in *The Evening Express* of April 13th, in commenting on a recent case which considerably excited the public mind, very forcibly said that, "druggists should not give out any prescription except upon a written order of a responsible physician, and physicians should give written orders as to the use of the medicines they prescribe." This is the whole matter in a nutshell.

Yours, etc.,

T. H. SAYRE,
 Dispensing Chemist.

BROMIDE OF POTASSIUM IN STRYCHNINE POISONING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Thinking the following might be of some interest to the profession, I take this opportunity of presenting it:

Mr. T., a farmer, twenty-five years of age, of temperate habits, while suffering from mental aberration, procured on the 18th inst. twelve grains of strychnia, representing to the apothecary that he wished to poison some rats. Returning home he retired as usual. About five o'clock on the next morning he arose, mixed half the quantity of strychnia in a cup of water, and drank it. His mother hearing him, and mistrusting from some unusual action that all was not right, hastily arose and soon drew from him the confession that he had swallowed "poison" with suicidal intent. I was summoned immediately, first seeing him one-half hour after he had swallowed the potion. I found him in bed, lying upon his back, unable to move his arms or legs, his head drawn back and jaws quite stiff; yet his intellect, so far as I could discover, was perfectly clear. He answered my questions in a manner which led me to suppose he understood them, and said he had taken strychnine. I put my hand upon his head, and immediately there occurred a spasm, resembling the shock one exhibits from a sudden and intense discharge from an electric battery. These shocks or spasms could be produced at will as often as any one touched him, and were repeated from every two to four minutes, whether he was disturbed or not.

Mixing a dessertspoonful of powdered mustard in some water, and adding a drachm of Squibb's fluid extract of ipecac, I succeeded, after some perseverance, in

the midst of successive spasms, in getting him to swallow all of it. Emesis occurred in about ten minutes, the spasms being full as free as the emesis. He drank nearly a quart of warm water. This was also freely vomited. After the vomiting, the spasms still continuing, I gave twenty grains of bromide of potash. He immediately exhibited the most profuse perspiration I ever beheld. I thought him dying. In fifteen minutes more I exhibited another fifteen grains of the bromide. This I repeated every fifteen minutes till one hundred grains had been taken, and the spasms had gradually subsided and now entirely ceased. I ordered the bromide each two hours after, and left him feeling quite comfortable.

On seeing him the next day he complained of nothing but soreness of the muscles generally. Said he felt as though he had been skating on the ice. He recovered from this slowly, and now is apparently as well as before the drug was taken.

My reason for using the bromide instead of the remedies usually recommended was, that it seemed to be the only medicine I had at hand indicated rationally from his condition, having neglected the precaution to take chloroform or ether with me, or other things used to control spasms or to act as an antidote.

From the result of this case I conclude that bromide of potassium may prove to be a serviceable remedy in such cases.

DAVID DANA SPEAR, M.D.

FREEMONT, MD., May 25, 1875.

DR. ANTONIO LUACES.

TO THE EDITOR OF THE MEDICAL RECORD.

MY DEAR DOCTOR:—Some of your readers must have been pained on seeing in a recent morning paper a notice of the execution of Dr. Antonio Luaces by the Spanish authorities in Cuba. A few particulars of his untimely death having reached me, I ask you to publish them, and a word of tribute to his memory will doubtless find a response in many hearts.

Dr. Luaces went to Cuba with General Jordan's expedition, and has ever since been in the medical service of the Cuban army. After the death of General Agramonte, some three years ago, he was made Surgeon-General.

On the 20th of last April, while on sick leave near Puerto Principe, he was betrayed by a spy and was taken into his native city by a guard of Spanish soldiers sent out for the purpose.

As his family was influential there, and as his professional skill had not discriminated between friend and foe, petitions from many sources, especially from benevolent and religious societies, were forwarded to the authorities praying that at least his life be spared. He was, however, shot on the 22d of April, two days after his capture, the only concession to his character and profession being that they fired at his breast instead of at his back (their usual custom with "insurgents"). They say he died bravely, as of course he did, for he was brave by nature, and had chosen his path deliberately. He was buried in the cemetery of the city with the dead of his family.

Dr. Luaces began the study of medicine in the office of Dr. James R. Wood; graduated with honor at the Bellevue Hospital College in 1865, I think; was on the staff of Bellevue for the usual time; spent two years in Paris taking special courses and walking the hospitals, and afterwards went to Spain, and passed a successful examination for his Spanish diploma.

As his advantages had been unusual, so his profes-

sional accomplishments were of the highest order. He was remarkably handsome and manly in appearance, dignified and cordial in manner, sincere in heart, by necessity above all littleness, and a warm and loyal friend.

W. DEF. D.

56 EAST THIRTY-FOURTH STREET.

MEDICAL ADVERTISING.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: It is a common practice in some parts of the country for surgeons to invite to their operations at least one layman, and frequently a number, who invariably report the cases to newspaper men, and in this indirect way advertise themselves as enterprising surgeons, dexterous operators, experts in their profession, qualified for any and everything in their particular line, etc., etc. Comparatively small operations are described as being formidable, and seldom performed except in the older cities, as New York and Philadelphia. Does the above course constitute advertising? To my mind it does, and the man who will pursue such a course, in the opinion of the writer, is as bad, if not worse, because more crafty, than the one who signs his advertisements and pays for their publication. If you do not think this subject already exhausted, by giving these lines a passing notice in *THE RECORD* you may turn some from the error of their ways, and will strike a powerful blow at cunning (?) advertising in some parts.

M. D.

NEW YORK CITY, June 12th, 1875.

ALIMENTATION IN INTESTINAL DISORDERS OF INFANTS.

TO THE EDITOR OF THE MEDICAL RECORD.

MY DEAR DOCTOR: In *THE RECORD* of June 5th (No. 239) you did me the honor of publishing a very full report of a paper which I read on May 13, 1875, before the Medical Library and Journal Association, on "The Relation of Alimentation to the Gastro-intestinal Disorders of Infants and Young Children." Excellent as the report is, especially considering that the reporter had no access to my manuscript, yet a few errors have crept in, which, though I wish they had not occurred, I yet will not trouble you by asking a correction of all of them, but only of the two subjoined, which, if left as at present, accredit opinions to me I do not wish to father. Page 395, 1st column, 13th line from the top, should read, "absolute rest for six, ten, or even twelve hours."

Again, on same page, 2d column, 2d paragraph, 7th line from top, should read, "it is *erroneously considered* altogether dependent upon that process." As my paper will appear in full in the August issue of *The American Journal of Obstetrics*, etc, I would refer such as may desire to read it, to the latter journal.

With regard, very truly yours,

B. F. DAWSON.

8 E. 15TH STREET, June 25, 1875.

UNIVERSITY OF PENNSYLVANIA.—At the Commencement of this University, on the 24th of June, the Honorary Degree of Doctor in Medicine was conferred upon J. Sartoris Giltner, and W. Paris Dale Giltner, and the following Doctors in Medicine received the additional Degree of Doctor of Philosophy:—B. Franklin Lautenbach, Harry M. Stelwagen, Louis E. Gilliard, J. A. Ogden, Andrew McFarlane, A.M., R. S. McCombs, William H. Winslow, and F. A. Hassler.

HOSPITAL APPOINTMENTS.

TO THE EDITOR OF THE MEDICAL RECORD.

Sir:—If it is true, as "Veritas" claims, that the hospital appointments are for the honor and profit of a few favored professional men only, the time is ripe for a reform. It appears a plan might be devised whereby the advantages of hospital practice and experience could be made available to all the members of our profession. To make my idea more plain, why cannot it be so arranged that the regular societies will govern the medical and surgical appointments—open to any member that may choose to accept. Some would not care to serve, others would, and the junior physician and surgeon could serve at the same time with the senior. If it is objected that they may not be qualified, as is sometimes urged, they certainly are as qualified to practise in a hospital as they are to conduct a private practice, or belong to a medical society. The letter of "Veritas" is very suggestive, and our profession can, if they will, abolish the present unjust system of hospital appointments.

JUSTICE.

BROOKLYN, June 21, 1875.

New Instruments.

AN IMPROVED APPARATUS FOR TORTICOLLIS,

IMPROVED BY JOHN REYNDERS & Co., NEW YORK.

This apparatus consists of a well-padded pelvic band, *a*, to which an upright steel bar is attached at *l*, passing upwards along the spine to the upper dorsal region.

A cross-bar, *c*, is attached to its upper end, passing from one axilla to the other, and fastened to two crutches, *k*, fitting well under the arm. These are connected to the pelvic band by two lateral bars, *m*,

which, by means of a slot and screw, can be raised and lowered somewhat at will. The part of the apparatus so far described is applied firmly to the trunk by means of straps passing over the shoulders and fastened to the axillary cross-bar at *e*, *e*.

A firm hold of the head is secured by a pad (sheet steel inside) reaching almost from the eyes backwards around the skull, with apertures for the ears, and fastened to the head by straps over the forehead and under the chin. To its back part a steel bar is riveted, *d*, which connects the upper part of the apparatus with that applied to the trunk. The lower end of this steel bar is ratcheted, and is adjusted in a slide at the upper end of the steel rod passing up along the spine, and held in a desired position by a thumbscrew, shown on the figure near the letter *h*. This connecting bar is intercepted by three different joints, *e*, *f*, and *g*, by which flexion can be made in any direction, when worked with a key. At the joint, *e*, rotation, at *f* flexion forward and backward, and at *g* flexion to the right and left, can be made.

The advantage of this apparatus over many others lies in its characteristic point, namely, that firstly a firm hold is secured to the head and trunk, and that then the head can be brought in the proper position by a true and irresistible mechanism. When worn it is almost entirely hidden by the clothing, and patients cannot very easily withdraw themselves from its action.

Apparatus similar to this have been made before, but never with all the features of a torticollis brace combined on one apparatus as in this case.

ELASTIC CLAMP FOR SECURING THE FUNIS.

By EZRA R. PULLING, M.D.,

NEW YORK.

THE possible occurrence of hemorrhage from the umbilical cord, through loosening of the ligatures, is frequently a source of anxiety to the accoucheur, when he leaves his patient after delivery. Accidents from this cause, if not very frequent, are yet sufficiently for-

midable to give importance to effective means by which pressure on the cord may be rendered constant under all circumstances. Having this end in view, I have devised an elastic funis clamp, made of a single strip of thin steel doubled on itself, and shaped as shown in the cut, which represents it enclosing a section of the funis. Through the skill of Messrs. Tiemann & Co. it has been rendered safe, effective, simple, and cheap. The opposed surfaces being convex, the pressure is nearly as great when they are approximated as when the separation is considerable. It is clasped and unclasped by sliding the extremities of the arms at *b* past each other.

I have used one of these little instruments in about twenty cases, and it is still in good order. I generally remove it on my second visit, when I find the cord beneath it compressed to the thinness of paper, and the

vessels perfectly obliterated. It is very convenient, besides giving such a sense of security that I should be very unwilling to do without it now. Two or more clamps should be carried, one being used to apply temporarily to the placental end of the funis.

April 22, 1875.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from July 4th to July 10th, 1875.

COOPER, GEORGE E., Surgeon.—Granted leave of absence for one month and fifteen days, with permission to go beyond the limits of the Division. S. O. 79, Mil. Division of the Pacific, June 25, 1875.

STARROW, S. A., Assistant Surgeon.—Assigned to duty at Benecia Barracks, Cal. S. O. 63, Department of California, June 23, 1875.

MATTHEWS, W., Assistant Surgeon.—Assigned to duty at Alcatraz Island, California. S. O. 63, e. s., Department of California.

The following promotions and appointments in the Army of the U. S., made by the President, are announced:

II. APPOINTMENTS. *Medical Department.*

To be Assistant Surgeons, with the rank of First Lieutenant, to date from June 26, 1875: BLAIR DABNEY TAYLOR, of New York; CURTIS ETHELBERG PRICE, of California; JAMES CHESTON WORTHINGTON, of Maryland; HENRY STUART TERRILL, of New Mexico; EDWARD TIPPIN COMEGYS, of Ohio; WALTER REED, of Virginia; HENRY SAYLES KILBOURNE, of Indian Ty.; JAMES CUSHING MERRILL, of Massachusetts; WILLIAM RICHARDSON HALL, of Missouri; RICHARDS BARNETT, of Mississippi; GEO. HENRY TORNEY, of Maryland; LOUIS WILLIAM CRAMPTON, of Pennsylvania; JOSEPH YATES PORTER, of Florida; MARSHALL WILLIAM WOOD, of Illinois; MARCUS ELVIN TAYLOR, of New York; WILLIAM LANDS NEWBANDS, of California; JOHN DE BARTH WALBACH GARDINER, of Maryland; ROBERT E. SMITH, of Missouri; WILLIAM CUMMINGS SHANNON, of New Hampshire; GEORGE EDWIN LORD, of Maine; LOUIS S. TESSON, of Missouri; WILLIAM GARDINER SPENCER, of New York; ROLAND LEE ROSSON, of Virginia. G. O. 69, A. G. O., July 2, 1875.

DUNGAN, J. S., Medical Inspector.—Ordered to the *Brooklyn*, South Atlantic Station.

BATES, N. L.—Detached from the *Brooklyn* and ordered home.

DICKSON, SAMUEL H., Assistant Surgeon.—Detached from the Naval Hospital at Philadelphia, and ordered to the South Atlantic Station.

WELLS, HOWARD, Assistant Surgeon.—Ordered to the *Worcester*.

WAGONER, JAMES P., Assistant Surgeon.—Detached from the *Worcester* and ordered to the Naval Hospital at Norfolk, Va.

STREETS, F. H., Assistant Surgeon.—Detached from the *Narragansett* and awaiting orders.

Medical Items and News.

THE PECULIAR PEOPLE.—This sect, a number of whom are awaiting trial in England, on commitment for manslaughter for not calling in medical aid when members of their body were sick, have resolved to put to practical test the question whether medical aid is really a necessity, or whether prayer alone is not sufficiently efficacious in all cases of sickness. For some time a large twenty-roomed house, situated in Tower Street, on the north-east side of London Fields, formerly used as a homœopathic hospital, has been secured, and the following placard, posted on a large board, displayed: "House of Faith for the Reception of such Sick as are considered Hopelessly Incurable, to be Healed by the Prayer of Faith." This inscription is followed by numerous texts of Scripture.

DANGEROUS COMPOUND.—*The Pharmaceutical Journal* of Vienna states that the following prescription was sent to a pharmacist: Chromic acid, eight grains; glycerine, one drachm. For external use. The dispenser dissolved the acid with a little water in a phial by a little shaking; the glycerine was then poured in, and the phial again shaken. Thereupon the compound exploded with a very loud report, and was projected with force to the ceiling of the shop. The phial, which did not break, became coated with a black pigment, and remained in the hand of the frightened dispenser. The case deserves attention from the fact that the ingredients were in such small quantities and the explosion so powerful.

DR. JOHN P. GRAY, Superintendent of the New York State Lunatic Asylum, at Utica, has been appointed Professor of Psychological Medicine and Medical Jurisprudence in the Bellevue Hospital Medical College.

DR. RUSSEL REYNOLDS AND THE "PRINCE IMPERIAL."—A report, started by the *Globe*, is going the rounds of the papers, that Dr. Reynolds was rescued from an impending accident from the running away of his horse on Blackheath by the interposition of the young Napoleon, who seized the horse by the head, and, at the expense of being dragged in the mud, stopped him, and prevented the doctor being thrown off an embankment. Dr. Reynolds says that, so far as he is concerned, he knows nothing of the occurrence described.

DEMARQUAY, the celebrated French surgeon, died on Wednesday, June 23d, of cancer. Surgery is greatly indebted to his ingenuity and talent for the invention of many valuable instruments and operative procedures. During the siege of 1870-1871, Demarquay acted as chief surgeon to the ambulances. He had amassed a large fortune during his professional career, and at his death bequeathed 100,000 francs to the Faculty of Medicine for the purpose of founding an annual prize; 10,000 francs to the friend charged with the publication of his works; the books, pictures, and works of art in his apartment in the Rue Taitbout were distributed as souvenirs among his pupils; and his other property, including his estate at Longueval and 800,000 francs in money, was left to his brother.

VIERLING KERSEY, M.D., died at Richmond, Indiana, June 3d, 1875, of peritonitis. Dr. Kersey was a highly esteemed member of the profession, and had held prominent positions in the medical societies of his County and State, being president of the latter in 1866. He was a native of Guilford County, North Carolina, where he was born September 8, 1809.

Original Lectures.

THE GENERAL PHYSIOLOGY OF THE MOVEMENTS OF THE BODY.

By J. W. S. ARNOLD, M.D.,

PROFESSOR PHYSIOLOGY UNIVERSITY MEDICAL COLLEGE, N. Y.

Phonographically reported for THE MEDICAL RECORD.

LECTURE III.

GENTLEMEN:—At my last lecture I demonstrated that there is in muscle and nerve an electric current which continues to act as long as the muscle or nerve remains in a living and perfectly healthy condition. So long as the chemical and anatomical integrity is preserved, this current is present, and can be demonstrated. In some of the lower animals there is a special apparatus for generating electricity. This apparatus serves two purposes; first, for the defence of the animal; second, for the capturing of its prey. This electrical apparatus is found particularly in fishes. Among the varieties the torpedo is quite celebrated. There is also the gymnotus (electrical eel), and others. The torpedo has upon either side of the head an apparatus which is situated between the skin of the dorsum and abdomen, and consists of two kidney-shaped bodies. These bodies are made up of from 400 to 1,000 prisms; and these prisms are each subdivided into about 2,000 plates. In this manner there is formed a natural galvanic battery of great power. Between the plates is a considerable quantity of albuminous fluid, and to the under surface of the plates pass a large number of nerve-fibres, arising from two sources. Three or four branches come from the pneumogastric and one from the trigeminus. These nerve connections seem to be necessary to the production of the shock. The shocks are of considerable power; for it has been stated by Humboldt that by a single shock from a full-grown gymnotus a large horse can be killed instantly. If the nerve supply to this natural battery be cut off, it is found that the fish loses the power of generating the shock; but if the distal end of the nerves be irritated a shock can be generated artificially. That this power is electrical is undoubtedly true, for upon applying the galvanometer as a test, a deflection of the needle takes place; furthermore, a spark can be made to pass between two electrodes in communication with the positive and negative elements of this natural battery. When the nerves are exhausted by repeated irritation, or after a series of shocks in quick succession, the fish loses the power of generating any more until a certain time has elapsed. In the same manner, a nerve, if irritated for a certain length of time, loses its power of conducting impressions, as is also the case with muscle, which under similar circumstances loses its power of contraction. When a muscle is placed in the circuit of the galvanometer, at the instant of contraction a curious phenomenon makes its appearance. This can be best demonstrated by what is called the double muscle preparation* (Fig. 1).

I expose a long piece of nerve, leaving its distribution to the muscles of the leg as perfect as possible [preparation made].

If the muscles be vigorous in their contraction, and the nerve conductivity or power of transmitting a stimulus be in good condition, our experiment will succeed. The nerve of *one leg* is lying upon the *muscles of the second leg*. I irritate the nerve of the *second leg* and a contraction takes place, as you see, in the muscles of *both legs* [experiment repeated three times].

FIG. 1.

This contraction is not due to any electric current from the battery used, to excite the nerve, which passes through the nerve of the second leg, down to its muscles, in this way acting as a stimulant to the nerve of the first leg, because very often, if the second nerve be simply pinched, a contraction will follow in both legs at the same time. What does this show? It shows that the instant a muscle contracts its electrical condition is changed; for if the muscle had been upon the cushions of the galvanometer, and the deflection of the needle noted (for the natural electrical current of the muscle), which is constant, upon contraction of the muscle the needle would pass back towards zero. Should a tetanic condition of the muscle occur, the needle would then remain near zero. This shows, then, that the instant the muscle contracts the electrical current becomes modified, and the needle of the galvanometer passes back towards zero, and there is an effect produced through the nerve upon the muscle known as negative variation. The secondary movement in the second muscle* is called secondary contraction. At the instant of contraction, or series of contractions, another phenomenon may be observed.

I remove the central portion (shaft) of the femur from this frog's leg, so that the bulb of a very sensitive thermometer † may be brought in contact with the largest amount possible of muscle; and place the bulb among the muscles of the leg where the bone is removed. I allow the instrument to remain until the mercury arrives at a fixed degree of temperature. [Experiment made.] The reading is $29\frac{2}{10}^{\circ}$. I throw the muscles into a tetanic condition by exciting the nerve with the induced current [experiment], and we find that the temperature has risen $\frac{1}{10}$ of a degree. Here is another nerve-muscle preparation which I place in the muscle telegraph ‡ with the nerve upon the electrodes of a battery. I close the circuit, thereby passing through the constant current, when a contraction takes place, followed by relaxation. [Experiment.] Keeping

* The double muscle preparation for this experiment was made by separating the muscles from the thigh of a frog, leaving the nerve attached to the muscles of the leg. Two such specimens having been completed the nerve of the one was laid upon the muscles of the other, and the nerve of the first irritated by a feeble constant current.

* That which had its nerve lying across the first muscle.

† Very delicate registering instrument.

‡ Muscle telegraph is a piece of apparatus for the purpose of showing the contractions of a muscle.

the circuit closed there is no motion in the muscle; but, now breaking the circuit, a contraction follows. [Experiment.] So it has been seen that during the period in which the current is passing through a nerve (if there be no variation whatever in the current) there is no movement of the muscle, but upon breaking or making the circuit a contraction takes place instantly. Let us next use the constant current from this small battery,* and employ twenty elements, each of which is about the size of a silver half dollar. [Experiment made on nerve-muscle preparation in telegraph.] A contraction takes place on breaking the circuit only. We diminish the number of elements, and contraction then follows on closing the circuit only. Hence we conclude that there is a law which governs the action of the current in order to produce contraction. I will pass the induced current † through the nerve. [Experiment.] Notice what occurs. The muscle contracts, and then gradually, or more properly, slowly relaxes, differing materially from the previous contractions and relaxations. This continued contraction is called *tetanus*; it may be produced in various ways. In this instance by the induced current acting upon the nerve.

Should a tracing be taken we would obtain the following form ‡ Fig. 2. The ordinary contraction would

FIG. 2.

be represented thus, Fig. 3. Compare the curve of tetanus. The same quick upward stroke (denoting the rapid shortening of the muscle) is observed, with sometimes greater amplitude, but the curve in tetanus consists of a series of contractions which become fused together, thereby delaying the relaxation. When the muscle is fresh the continued contraction remains for several minutes, but in this case the muscle has become somewhat exhausted from our previous experiments, and therefore the relaxation shows itself rather soon.

FIG. 3.

Tetanus may be produced by simply plunging the nerve into a salt solution, by beating it, by strychnine—in fact, by any means which gives continued irritation to the nerve or muscle. I now have a fresh nerve-

muscle preparation. I dip the nerve into a solution of salt [experiment], and tetanus follows.

We remove the nerve from the solution and allow it to remain undisturbed; the tetanus disappears after a certain time. I dip the nerve once more into the salt solution; you see the tetanus. I now cut off the nerve at the point where the salt is; the tetanus ceases instantly. After a while the muscle loses its power of responding to stimulation (whether the irritant be applied to the muscle itself or the nerve), and is in a condition called exhaustion. If, however, it be allowed to remain quiet for a short time it regains its irritability.

LECTURE IV.

GENTLEMEN:—To-day I wish to demonstrate a very curious law, which leads us to the consideration of all the influences which govern contraction of muscle when the nerve is stimulated. For this purpose I will dissect out a portion of nerve as long as possible, with the muscle attached. [Preparation made.]

What I wish to show you is this: when a constant current is made to pass through a nerve, a peculiar condition is established in the nerve. We already know that while a constant current is passing through a nerve, if the current be perfectly equal and without variation, contraction of the muscle does not occur, and that it only takes place upon making or breaking the circuit. The frog's leg is in this position.*

2. If a current be passed so that the positive pole is in that position (*b* in Fig. 4), and the negative here (*a* in Fig. 4), that is, following the direction of the natural flow of nerve-force, and the circuit closed, there follows a contraction [experiment], and then no action whatever. Upon opening the circuit, another contraction, as you see [experiment], and then rest. Suppose I now place upon the nerve a drop of salt solution, at a point between the muscle and negative pole (*a* in Fig. 4). This irritation causes a certain amount of tetanus. [Experiment.] Close the circuit, here is an increase in the tetanus; reverse the current, † and now the tetanus is diminished and so continues. [Experiment.] I open the circuit, again tetanus makes its appearance. [Experiment.]

This is simply an illustration of one of the variations which takes place in electrotonus. When a constant current is passing through a nerve, the nerve is modified in three ways. Its excitability is modified, as seen in this experiment; its conducting power is modified; its electro-motor power is changed. As is seen by the diagram, when a weak ‡ current is used, represented by the line (so marked), the negative pole presides over the greater part included between the electrodes. With a medium current the positive and negative poles are equally balanced and preside over equal areas. If a strong current be passed through the nerve, then the positive pole presides over the greater area. As the positive pole, or anode, is opposed in its action to the negative pole, or cathode, the condition produced by the positive pole is called an electrotonus,

* A frog's leg, with about two inches of nerve attached, was supported on a stand, the femur being fastened in a clamp, so that the rest of the leg remained hanging down. The nerve was placed across zinc wires in connection with a one-cell bichromate potass. battery. The contraction of the muscles could be distinctly seen, as the foot and rest of the leg moved freely.

† Change the poles by pole-changer. see Fig. 1.

‡ Weak current is obtained from one Grove cell; medium from two or three Grove cells; strong from five or six.

* Trouvé Daniell.
† The induced current was obtained from DuBois-Reymond's induction apparatus.
‡ Tracing made.

while that of the negative is termed cathelectrotonus. Electrotonus consists therefore of anelectrotonus plus cathelectrotonus. With a current of medium strength, when anelectrotonus and cathelectrotonus are equal, that is, when the half of the nerve on the side of the negative pole has its excitability raised, and the half on the side of the positive pole has it lowered, there is a point equidistant from the two poles where the excitability is unchanged, and this is called the neutral point. With a strong current the neutral point approaches the negative pole; with a weak one it comes nearer to the positive.

ance of anelectrotonus. Take the case of a feeble upward current, Fig. 5. Neutral point near + pole, hence cathelectrotonic area is extensive. When the current is closed cathelectrotonus is established at *a*, the nerve excitability is increased, and a contraction of its muscle is effected. On breaking the current, a small portion of the nerve (*b*), near the + pole, passes from anelectrotonus to the normal state, and the nerve is stimulated; the excitability of the nerve, however, is much lowered, from what we have already seen, and therefore the stimulus is too weak to cause contraction.

FIG. 4.

Now, when we have anelectrotonus, that is, when the positive pole is in the ascendancy, then the excitability of the nerve is diminished, as you see. But on the other hand, if we now place the nerve between the cushions of the galvanometer, note the deflection of the needle, first for the normal current [experiment], and then produce the same condition, *i.e.*, anelectrotonus, for the portion of nerve generating the current, we find the electro-motor power is increased, as shown by the deflection of the needle being greater. Reverse the order, produce the condition of cathelectrotonus [experiment], the needle returns to zero almost, thus demonstrating the decrease of electro-motor power. Had we measured the rapidity of nerve-conduction during our experiment just made, we should have found it increased; in like manner is it decreased by anelectrotonus.

If we send a weak current through a nerve in an upward direction, which is toward the spinal cord, from the periphery to the nerve-centre, a contraction of the muscle shows itself upon closing the circuit only. [Experiment.] As the current passes in an opposite direction along the nerve, contraction follows only when the circuit is opened.*

With a medium current we have strong contraction on making and breaking when the direction is upward, and the same thing for downward. What, then, causes contraction? It is, according to Pflüger, due to the appearance of cathelectrotonus, and disappear-

It makes some difference whether the nerve receives its stimulation close to or at some distance from the muscle. As a rule, the greater the distance from the muscle, the stronger the contraction of the muscle. It is supposed that the reason for this is on account of the accumulated force or irritability of the nerve, being greater as the length of nerve increases; so that a stimulus applied close to the muscle would not produce as much effect as the same at a greater distance. More than probable is it, however, that near the nerve-centres the nerves are more sensitive; as nerve-force is generated here, it makes it easier for the nerve-fibres to carry along the impulse. I wish next to demonstrate to you the non-identity of muscular and nervous irritability. We take a frog and introduce into it a small quantity of woorara. The motor nerves are those affected by this poison. Let us galvanize a motor nerve; we try the crural—no effect shows itself; we try the muscle itself, a contraction is the result. A ligature I now place beneath the nerve of another frog's leg, so as to encircle the leg. In this manner the nerve connection remains intact, and the muscles of the leg are separated from the general circulation by the ligature. I inject into the lymph-pouch of the back a rather strong solution of sulphocyanide of potassium. We wait a few moments. I stimulate the muscles of the leg not tied off, *i.e.*, the leg upon which the poisonous sulphocyanide has had an opportunity to act. No contraction. Apply the stimulus to the nerve of the tied-off leg—violent contraction follows. [Experiment.]

* Some physiologists have obtained contraction on closing as well as on opening the circuit; this is not to be explained by Pflüger's law.

From these experiments we conclude that muscular and nervous irritability are distinct properties, and can be separated one from the other; the woorara destroy-

FIG. F.

ing the irritability of the motor nerves, but not interfering with the muscles; the sulpho-cyanide acting upon the muscles themselves, and not upon the nerves.

Original Communications.

STRANGULATED HERNIA REDUCED BY TAXIS THROUGH COLON.

By ALEXANDER HADDEN, M.D.,

NEW YORK.

THE case is as follows: June 13th, 11 P.M., I was called to see Mrs. B—, aged 45 years, the mother of eleven children, a thin, delicate woman of highly nervous temperament.

She was suffering from colic, due to some food she had taken at supper; had not vomited, nor had her bowels moved since morning. I ordered an enema of warm soap-suds to free her colon, and a Magendie's solution of morphia, grt. x., to subdue pain. The injection relieved her bowels, and the morphia, which was repeated twice during the night, eased the pain, notwithstanding she vomited several times after taking it.

June 14, 10 A.M.—She was quite comfortable; had, however, slight nausea and a little pain; called my attention to a lump in her left groin, about the size of a duck egg, which she said had been there before and had gone away, but this time was harder and more painful. I examined it and found it to be a direct inguinal hernia, hard, tender to the touch, and not reducible, notwithstanding my efforts to reduce it were made while she was fully under the influence of chloroform. When satisfied that it could not be then reduced, I applied ice in a bladder to the part, and waited until the morning of the 16th, watching her condition carefully during this interval of time. I made an effort occasionally to put it back, and did several times reduce its size. Her vomiting during the night had been frequent and of greenish color, and

symptoms of strangulation of the circulation of the involved part began to develop. Delay of interference was occasioned by her refusal to have it touched any more, because she was under the impression that it would go away of itself, as it had done before. On being called on the morning of the 16th, at 4.30, I went, accompanied by my student, R. C. Irving, and Drs. D. F. Leavit and P. W. Cremin. A conference was held, and it was resolved that she be again put under the influence of chloroform, and another effort be made to reduce it, which was done at once, and after a fair trial by each of the physicians present without success, hope of relief through such means was abandoned. I then suggested that before we resorted to the knife an effort might be made to reduce the hernia by passing the hand through the rectum into the colon, and endeavoring through its walls to produce traction on the involved intestine sufficient to disengage it. This was approved of, and I accordingly did so and succeeded.

The steps of the operation were as follows: The patient being fully under the influence of chloroform, was placed on her chest and knees, and supported in that position; I next introduced my fingers into the anus, and passed my hand by gentle pressure up into the colon. I had some difficulty in following the intestine over the promontory of the sacrum, but when my hand had passed this point it was very free. I could feel the engorged intestine plainly, and could make traction on it with my fingers, and did carefully, fearing that I might rend it. My manipulations consisted, chiefly, in gently rubbing my finger along the intestine from the inner surface of the ring, and using external taxis with my other hand at the same time.

The desired result was accomplished in about ten or fifteen minutes with comparative ease. There was no omentum involved, as I had been led to think by the boggy feeling of the coats of the strangulated intestine by serous infiltration.

After the reduction I bandaged the patient around the bowels tightly, and put over the hernial opening a firm compress made of a bladder containing ice, covered with a napkin, and gave her a hypodermic injection of ℥v. of Magendie's solution. Her vomiting from this time ceased. She complained very much of pain in the lower part of her bowels for the first twenty-four hours, and a smarting pain in the anus; could not pass her urine except by catheter, which was attributed to her not being able to sit up on a commode.

June 17.—Very comfortable, her bowels had moved freely, and all nausea had passed away.

June 21.—Recovery is quite complete; has only slight soreness in and around the anus. Bowels move every day naturally. Diet prescribed throughout was liquid, chiefly milk, beef-tea, and gruel.

There was nothing remarkable in the treatment of the case other than what has been mentioned. As to the relative merits of this method of reducing a strangulated hernia I can say but little. It might not succeed so well in another case, but it is reasonable to suppose it would, if carefully done. This patient was by no means a favorable one on whom to make the first trial.

155 E. 51st St., New York, June 21, 1875.

A LETTER WRITTEN BY HARVEY has been discovered by Dr. J. H. Aveling among the Clarendon papers, and is, if the memorandum at the back of Dr. Ward's letter be excepted, the only letter in Harvey's own hand known to exist. The letter is to appear in the July number of *The Obstetrical Journal*.

ABSCESS OF THE LIVER AND ITS TREATMENT.

REVIEW OF A CASE REPORTED BY DR. SAYRE IN THE "AMERICAN MEDICAL WEEKLY" OF JUNE 12.

By WILLIAM CARSON, M.D.,

ONE OF THE PHYSICIANS TO THE CINCINNATI HOSPITAL AND THE GOOD SAMARITAN HOSPITAL.

THERE are some points of great importance besides the personal one in the case of the illustrious patient detailed, as our caption indicates, by Dr. Sayre, of New York.

We assume the correctness of the diagnosis. We believe General B. to have had abscess of the liver.

The pressing question which presents itself is: Was the plan of treatment proposed and executed by the distinguished gentlemen who participated in the consultation the proper one? This question we propose to examine from several points of view, with all due respect to the parties concerned.

Experience shows that the discharge of an hepatic abscess, through the lungs, is the safest one for the patient. Waring,* out of 300 cases collected and analyzed by himself, reports 25 which recovered:

By the abscess opening into and discharging through the bronchi.....	10
Opening into the colon.....	7
“ “ “ and another into the lungs.....	1
“ “ abdominal cavity.....	3
“ “ kidney.....	2
By spontaneous absorption (?).....	2
	—
	25

Thus of 25 cases of recovery by six different routes of discharge, ten, or nearly one-half, were cases of discharge through the lungs.

Analysis of Rouis' cases by Frerichs † shows 39 cases of recovery:

Where the abscess had burst through the abdominal or thoracic wall.....	17
[Three in last right intercostal space, 13 in epigastric region, below the sternum, and 1 at the umbilicus.]	
Where the abscess opened into the bronchi.....	15
“ “ “ stomach.....	3
“ “ “ transverse colon.....	4

I have 49 cases, all but two of which are unpublished ones, and the great majority of which occurred in the Ohio Valley. Out of these—

Recoveries have been.....	10
Through the bronchi.....	5
“ “ abdominal walls.....	3
“ “ lumbar region.....	2
The total number of recoveries in the three tables is 74.	
Those discharging through the lungs.....	30
“ “ “ abdominal walls... ..	17
“ “ “ colon.....	11

The duration of Rouis' cases of recovery was:

Where the abscess burst through the thoracic or abdominal walls.....	140 days.
Through the bronchi.....	115 “
“ “ colon.....	140 “
“ “ stomach.....	180 “

Thus the duration of the disease in cases of recovery was 25 days less in the cases where the discharge took

place through the bronchi than in those discharging through the thoracic or abdominal walls, or through the colon, and 65 days less than those discharging through the stomach.

This analysis of cases proves that the safest transit of matter is obtained through the lungs, and that the shortest duration of the disease is observed in those cases thus discharging. The presumption was thus, from recorded experience, in favor of non-interference in the case operated upon by Dr. Sayre, with the consent of his colleagues in the consultation, Drs. Desha, Gross, and Blackburn.

We come, then, to the circumstances of the individual case.

The important facts and basis of the diagnosis, as detailed by Dr. Sayre, are comprised in the following extracts from his article:

“We met at 4 P.M.—Desha, Gross, Blackburn, and myself. After a full history from Desha of his case (General B.'s), for the past three months, and from himself of his previous condition, we made a very careful physical examination of his whole body—first by Dr. Gross and then by myself. He was very much emaciated and anæmic, in fact almost bloodless. The feet were very slightly œdematous, which might easily occur from his position (upright) in his anæmic state. There was no effusion in the abdomen; the chest was perfectly resonant and normal *all over the left side*. The same condition in right side, in its *upper two-thirds*. The lower portion of right side dull all round; intercostal spaces rounded out, and on measurement from median line to centre of spine, one inch and seven-eighths larger than opposite. In the upright posture, percussion gave dullness at a fixed line, which was marked with a pencil. [In almost every instance when I put the pencil on him, he remarked, ‘That’s it,’ ‘There you are,’ ‘You are right on the line,’ or some similar observation.] On laying him over forward the line of dullness changed position, extending higher in front and more resonant behind and below the line of dullness, when upright, showing that the dullness was from a fluid, and not from consolidation. On slaking him, *no succussion* was obtained, leading us to believe that the fluid was not in the pleural cavity, but deeper seated. Our diagnosis was probably (original) cirrhosis of the liver, subsequent inflammation of lower lobe of right lung, adhesions of liver, diaphragm, and lung, with abscess of liver and lung, which had found an outlet through the bronchi. Death was inevitable, and his only hope of prolonging life, or being comfortable, was by making an outlet below, to save him the effort of coughing up this immense amount of offensive viscid, tarry pus, blood, and mucus, and which Dr. Desha stated had often threatened to suffocate him. After carefully considering the whole case, we all agreed that this was the only chance to make him comfortable, and if successful might prolong his life, but never cure him.”

The facts included in this paragraph are: that General B. was in a feeble and anæmic state; that his constitutional condition was a bad one; that the condition of the viscera, except the liver and right lung, was such that they had no causative connection with his prostration; that there was originally cirrhotic inflammation of the liver, which had become suppurative, with final discharge of pus through the bronchi. Possibly his œdematous feet indicated something more than anæmia—damaged kidneys.

There are facts of some importance, which are implied, but not stated explicitly. They are: that these events of violent paroxysms of coughing and quickly succeeding expectoration, or eruptions of matter, had

* An Inquiry into some Points connected with Abscess of the Liver, p. 195.
† Clinical Treatise on Diseases of the Liver, p. 133.

been transpiring for several months; that they had been occurring without disturbing those local relations of the diseased organs which secured the safest method of evacuation of the abscess until the operation; and that during their occurrence, and at the time of the operation, there was such a residuum of vigor as enabled him to endure a rigid examination by Drs. Gross and Sayre, in the upright and other positions, give his own account of his case, and converse in such a way as to call forth the admiration of the gentlemen present. Other evidences of his condition will be found in the account of the operation, such as dressing himself and meeting them in his parlor, and his participation of a very good meal, etc., etc.

We come now more particularly to the diseased tissues and organs, the exact condition of which it was highly important to realize. It was advisable that there should be the clearest apprehension of what existed before the methods of relief was selected, or the effect of any attempt could be anticipated. Hence a physical examination was a matter of the utmost importance. One was made by each of the consultants. The facts of them, as given, are scanty and unsatisfactory, and not correctly interpreted. It was not correct to infer that fluid did not exist in the pleural cavity because the physical sign of succussion was not developed. Succussion may fail, whether much or little fluid exist in the pleura. It would seem that the other fact of the physical examination—that of the mobility of the fluid or the line of dullness determined by it—was exaggerated or overestimated. Confinement of a fluid or pus within the walls of an hepatic abscess, below the diaphragm, which must have been more thickened than usual, and to which a lung more or less condensed was adherent above, would not be apt to allow such variations in percussion sound at the surface of the thoracic wall as to make the physical sign thus developed a reliable guide for a serious operation. This view is confirmed by a comparison of the statements in regard to the first examination and those in regard to the operation. After a copious eruption of "one quart, one pint and a half" of blood, pus, etc., in five hours preceding the first examination, it is stated there was enough remaining to allow the demonstration of the mobile line of dullness on the thoracic wall, while after the tapping, immediately preceding which there had been an eruption of only one and a half pints, the sac could not be reached by any instrument in possession of the operators. Where, too, was the consolidated and adherent lung that must have been more or less involved in this aggregation of inflammatory products, adhesive and inflammatory, that it gave no sign?

The physical examination, then, did not determine the precise locality, extent, or distance of the abscess from the thoracic or abdominal walls—its precise topographical relations were not understood or defined at the time it was proposed to divert its contents by surgical interference.

To the operation itself we next refer. We think we may state that there was no warrant for any interference, whether we consider the more purely local conditions, the vital resistance of the patient, who had sustained the shocks of his severe disease to the extent indicated by incidental facts mentioned in the report, or the general experience of the profession, as our figures show it to be, that discharge through the lung is the most favorable mode of escape.

We quote: "When I arrived I found him dressed and in the parlor, instead of being in bed ready for the operation." "After coughing up a little *over a pint and a half*, he seemed *comfortable*; was put to

bed, chloroform administered, and I made an incision one and three-fourths inches in length, along the upper border of the eighth or ninth rib into the pleural cavity; no pus escaped, proving our diagnosis, that the fluid was not in the pleural cavity, was correct. The lung receded before the atmospheric pressure, and the finger passed into the cavity could feel the walls of the diaphragm and adherent lung, but we had no trocar long enough to reach it, and it was decided to wait until the abscess again filled, which would bring its walls near the external opening, and then puncture with the trocar or aspirator."

The object of surgical interference, as stated, was to divert the escaping pus through another channel, so that the danger of suffocation might be avoided. The dependent point was not at the line of the eighth or ninth rib; ordinarily it would be found, probably, somewhere in the epigastric or right hypochondriac regions. Yet there would have been no justification in puncturing these, because there was no physical sign indicating the close proximity of pus, nor was there evidence of the close adhesion of the hepatic substance and abdominal walls, which diminishes or avoids the risk of peritoneal injury and its dangerous consequences. Opening the pleural cavity, which had before been diagnosed as free from fluid, would not secure a successful diversion. Bringing the pus into the pleura, whether through the diaphragm, or lung, or both (it is not clear which it was the intention to do), would add another immense inflammatory and suppurating surface to that already existing in the cavity of the abscess; would be substituting a suppurating surface of immense reproductive capacity for the comparatively non-suppurating tissues of the lung and bronchi; would produce (as it did) collapse of the lung, thus withdrawing the elastic and yet firm support of that organ from the safely-established route of exit, and thus curtailing the resources of an already much crippled patient; would keep up an irritating cough, and would fail of its main and immediate purpose, that of keeping up a free discharge of the pus, because it would (as it did) strike a level above that of the abscess.

The operative procedure was not properly guarded. An opening of an inch and seven-eighths into a cavity like the pleura or abdomen should not be made except upon the most unequivocal evidence; it should have been in this case preceded by exploration with a hypodermic syringe, which can be found everywhere, or the aspirator. These precautions taken to determine the locality of the pus, might have failed, but they would also have prevented the greater failure of making this free incision, and then finding the "objective point" beyond the reach of any instrument which the operators had provided.

If there was in this case a peculiar personal interest, there was and is also a more than individual interest. Abscess of the liver is not an uncommon disease in this country, and the principles and practice involved are therefore matters of general concern. Representative men were responsible for the plan pursued in this case. It is desirable to know whether the precedent is a safe one.

THE NASHVILLE JOURNAL OF MEDICINE AND SURGERY is to be edited by William T. Briggs, M.D., and Thomas O. Summers, jr., M.D. The former is professor of the principles and practice of surgery, and the latter, professor of anatomy and histology in the medical department of the University of Nashville and Vanderbilt University.

FATAL POISONING BY OIL OF CROTON.

By ROBERT M. DENIG, M.D.,

COLUMBUS, OHIO.

On the 2d of May last, Richard Connett, aged 26 years, a strong, healthy man, took by mistake one-third of a mixture containing—

Oleii croton tig. ʒ ij.
Ol. Perebint. ʒ ij.

Complained immediately of a feeling of intense burning in the gastro-intestinal tract, followed in fifteen minutes by copious vomiting. That the matter vomited contained part of the oil was evident from the circumstance that its accidental contact with the person of one of the attendants occasioned marked irritation.

Dejections followed in twenty minutes after mixture was swallowed, and both vomiting and purging continued at frequent intervals until death occurred, which took place at 7.30 P.M. of the same day. Meantime prostration was extreme, resembling collapse of malignant cholera. The discharges, though involuntary, were attended with great suffering. The sense of thirst was very great, and frequent potions of cold water were swallowed until within fifteen minutes of death. The mental faculties were unobscured, though for three hours before death his vision was so much affected that he was unable to recognize acquaintances. Two hours after swallowing the poison a hypodermic injection of morphine was administered, with the apparent effect of mitigating his sufferings. No other treatment was resorted to.

Post-mortem appearances 18 hours after death: Rigor mortis strongly developed. Ecchymosis over depending portions well marked. Pupils dilated. Congestion or hyperæmia of vessels of intestines, as exhibited by their arborescent appearance through corresponding peritoneum. Mesenteric glands were in a state of chronic enlargement or hypertrophy.

Gastro-intestinal mucous membrane inflamed, as noted by diffuse pink redness throughout, and patches of blood extravasation in the fundus of stomach. Solitary glands of small intestines were marked by pearly appearance; nothing unusual about Peyer's plates. Bladder contained a small quantity of urine; was contracted.

Liver, kidneys, and spleen normal. Lungs in a state of hypostatic congestion. Right side of heart contained a large, firm *ante-mortem* clot. Left ventricle empty; left auricle half-filled with semi-fluid blood. Apart from the heart-clot, which was nearly pure fibrin, and almost entirely free from red globules, there were no other symptoms of sufficient gravity to account for death.

The above case is interesting from the fact that so few fatal cases of poisoning resulting from the administration of this substance are recorded. The person who fell a victim in this instance was but triflingly indisposed, and was in his usual good health the day before his death.

There was no disease present to either complicate the symptoms or obscure the post-mortem revelations. How much the turpentine had to do with intensifying the effects we are unable to say. We believe it is sometimes added to facilitate the rubefacient qualities of the oil of croton. The physician in attendance prescribed two ounces of castor-oil and two drachms of turpentine. The prescription was written in English, with no directions as to whether it was for internal or external use, a verbal order having been left with the patient to take one-third of the mixture. The drug-

gist, in putting up the prescription, mistook the word *castor* for *croton*, consequently the man took about two-thirds of an ounce of *oil of croton*, and the symptoms which followed, as well as the post-mortem appearances, may justly be set down as due to the poisonous effects of the medicine ingested.

In the case reported by Dr. Ellis, of Ashland, Wis., in the *Am. Jour. Med. Sciences* for April, 1874, a little less than two drachms were given in a glass of whiskey, to one who was an habitual drunkard, and intoxicated at the time.

The man vomited but did not purge, and was found next morning not far from the saloon from which he had been ejected, dead,—cold and stiff. The post-mortem, made at 12 M., revealed: Brain, heart, and lungs in healthy condition; no abrasion or discoloration of mucous membrane of the mouth. On opening the cavity of the abdomen the external coat of stomach, duodenum, and several portions of small intestine were found to be of an intensely dark-red color, showing severe inflammation; but no effusion of coagulable lymph was seen. The mucous lining of the stomach, duodenum, and small intestines, corresponding to the external discoloration, was much inflamed, almost disorganized. In the stomach was about half a pint of thin chyme, on the surface of which floated a film of oil having the odor, etc., of croton oil.

It is difficult in this case, as the gentleman who reports the case remarks, to separate the effects of constant alcoholic stimulation from those due to croton oil. It is singular also that no signs of purging were discovered.

In the *Annales d'Hygiene*, tome xxxv., 1871, a fatal case is reported in which a man in an advanced stage of typhoid fever drank through mistake two and a half drachms of croton oil.

Three-quarters of an hour afterward alarming symptoms intervened: skin cold, covered with cold perspiration; pulse almost imperceptible; heart-sounds scarcely audible; respiration very much embarrassed; lips, eyelids, fingers and hands blue, like algid stage of cholera; pupils medium, but insensible to light; abdomen extremely sensitive to touch; fruitless attempts at vomiting, rejecting only some glairy mucus slightly colored with the oil. One hour and a half after the ingestion of the poison involuntary alvine discharges commenced. All these symptoms rapidly intensified, and in four hours after taking the dose death occurred, accompanied with some of the symptoms of asphyxia.

Autopsy revealed only slight softening of the mucous membrane of the stomach and bowels, with numerous ulcers characteristic of typhoid fever.

The same difficulty presents itself here as in the case mentioned above; viz., that of separating the pathological changes due to the fever from those occasioned by the irritating effect of the oil of croton. In the same volume of the *Annales* four non-fatal cases are given, in three of which large quantities were taken.

A chemist, 43 years old, took by mistake for cod-liver oil one ounce and a half of croton oil. Experienced almost immediately burning sensation in the throat and stomach, followed by violent vomiting and purging, the patient asserting that his dejections amounted to one hundred in number before entering the hospital. When brought there he presented the following symptoms: skin cold; face, hands, and toes slightly evanosed; pupils dilated; senses intact; felt cold; pulse feeble, respiration painful, 12 per minute; abdomen tympanitic, extremely sensitive, persistent vomiting and purging. Treatment: emulsions of cherry-laurel water; milk and almond emulsion for

drink; cold to head; injections of ice-water, with opiates. Recovered.

A little girl, six years old, took by mistake three grammes (45 grs.) of croton oil. She complained of an acrid feeling in the throat when it was swallowed, and in a few minutes had severe pain in the stomach, followed by frequent vomiting and purging, lasting three-quarters of an hour, when she fell asleep. On awakening she asked for food, took some broth, and experienced no other unpleasant effects.

HOW DOES CROTON OIL OCCASION DEATH?

In the case here first reported it was evidently due directly to the heart-clot; this, as formerly stated, was fibrous throughout, and firmly embedded among the cordæ tendinæ, etc., of the cavity of the ventricle. Other than this no post-mortem revelations were present of sufficient gravity to account for death. It cannot be from intestinal inflammation, as death occurs too suddenly to be due to this cause; nor to the exhausting effects of the purging, as this is not always present—as in Ellis's case. The symptoms observed in fatal cases of poisoning from this substance, and even in those not fatal, resemble strikingly those which Tardieu classes under *hyposténisants*; and in which class he places arsenic, phosphorus, salts of copper, salts of mercury, nitre, and digitalis. The following is his description of acute arsenical poisoning: Acrid burning in the throat; nausea, with repeated vomiting; ardent thirst, drink immediately exciting renewed vomiting; pain in the epigastrium increased by pressure; sometimes violent pain in the head; alteration of the features; coldness of the extremities; tendency to syncope; pulse scarcely perceptible; respiration much embarrassed; frequent alvine discharges, sometimes involuntary, accompany or succeed the vomiting; countenance pale, then cyanosed; vital forces rapidly fail; surface becomes cold, and death intervenes in from five to twenty hours from the first signs of the poisoning. No more complete description could be given of the symptoms following the ingestion of a poisonous dose of oil of croton.

It seems to us obvious that the fatal result is due to the depressing influence of the poison on the functions of organic life through the nervous system, and not due *mainly* to the vomiting and purging;—that it kills by entering the circulation, and not by its irritant local effects.

Progress of Medical Science.

THE DIAGNOSIS OF OVARIAN CYSTS AND THE INDICATIONS FOR THEIR TREATMENT.—Dr. Rheinstaedter, of Cologne, thus reduces to formulæ his views of the indications that can be drawn from the fluid obtained by puncture from suspected tumors. 1. The presence of paralbumen does not at all prove the existence of a hydrovarium. 2. From its absence we cannot argue with certainty the non-existence of cystic disease of the ovary. 3. There is great probability of a hydrovarium, if we find paralbumen abundant, with a viscid condition of the fluid, like barley-water, and with an abundant deposit of cellular detritus, and large round cells that are swollen or undergoing fatty degeneration. 4. The presence of well-formed, nucleated cells of cylindrical epithelium collected in groups or rows speaks positively for hydrovarium, especially when this microscopic investigation agrees with the gross appearances and the chemical constitution of the fluid. Dr.

Rheinstaedter lays down the following as the *indications* for treatment. The danger of the operation always stands in direct relation to the danger of the disease itself, and this sometimes gives little trouble for many years, and is even sometimes spontaneously cured. A woman then, with a moderate large ovarian cyst which is stationary, and occasions no special difficulty, should not be operated on unless she urgently desires it. An expectant treatment should be adopted, including general hygienic measures, the avoidance of all causes of sexual irritation or excitement, the wearing of a body bandage, and careful attention to any complications. The patient should not marry, because of the danger of pregnancy as a complication. If, however, the cysts grow rapidly, so as to interfere with the functions of the body, and occasion loss of strength and severe neuralgic pain, extirpation is indicated. There are also certain circumstances, such as hemorrhages into the cyst threatening life, that call for immediate extirpation, as do also suppuration, or ulceration of the cyst, perforation followed by peritonitis, or symptoms of incarceration of the bowel in pseudo-membranous bands. Puncture, either with or without the subsequent injection of iodine, is now generally rejected as a radical mode of treatment. It is uncertain, because there may be more than one cyst; it may cause circumscribed peritonitis, and adhesions which will complicate an ovariectomy when it has to be performed. Puncture with drainage from the abdominal walls is generally rejected, because the sac cannot be completely emptied of its ichorous contents. Puncture through the vagina, on the other hand, is regarded favorably in case of small cysts firmly attached in the pelvis, and it can be combined with drainage and the washing out of the cyst with medicated fluids, a mode of treatment which may be adopted even in the case of large cysts, and they can be reached in this way, if ovariectomy is refused. We should endeavor to persuade the patient to the latter, however. For purposes of diagnosis, however, puncture can, and should be employed in almost all cases, either through the vagina or abdomen, according to the accessibility of the tumor. Puncture may also serve as a palliative in cases where the tumor cannot be removed on account of adhesions, or where there is the complication of pregnancy occasioning pressure symptoms, where the internal organs require prompt relief. The contra-indications of ovariectomy are pointed out as above. It may, however, be indicated sometimes in pregnancy, when the symptoms due to pressure are urgent and cannot be relieved by puncture, or where there has occurred rupture of the cysts. In such cases, it is preferable to either artificial abortion, or artificial premature delivery. Ovariectomy is also contra-indicated in the presence of serious disease of internal organs which threatens to end fatally; also in cystic carcinoma.—*Berl. Klin. Woch.*, May 31, 1875.

MEDICAL ASSOCIATIONS IN AUSTRALIA.—*The Australian Medical Journal* estimates that there are about 1,200 practitioners in the Australian colonies, including Tasmania, of whom something less than 500 are in Victoria, rather more than 400 in New South Wales, about 150 in South Australia, probably 100 in Queensland, and about 60 in Tasmania. In Melbourne and Adelaide there are medical societies, and there used to be one in Sidney. The Medical Society of Victoria numbers about 120 members, and this is by far the largest number of the 1,200 who have ever associated themselves together. The question of organizing an Australian Association is being agitated.

THE SANITARY CONDITION OF RURAL RETREATS.

THE sanitary condition of rural retreats is a subject in which a fresh interest is developed every time the season approaches when country board is in demand. We are willing to admit that a large number of the country hotels and farm-houses which are opened to the public patronage, answer the intention of their proprietors in being health resorts; but that a fair proportion of these places are abominations in a sanitary point of view, is beyond a doubt.

There are a great many circumstances which conspire to make any country place unhealthy, some of which are beyond control, but of these it does not concern us at present to speak. We only wish to refer in this connection to the existence of those conditions which are quite general and prevalent, but which are at the same time preventable.

No two elements are deserving of more consideration in the discussion of this part of the subject than house-drainage and the character of the drinking-water. Indeed, one of these conditions depends so much upon the other, that they may be almost treated together. Not long ago we were called upon to notice the sickness and death of several boarders in a fashionable country hotel, caused by the admixture of the contents of a foul cistern with the drinking-water. From the prominence of the establishment, and the social position of the victims, the affair attained a wide publicity, and thoroughly awakened popular attention to what at first seemed to be a trivial matter. To a superficial observer this would doubtless appear as an isolated instance of its sort, but to such as are acquainted with the sanitary surroundings of the ordinary farm-house the case is altogether different. The same condition of things which culminated in the death of the patrons of this first-class hotel exists to a greater or less degree in many of the country boarding-houses which

are opened annually for the reception of metropolitan health-seekers.

Not only is little attention paid to drainage in the ordinary acceptance of the term, but we have other circumstances and conditions to take into account which may be considered somewhat peculiar to rural habitations. In the first place, the drinking-water is supplied by a well, which for convenience is in close proximity to the house; and in the second place, and for a like convenience, the privy is not very far off. Again, the barn-yard, which is likely to be near the house, is another element of soil contamination, the deleterious influences of which upon health can hardly be overestimated. It is quite natural to suppose that with all these influences at work, it is the exception rather than the rule for the well-water to remain absolutely pure.

No one doubts the bad influences of impure drinking-water upon health, and many a practitioner in the rural districts has been able to trace attacks of severe and dangerous illness to this source alone. It may be a pertinent question in this connection to inquire how much of the diarrhoea and other intestinal troubles which are usually charged to a change of drinking-water may in reality be due to leakage of sewage into the wells. A great many curious facts are related in support of such a supposition, and while they may not be absolutely proven, are quite suggestive to the inquiring mind. It is well known that many of the low forms of fever are also due to foul well-water, the relation of cause and effect being established beyond a reasonable doubt. Quite recently an elaborate paper on this subject was read at a meeting of the Public Health Association, in which some very curious and instructive facts were related bearing upon this point. Almost every practitioner has been able to corroborate to a greater or less extent all of these facts by his experience—has been enabled to note the modifying influences which these conditions of bad drainage and its attendant evils have upon the course of epidemics in a particular district, or particular household. We need not, however, multiply examples of this sort to bolster established facts.

As the causes of the unsanitary condition of these country boarding-places are entirely within our control, it becomes us to throw the influence of our professional opinion in the proper direction. Those medical gentlemen who are practising in districts in which the ordinary sanitary precautions are neglected, should do their utmost to educate their patrons to appreciate the necessity of a conscientious attention to such matters; while those who are in the habit of advising metropolitans to go to the country for the summer, should put them on their guard against the possible dangers that may await them in the many so-called healthy localities.

Many of the evils of defective drainage in rural districts are multiplied in proportion to the number of people who may be congregated at one place. Par-

ticularly is this the case with the so-called religious gatherings, which partake more of the character of pilgrimages than of healthful recreation. It has lately become the custom for large numbers to congregate on grounds purchased for the purpose, and hold the so-called camp-meetings. Not only are those who attend very much crowded and provided with insufficient shelter, but in the majority of instances little or no provision is made for drainage; and, under ordinary circumstances, it is only a question of time to insure the outbreak of some of the more intractable and malignant diseases which have been the scourge of armies in times when military hygiene was little understood and less practised. Already some of the managers of the larger camping-grounds are deploring the fact that the necessary precautions have not been taken to provide adequate sewerage, and already there is an anxiety for the possible evils which may grow out of any continued neglect of suitable preventive measures. These meetings should be looked upon from a sanitary point of view in the same light as an army in camp, and should be treated as such. The managers who may choose to ignore their duty in this respect assume an unwarrantable amount of responsibility, and in the face of well-known sanitary laws can hardly be held to too strict an accountability.

A NEW RECEPTION HOSPITAL.

OWING to the present insecure condition of the Park Hospital of this city, the governors of the New York Hospital have undertaken to supply its place, so that the lower portions of the city may be provided with a station for relief in case of emergencies. The Commissioners of the Sinking Fund of the city have turned over to them the building, No. 160 Chambers Street, formerly used as a police station, and its doors were thrown open on the 5th inst. for hospital purposes. It is called the "House of Relief of the Society of the New York Hospital," and it is understood that only such cases will be received as need immediate relief, or cannot well be removed to more distant points. As soon as the patients can bear transportation they will at once be removed. About twenty patients can be accommodated. The equipments, when finished, will be complete, both for the care and transportation of patients. The management is in the hands of a medical superintendent, who is also chief of the resident staff, and has two assistants. We learn that the service has already been quite active.

BRITISH MEDICAL ASSOCIATION.—The forty-third annual meeting of this association will be held at Edinburgh, commencing August 3d, and continuing four days. Sir Robert Christison is the president elect. The address on medicine will be given by James Warburton Begbie, the address on surgery by James Spence, and the address on physiology by William Rutherford. A large number of interesting papers have already been offered to the secretaries of the different sections.

Reports of Hospitals.

BELLEVUE HOSPITAL.

REPORTS OF PRACTICE AND PECULIARITIES IN TREATMENT.

COLOR OF THE BLOOD IN LEUCOCYTHEMIA.

It has been insisted upon by some observers that the blood in this affection has a *milky*-white color, easily recognized when a drop is placed on a microscopical slide. A drop of blood, taken from the patient by whose bedside we stood, presented the characteristic milk-white color, but unfortunately no undue proportion of white blood-globules was discovered, and the reason was that a single drop of blood taken from any person, and placed on a glass cover will present *the same appearance*.

DISEASE OF THE ELBOW-JOINT.

The interest in the case turned upon the decision of the question whether it was one of synovitis or of acute articular rheumatism. There was swelling, heat, pain; and the pain was relieved by compression rather than by extension; there was no very marked constitutional disturbance; it was his first attack, and there was no history of injury. The trouble showed no tendency to disseminate itself, and there were excessively tender points over the sides of the joint, but no fluctuation. The possibility of only one joint becoming affected with rheumatism was acknowledged, but it was thought to be impossible to determine in all cases which disease is present, especially in the earlier part of its course. The joint was leeched and fomented.

ACUTE ARTICULAR RHEUMATISM — PERICARDITIS — PLEURISY.

Pericarditis is so common in the course of rheumatism that it may with propriety be regarded as a part of the affection, but the occurrence of pleurisy with the disease is rather infrequent. The patient, *æt.* 19 years, was the subject of both diseases secondary to the articular affection, and both had been developed since his admission to the hospital. The amount of serum in the pericardial sac was considerable; the pleurisy was upon the left side, and the amount of effusion was not very great.

Alkalies and quinine, counter-irritation over the heart, and rest in bed were the leading elements of the treatment.

STEADY DECREASE IN THE SECRETION FROM THE KIDNEYS UNTIL THE QUANTITY OF URINE PASSED DAILY HAD REACHED EIGHT OUNCES.

A female patient who had phthisis, and also very moderate symptoms of Bright's disease, on the first day of the month passed eighteen ounces of urine; but since that time the quantity had been on the decrease, and had decreased steadily while diuretics were being administered, until the 18th day of the month she passed only eight ounces. The woman had not suffered any inconvenience whatever on account of this state of affairs.

VOMITING IN BRIGHT'S DISEASE.

In a few cases the use of electricity has seemed to have a good effect in controlling this symptom. It would check a vomiting attack, but the emesis would return, perhaps in a few hours, and the question arose, whether it was any more efficient for this purpose than any agent capable of producing a new

impression upon the patient. One pole (immaterial which) was placed over the epigastrium, and the other over the *vertebra prominens*, and then carried up and down the spine.

ACUTE PLEURISY—RAPIDITY OF EFFUSION.

The point of interest in this case was the amount and rapidity with which the effusion had taken place.

A male patient, forty-five years of age, was in perfect health up to three weeks ago, when he was seized with a chill, which was followed by considerable fever, and soon after by shortness of breath.

The shortness of breath quickly became the leading symptom, and was soon accompanied by pain, extending over the left side of chest and upwards over the left side of the head, which was so severe that he was unable to lie down. When he was able to assume the horizontal posture he could lie only upon the left side. Upon physical examination it was found that absolute flatness extended from the bottom of the left pleural cavity up to the clavicle, and that vocal fremitus and vesicular respiration were entirely absent.

So far as the products of inflammation were concerned, they were evidently those found in subacute, or pleurisy with effusion, but the clinical history was essentially different. It was regarded as one of those cases of pleurisy—occasionally seen—in which serous effusion predominates, ordinarily increases very rapidly, and one element of danger in them is the development of syncope by pressure of the fluid upon the heart, for they occur chiefly, if not always, upon the left side.

Such syncope may prove fatal, and that fact gives rise to an important item in treatment, namely: relieve the tension at once by removing a portion of the fluid. In this case a portion of the fluid had been removed, and the remainder was passing away through the action of the absorbents, which were being stimulated by maintaining nutrition at the highest point possible. In case that the fluid did not disappear with considerable rapidity, paracentesis was to be performed at the end of one week.

DIFFICULT DIAGNOSIS.

A servant-girl, *æt.* thirty, and perfectly well up to five months ago, began to suffer from shortness of breath, which was followed by "heavy dry cough" that continued a few days, and then pain extending over the left mammary and into the axillary region. She recovered from the first attack and resumed her work, but was able to continue it only for two or three weeks, and thus she has gone on, at one time better, at another worse, sometimes able to work, at other times not, and was each time compelled to abandon her labor on account of the pain in the side and shortness of breath. Fever accompanied some of the attacks, but was not constant. She has lost considerable flesh, and the cough at no time has been attended with expectoration, nor has she ever had hemoptysis. She has been unable to work during the last month, and came into the hospital to obtain relief, and this completes the history of the case.

Upon physical examination of the chest there were found a pericardial friction-sound, retraction, and loss of expansion, feeble vocal fremitus, flatness, broncho-vesicular respiration feeble but distinct, and pleuritic friction-sounds over the lower portion of the left side posteriorly, with bronchial respiration anteriorly at the upper portion, and vocal resonance intensified from the top of the chest downward, though less distinct at the lower portion of the chest than at the upper, but no râles. Upon the right side were found, posteriorly below the scapula, absence of vocal fremitus

and voice-sounds, flatness, and loss of both respiratory murmur and expansion; while at the upper portion there was exaggerated respiration. Over the pericardial region there was complete absence of respiratory murmur. What had given rise to the pericarditis, and how were the physical signs relating to the lungs and pleura to be explained? It was believed that five months ago the patient had an attack of pleurisy affecting the left side, which may have been productive of simple plastic material or serum in addition. Following this a gradual consolidation of the lung had taken place as the result of an interstitial pneumonia, excited by the pleurisy. The inflammation extended over that portion of the pleura covering the pericardium, adhesions occurred, and pericarditis was developed in consequence. There was fluid in the right pleural cavity, and it seemed probable that it was a recent accumulation.

REMITTENT FEVER.

The point in the case to which special reference was made was with regard to the administration of quinine.

A male patient, twenty-eight years of age, had an attack of chills and fever eight months ago, from which he recovered after taking a few doses of quinine. He had been exposed more or less to malarial influences since that time, and his present sickness was of fifteen days duration. It was ushered in by a chilly feeling, but not by distinct chills, extending over two or three days; thirst, malaria, and pains all over the body; and these symptoms continued ten days, when he came into the hospital. Since admission his temperature has ranged from 99° F. to 101¼° F. with evening exacerbations; his pulse rose to 96, and a yellowish coating was upon the tongue, but there were no sordes upon the teeth, no diarrhoea, no tenderness in the right iliac fossa, and no eruption. He had had some headache and vomiting. There was considerable enlargement of the liver and spleen, and pressure over the former gave rise to considerable pain. The case was regarded as one of mild remittent fever, which was plodding its way along now as a continued fever, and it was to the manner of administering quinine in such cases that especially attention was drawn. It was to wait until the temperature goes down, watching it carefully, perhaps making a record every four hours, and when it falls, as certainly it will, administer a large dose of quinine, say twenty or thirty grains, and that may be repeated in eight or twelve hours. In these cases the thermometer is the most intelligent guide in the use of the remedy, for one single large dose given at the time the temperature falls is far more serviceable than the continued administration at stated intervals of smaller doses.

PLEURO-PNEUMONIA.

The point of interest in this case was the accession of the pneumonia after the pleurisy had existed several days, for it was upon this fact that the above diagnosis was made. A man, about thirty years of age, and of good habits, was perfectly well up to twelve days ago, when, in the night, he awoke with a severe pain in his right side, just beneath the nipple. The pain passed away before morning and did not trouble him again until the next night; then it returned, but passed away the second time. On the third night it returned; was so severe the following morning that he was unable to lie down, and was accompanied by fever and vomiting. He remained in about this condition until the fourth day, when he was admitted to the hospital.

He had not had a chill, but an irritating cough had

been present from the beginning of the attack, and was attended with an expectoration of only a small amount of whitish material. When admitted his temperature was $100\frac{1}{2}^{\circ}$ F., and remained at about that point until three days ago, when he had a chill, and his temperature went up to 103° and 104° F. The cough remained about the same, but was not accompanied by any "rusty" expectoration. His countenance was only moderately flushed; respiration was about normal, and the pulse was 100. Upon inspection, it was found that the right side moved but little when a full inspiration was taken, and palpation revealed the fact that vocal fremitus was almost entirely absent. Flatness upon percussion was detected over the lower portion of the right lung; anteriorly and posteriorly, and the line of flatness was not changed materially by changing the position of the patient. There was loss of respiratory murmur, but bronchial breathing and bronchophony were well marked just below the line of flatness, and the former could be traced nearly to the bottom of the pleural cavity. Fine crackling sounds were also heard at the end of inspiration.

Such cases as this are occasionally seen, and are usually rather perplexing. The points to be noted are:

1. The history, the flatness upon percussion, the early increase of temperature, the friction-sound, and the loss of vocal fremitus, all of which point to pleurisy.

2. The chill, the rise in temperature, the bronchial breathing, and bronchophony, pointing towards pneumonia.

3. Absence of the characteristic expectoration of pneumonia, with his age and previous condition. The fact that bronchial breathing was most intense just below the line of flatness, and could be heard nearly to the bottom of the pleural cavity, was regarded as straight evidence that consolidation of lung tissue was present. The prognosis made was, that probably a year would elapse before the lung would become completely free. Treatment: dry cups, carbonate of ammonia and quinine.

APOMORPHIA.

This remedy has been used in the hospital as an emetic in two cases.

It has been claimed that the "great promptness of its action, the freedom of its emesis from nausea, and its ease of administration recommend it for all cases in which simply a prompt emptying of the stomach is desired." It is used hypodermically in doses of $\frac{1}{2}$ to $\frac{1}{10}$ of a grain. Of these instances one was said to be a case of poisoning by arsenic, and the stomach had been washed out before admission to the hospital. A hypodermic injection containing $\frac{1}{2}$ of a grain of this remedy was administered, and the patient vomited in about eight or ten minutes. The solution used, however, had been prepared for some length of time.

The other case was one in which there had been rather too free indulgence in alcohol; but a freshly prepared solution of the remedy was used, and the same amount administered as in the other case emptied the stomach within two minutes.

PLUGGING THE POSTERIOR NARES.

This operation is one of the bugbears in surgery, therefore a simple method of performing it may be repeated without giving offence. It may not be anything new, but the ease with which it was performed in this case was certainly agreeable to the patient and pleasing to the surgeon. A small bougie having a bulbous extremity (a fine catheter may answer the same purpose) was introduced into the nostril to be plugged,

and carried along the floor until it could be seen emerging into the pharynx; this extremity was then seized with a pair of long forceps—which can usually be done without inconvenience to the patient—and brought forward through the mouth. A strong silken cord was then attached to it, and to the other extremity of the cord was fastened a pledget of lint. The bougie was then withdrawn from the nostril, and with it the string to which was attached the plug, and then this was drawn through the mouth, and quickly carried up behind the velum into the cavity for which it was designed. The operation gave the patient but little inconvenience, and the plug was to remain until the *natural secretion of the parts loosened it sufficiently to permit a spontaneous removal.*

METHOD OF APPLYING A TAMPON.

Take a piece of fine rubber cloth,—a piece of soft muslin or a pocket handkerchief will answer—oil it upon the outside, if you choose, and then, placing one or two fingers in the centre of it, letting the cloth hang over the hand, carry it into the vagina as far as desirable, or into whatever cavity you wish to tampon and can carry the finger. This can be done without giving the patient any more discomfort than does a digital examination.

Now we have a collapsed pouch-like cavity, which can be distended at the pleasure of the operator; may be filled without risk of injuring the soft parts; and without the tugging ordinarily experienced when a tampon is introduced without a speculum.

CARBUNCLE.

Sir Astley Cooper has said that carbuncle, occurring upon a person over seventy years of age, will prove fatal. Here was a man, however, who was seventy-seven years of age, who had had a large carbuncle upon his shoulder, but it was nearly healed, and the old man was hale and hearty. Quinine and iron, good food, cleanliness, simple cerate, and balsam of Peru, had made up the treatment.

PNEUMONIA.

The peculiarity of this case consisted in the presence of considerable bronchitis and pulmonary oedema in addition to the pneumonia. The patient was a man about thirty-five years of age, medium size, and very muscular. The lower lobe of the left lung was the part chiefly affected by the pneumonia; there was marked bronchophony, but no true bronchial breathing, and he had had the "rusty" expectoration. In addition there were subcrepitant and fine mucous râles all over the posterior portion of the chest, and he had expectorated considerable frothy material, mixed with blood. In this case and several others a single large dose of quinine had been given early, say thirty grains, to see what the effect would be upon the progress of the pneumonia. In a few cases it *seemed* as though the progress of the disease had been arrested. No positive conclusions, however, had been obtained.

A STATE BOARD OF HEALTH IN GEORGIA.—Through the exertions of Dr. J. G. Thomas, of Savannah, Ga., who was last year elected to the Legislature, a State Board of Health has been organized, of which Dr. Thomas is himself President, and Dr. V. H. Talliaferro, of Atlanta, Secretary. The Board consists of Drs. J. G. Thomas, Geo. F. Cooper, B. M. Cromwell, F. A. Stanford, C. B. Nottingham, H. H. Carlton, G. W. Holmes, J. P. Logan, and H. F. Campbell, with the Comptroller-General, Attorney-General, and Geologist of the State as ex-officio members.

Correspondence.

OPERATIONS FOR VESICO-VAGINAL FISTULA.

A LETTER FROM DR. BOZEMAN.

FROM a letter addressed to Dr. Jean F. Chauveau, of this city, we quote the following:—

In my last letter I told you also I would give you soon the result of my operations in Heidelberg. I was there with Prof. Simon about six weeks. He received me very kindly, and seemed glad of the opportunity to make a practical test of our respective operations, with the view of determining the range of their applicability. He performed from first to last four operations by his method, with the following results: three partial successes and one death.

The first case presented a good-sized fistula, which occupied the base of the bladder. Here the uterus was movable and could be easily drawn down for the operation, which is essential to the success of Prof. S.'s method in fistulas situated high up. About seven-eighths of the fistula was closed.

A second case was that of a woman upon whom he had performed kolpokleisis seven years before. The result of the first operation was cystitis, and the formation of a stone in the vagina above the seat of closure. This stone finally cut through the cicatrix, thus reopening the vagina. The patient's condition having become unendurable, she applied to Prof. S. the second time. The operation he performed had for its object the reclosure of the vagina, which I witnessed. It was kolpokleisis the second time. On the tenth day the patient died. Autopsy: Fistula, or rather the vagina, not closed; the denuded edges throughout having separated. Both kidneys extensively diseased, and a calculus in the right ureter, near the bladder; old adhesions around the uterus. Contraction of the bladder with cystitis. The original fistula only large enough to admit the end of the index finger. Vagina contracted and shortened.

I may say, therefore, in this subject were found all the morbid lesions resulting from kolpokleisis which I pointed out in my paper about the subject (American Journal of Med. Sciences, July, 1870), and which will result in a majority of cases.

The next case Prof. S. tried was a woman from Russia, who had been operated upon successfully by another surgeon nine months before for kolpokleisis. The woman's husband becoming dissatisfied with the shutting up of the vagina, and the little improvement as regarded the retentive power of the bladder, consulted Prof. S. Upon examination he found the fistula small, and therefore proceeded to re-establish the vagina. After effecting the latter, he proceeded to close the fistula itself, situated at the root of the urethra. The operation was performed through my small speculum, which gave Prof. S. great satisfaction. The operation succeeded only to a limited extent, the failure being due probably to the cystitis, which still existed to a slight extent at the time of the operation. Nine or ten days after the operation, the patient had what was supposed to be pyelitis, which probably existed to a slight extent, as a sequence of the kolpokleisis and cystitis.

The fourth case of Prof. S. was a young woman, aged about twenty. She had a small fistula at the root of the urethra, with complete atresia of the vagina above, with no outlet for the menses. Prof. Simon proposed in this case to close the fistula as the first

step of the treatment. But instead of closing the fistula as he intended, he closed the vagina below the fistula, thus making the operation one of kolpokleisis, with no provision for the escape of the menses. The result was only a partial success, and further treatment will be required to complete the occlusion.

Now as to my three cases. The first one presented was a very small woman, with a good-sized fistula involving the cervix uteri. I employed five sutures with a suitable button, and completed the closure at the first operation.

The second case was the one Prof. S. first operated upon with partial success. The fistula was small and involved the cervix uteri, perfectly simple and easy to get at, as shown by the fact that it took only thirty-five minutes to complete the operation. The case was just such a one that I would have guaranteed a cure in eight days, if I had had entire management of the after-treatment. But, as it turned out, the after-treatment was not properly carried out and cystitis resulted, which caused the fistula to reopen two days after the suture apparatus was removed. On the sixth day the closure was found complete, as shown by the fact that not a drop of urine escaped per vaginam during two hours. During this time there was no catheter in the urethra, and the quantity of urine drawn off showed that the retention was complete.

My third case was a woman from Holland, aged about thirty-eight. Prof. S. placed her in his position (the Steiss Kinclage), and with his instruments attempted to display the edge of the fistula, which he utterly failed to do. He stated to his class that he had met with a similar case at Rostock, in which he performed oblique obliteration of the vagina, kolpokleisis, and such an operation he would do in this case, thus cut off the cervix uteri from a vaginal outlet, and place it in communication with the cavity of the bladder. In this way would be made a *cul-de-sac* in the vagina, into which the urine could enter through the fistula, and cause serious trouble, viz.: vaginitis, endometritis, and calculus, with all their attendant symptoms.

After Prof. Simon had finished his remarks upon the case, he requested me to examine the case in my position, with my instruments, and say what I would do under the circumstances. I found the vagina very capacious, and the fistulous opening funnel-shaped, with the apex—the edge of the fistula proper—turned into the bladder and partially united to the right side of the pelvis.

In front of the fistula, in the anterior vaginal wall, there was transverse contraction, which offered an additional obstruction to the view of the fistula. But notwithstanding all those complications in the case, I was able to get a sufficient view of the edge of the fistula, and enable me to say promptly I could unite them, and thus preserve the functions of all the organs involved.

Thereupon, Prof. Simon requested me to perform the operation, as he wished to see it. After dividing the constricted part referred to, and dilating the vagina with tents for ten days, I proceeded to perform the operation indicated for closure of the fistula. The operation proved tedious and protracted, though it was entirely satisfactory. Prof. S. expressed himself satisfied, and said he did not see how it could fail to succeed.

Six or eight hours after the operation, I found an unusually small quantity of urine passing per catheter, which at once aroused my suspicions as to the right ureter being closed between two of my sutures. A few hours later, the patient had great pain in the

right kidney, and then felt a gush of urine into the vagina, with complete relief. When I saw her again, about eighteen hours after the separation, and learned the true story of the case, I told Prof. S. we would have a partial failure of the operation, corresponding to the point at which the right ureter lay in the posterior edge of the fistula. The same accident having occurred some years ago in a case in the Hôtel-Dieu of Paris, upon which I operated, and in other cases, I felt confident of the final result—a partial failure. The removal of the suture apparatus on the eighth day in this case fully confirmed my explanation. A small fistula remained about the middle of the line of cicatrization, which was nearly two inches in length. This remaining fistula is, properly speaking, a vesico-urethro vaginal fistula. Now that the precise situation of the ureter is known, there can be no difficulty in the next operation, when a complete cure may be expected; I shall probably return to Heidelberg and perform it.

At the second operation of Prof. Simon and myself, which we performed the same day, Dr. Koeberlé, of Strassburg, the celebrated ovariologist, was present. He came to Heidelberg and spent two days to see us operate. Prof. Simon frankly admits the superiority of my operation in all cases when the fistula is situated high up. He is delighted with my speculum, and, indeed, has ordered all my instruments to be copied, even my operating chair.

I expect to go to Vienna next week, and if the opportunity offers, will probably operate there.

Yours, etc.,

N. BOZEMAN.

THE PRESBYTERIAN HOSPITAL AFFAIR.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR—Like our friend Dr. Roosa, I also find that something yet remains to be said about the affairs of the Presbyterian Hospital, and the relation they bear to the welfare and honor of the profession. Like him, I would be disposed to smile at the charge of advertising which has been made against the sixty who are supposed to represent the opinions of "the majority of the thoughtful members of the profession." were it not of too trivial importance to be worthy of a place, even as a side issue with questions which concern all who hope to hold honorable positions among us.

It will hardly be profitable to enter into a discussion as to whether those who hold contrary views to the doctor and his fifty-nine or more coadjutors have attained to that degree of acumen which would entitle them to be considered thoughtful, but there is, nevertheless, a large number of physicians who do not entirely agree either with yourself or Dr. Roosa, regarding the nature of the question at issue. Some of them declined to sign the protest, and I may mention, in this connection, that some of the "thoughtful" ones who did are reported to have taken further thought, and modified their views (which shows the advantage of being of a "thoughtful" nature).

The question at issue, as I and others understand it, is: Have the managers of the Presbyterian Hospital a right to enforce a rule established with the Hospital, originated by the only medical member of the Board of Managers, and subscribed to by the gentlemen who lost their places?

Now let us leave all this talk about the dignity of the profession, the duty that we owe to each other, etc., until we are quite sure of what we are talking

about; then we may pat ourselves on the back to our hearts' content, providing you have the room in your columns to admit of an indulgence in so innocent an amusement.

When the Rules and Regulations of the Presbyterian Hospital were being drawn up, the following was put at the head of them—

"1. APPOINTMENTS.

"All the physicians and surgeons connected with the Hospital shall be appointed annually by the Board of Managers."

I have it from excellent authority, that this was, as I have said, introduced by the only medical man who held a position on the Board of Managers; and as he was, or had been at one time or another connected in a responsible capacity with nearly every important hospital in the city, it is to be presumed that he had some good reason for giving this rule so prominent a position in the Regulations. Furthermore, since a large proportion of the medical and surgical staff at the outset had been private students of either himself or his personal friends, or were intimately associated with him in practice or teaching, this clause could not have been particularly obnoxious to what they then considered the interests of themselves or the honor of the profession. In accepting positions under it, they became, with the managers, partners to a contract in which there was not the slightest intimation, expressed or implied, that "cause" should be shown in the event of their non-re-election at any subsequent annual meeting. If they did not like the terms of the agreement, they were at liberty to decline the appointments. The recent attempts on the part of the friends of these gentlemen to coerce the Board of Managers into "showing cause," as well as the efforts that have been made to intimidate those who continued to hold positions on the Medical Board, or might desire to accept appointments on it, smack too strongly of the spirit of trade-unionism to reflect much credit upon the "thoughtful" members of the profession who have been so demonstrative.

If, instead of disputing in so public and impressive a manner the right of the Board of Managers to administer the affairs of the Hospital according to the published rules, these sixty or more champions of professional honor had remonstrated against the *existence*, among the regulations of the Presbyterian, or any other hospital, of such a standing rule as the one above cited; had urged the importance and justice of having at least as large a medical element in the Board of Managers of this hospital as there is of the clerical profession; had recommended that the duration of service of the attending physicians and surgeons should at least correspond to that of the managers, with eligibility to re-election, and the services of consulting physicians and surgeons should be for life, or the pleasure of the Board, then no one but those who wish to have our hospitals managed in the interests of a clique, could fail to respect the sentiments or actions of the signers of such a document, be they six, sixty, or six hundred, and least of all a Board of Managers of the character like the one under consideration.

That this protest, as an advance of medical unity and *esprit de corps* in the aroused sense of fair play, is anything more than apparent, I beg leave to doubt. There is no question that *if* it should be kept up, it might bring about that millennium in hospital relationships which the Doctor hopes for, but until some of the persons who were so active in soliciting signatures to the protest, and writing inflammatory letters to the daily press, choose to exert themselves in the interest

of other members of the medical profession than their personal friends and relatives, there will be unthinking persons who will ask better evidence than Dr. Roosa's hopes to convince them, that the profession have anything to gain by lending their aid to tighten the hold by which the clique who have attempted to govern our hospital appointments retain the places they have held for so many years.

Some of the writers in the *Tribune* have chosen to refer to the managers as holding their places in trust for those who have subscribed to the endowment and support of the Hospital, and have questioned their right to act in a manner so arbitrary and contrary to the wishes of the patrons of the institutions. I have no means of knowing who were in the majority or who were in the minority of the members voting at the annual meeting, but any one who will take the trouble to consult the Annual Reports of the institution may observe that something over \$860,000 have been paid into the treasury by the managers themselves, their immediate relatives, and those whose opinions they are known to represent, against about \$150,000 from other sources. As to who have the best right to manage the affairs of a hospital thus supported, there can be but little question.

I fail to appreciate the motive which could have led to the adoption of the rule of annual election, since it is in spirit manifestly unjust to both the Hospital and its medical board. The one cannot afford to dispense with the trained services of its physicians and surgeons; and desirable medical attendants could hardly be secured without a reasonable immunity from sudden changes like the one which has given occasion for this controversy. Yet another question is involved in this matter of hospital appointments which is quite as important as this. It is becoming quite the thing to talk about the duties which the profession owe to the public, and just now it seems that one of them seems to be the publication of medical papers and society transactions in the secular press. Have not the public a right, likewise, to skilled medical attendants, and if the "public," as we are frequently told, support hospitals and dispensaries for the advancement of the science of medicine, as well as for the relief of suffering, have they not a right to as large a return, proportionately, in the former way as in the latter? May not quite as much be done to increase the *esprit de corps* and intelligence of the graduated physician by affording him a reasonable chance for a hospital service, as by "raising the standard" of our medical schools? No one knows better than yourself the number of medical men in our city who are as worthy by training and intelligence to hold hospital appointments as the favored few who, by fortune, favoritism, and family, quite as much as by merit, have gained the positions they expect to hold for life, or until they choose to resign them.

The establishment of a limit to the term of service, which, while it would insure to the hospital the services of a trained and skilful professional corps, would also afford the advantages of hospital practice to the largest number of worthy physicians; would stimulate those holding such appointments to make the most of their advantages during their terms of service, and, by making the acquisition of hospital appointments easier to the younger members of the profession, would encourage them to gain such positions by merit rather than by the "fawning" to which Dr. Roosa so eloquently alludes.

Like Judge Neilson, of Brooklyn, I have a number of opinions, which I have been waiting some time for an opportunity to ventilate, but I feel that I have said

about as much this time as you are likely to have space for.

JUSTITIA.

HOMŒOPATHY IN THE UNIVERSITY OF MICHIGAN.

UNIVERSITY OF MICHIGAN,
ANN ARBOR, July 13, 1875.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—You are in error in your brief editorial in *RECORD* of Saturday last, and have done the Regents of this University an injustice by asserting that an attempt is being made, on their part, "to appoint one or two homœopathic professors, ostensibly to take charge of the new department, but in reality to become by law members of the faculty." If you will refer to the bill, establishing the College of Homœopathy, published a few weeks since in full in your own columns, you will see that this assertion is not true. The homœopathic professors are not, and by the very terms of the act cannot be, members of the faculty of the now existing department of medicine; nor, on the other hand, are the professors in this, the old school, members of the faculty of the Homœopathic College, for both schools have separate statutory enactments, creating them distinct and independent departments of the University.

Your article is furthermore *doubly* unjust to the Regents, from the fact that they have twice refused peremptorily to obey the Legislature, when it attempted to force such "disagreeable and unprofitable associations," by enacting the appointment of homœopathic professors in the old department of medicine. This offensive feature having been removed in the last act, the Regents have accepted the legislative grant of money, and have established the new college.

Very respectfully,

E. S. DUNSTER, M.D.

[We very cheerfully give place to Prof. Dunster's letter. At the time of writing the article referred to we believed that the statements furnished us were founded on fact.]

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from July 11th to July 17th, 1875.

HEAD, J. F., Surgeon and Medical Director.—Leave of absence extended 25 days. S. O. 21, Mil. Division of the South, July 8, 1875.

FRYER, B. E., Surgeon.—Relieved from duty at Fort Wadsworth, N. Y. II. S. O. 135, Mil. Division of the Atlantic, July 10, 1875.

HALL, J. D., Assistant Surgeon.—Relieved from duty in Dept. of Dakota, to report to the President of the Army Medical Board, New York City, for examination for promotion, and, upon its conclusion, by letter to the Surgeon-General. S. O. 135, A. G. O., July 8, 1875.

COWDREY, S. G., Assistant Surgeon.—Granted leave of absence for four months. S. O. 139, A. G. O., July 12, 1875.

AINSWORTH, F. C., Assistant Surgeon.—Relieved from duty at the U. S. Mil. Academy, and to report by letter to the Surgeon-General. S. O. 141, A. G. O., July 13, 1875.

LORD, GEO. E., Assistant Surgeon.—Assigned to duty at Fort Snelling, Minn. S. O. 128, Dept. of Dakota, July 8, 1875.

July 15th.

CASSIN, CHARLES L., Passed Assistant Surgeon.—Ordered to the *Frolic*.

LOVERING, P. A., Assistant Surgeon.—Ordered to the Receiving Ship *Ohio*.

SIMONS, M. A.—Detached from the Receiving Ship *Ohio* and ordered to the Boston Navy Yard.

July 17th.

GREENE, V. T., Acting Passed Assistant Surgeon.—Detached from the *Lancaster* and awaiting orders.

Medical Items and News.

RANK OF MEDICAL CORPS OF THE ARMY.—The American Medical Association, at its recent meeting held in Louisville, appointed the following gentlemen as a Committee on the Rank of the Medical Corps of the Army: Drs. H. A. Johnson, Chicago; John P. Gray, Utica; E. L. Howard, Baltimore; George F. Shady, New York, and Horatio C. Wood, Jr., Philadelphia.

LONG ISLAND COLLEGE HOSPITAL.—At the sixteenth annual commencement of this college, the degree of Doctor in Medicine was conferred upon forty-four graduates.

Prizes, consisting of sets of instruments, were awarded to Evan B. Jones, for the best report of clinical lectures, and to Berridge C. K. Lucas, for the best report of didactic lectures; also a Rockwell's forceps to E. C. Dudley, for the second best report. An oration was then delivered by John G. Saxe, LL.D., on the relation of physician and patient, and some of the annoyances of the medical profession.

The valedictory address, on the progress of the science of medicine, was delivered by E. C. Dudley, M.D.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.—The twenty-second annual commencement of this school took place on June 24, at Middlebury. President Buckham conferred degrees on thirty graduates, after which Dr. L. C. Butler welcomed the class to the profession. After the distribution of prizes an address was delivered by Professor A. F. A. King, and the valedictory by Mr. Edward R. Campbell.

The college authorities announce the following change in the Faculty: Dr. J. L. Little, who for many years has held the position as Lecturer on Operative Surgery and Surgical Dressings in the College of Physicians and Surgeons of New York, and who is one of the Surgeons to St. Luke's and St. Vincent's Hospitals, has been elected to fill the chair of the Principles and Practice of Surgery in this institution.

Dr. D. B. St. John Roosa, who has for many years occupied the chair of Diseases of the Eye and Ear in the University of New York, will deliver a course of lectures on "Ophthalmology" and "Otology" during the college term. Dr. R. W. Taylor, late Professor of Dermatology in the Woman's Medical College of New York, will deliver a course of lectures on Diseases of the Skin. Dr. S. M. Roberts, Professor of Diseases of Children in the Woman's Medical College of New York, will also deliver a course of lectures on that subject.

THE MEDICAL ASSOCIATION OF THE STATE OF MISSOURI, at its ninth annual meeting, held at Jefferson City on the 20th and 21st of April last, elected John T. Hodgen, of St. Louis, President for the ensuing year; F. M. Johnson, J. M. Allen, J. L. B. Alleyne, J. T. Wilson, and G. B. Winston, Vice-Presidents; E. M. Schaufliker, of Kansas City, and H. N. Spencer, of St. Louis, Recording Secretaries; John H. Britts, of Clinton, Corresponding Secretary; and A. N. Kineannon, Treasurer. The next meeting of the Society is to be at St. Louis, on the third Tuesday in April next.

BOYLSTON MEDICAL PRIZE QUESTIONS.—The Boylston Medical Committee, appointed by the President and Fellows of Harvard University, consists of the following physicians: Drs. J. B. S. Jackson, H. R. Storer, Merrill Wyman, Henry J. Bigelow, Richard M. Hodges, Calvin Ellis, and Samuel Cabot. At the annual meeting, held June 7, 1875, it was voted that no dissertation worthy of a prize had been offered on either of the subjects proposed for 1875.

The following are the questions proposed for 1876: 1. Civil Hospital Construction (not of Lunatic Asylums): Location, Materials, Arrangements, Warming, Ventilation, Drainage, lighting; with Designs.

The author of a dissertation on this subject considered worthy of a prize, will be entitled to a premium of three hundred dollars.

2. Do Women require mental and bodily rest during menstruation; and to what extent? The author of a dissertation on this subject, considered worthy of a prize, will be entitled to a premium of two hundred dollars. Dissertations on the above subjects must be transmitted, postpaid, to J. B. S. Jackson, M.D., Boston, on or before the first Wednesday in April, 1876.

The following are the questions proposed for 1877:

1. Are Epidemics, and so-called contagious diseases, necessarily dependent upon material agencies, acting through the stomach, or otherwise? 2. Athletic Sports, Training, Violent Exercises, etc., as now practised by young men; their temporary or permanent influence on the health. The author of a dissertation, considered worthy of a prize, on either of the subjects proposed for 1877, will be entitled to a premium of two hundred and fifty dollars.

Dissertations on these subjects must be transmitted as above, on or before the first Wednesday in April, 1877. Each dissertation must be accompanied by a sealed packet on which shall be written some device or sentence, and within which shall be enclosed the author's name and residence. The same device or sentence is to be written on the dissertation to which the packet is attached.

The writer of each dissertation is expected to transmit his communication to the President of the Committee, J. B. S. Jackson, M.D., in a distinct and plain handwriting, and with the pages bound in book-form, within the time specified. Any clue by which the authorship of a dissertation is made known to the Committee will debar such dissertation from competition. Preference will be given to dissertations which exhibit original work. All unsuccessful dissertations are deposited with the Secretary, from whom they may be obtained, with the sealed packet unopened, if called for within one year after they have been received.

By an order adopted in 1826, the Secretary was directed to publish annually the following votes:— 1st. That the Board do not consider themselves as approving the doctrines contained in any of the dissertations to which premiums may be adjudged. 2d. That in case of publication of a successful dissertation, the author be considered as bound to print the above vote in connection therewith.

Original Communications.

ANALYSIS OF THREE HUNDRED AND TWENTY-TWO (322) CASES OF FRACTURE OF THE FEMUR AT BELLEVUE HOSPITAL, FROM 1865 TO 1873 INCLUSIVE.

By FREDERICK E. HYDE, M.D.,

NEW YORK.

I was led to compile the following tables from having at my command the necessary data, obtained from the records of Bellevue Hospital last year for another purpose, but which I have here still further elaborated. As far as I have been able to ascertain, this is the largest number of cases of fracture of the thigh that has been analyzed and arranged in tabular form. Malgaigne's cases come next as to numbers, he having recorded three hundred and eight cases, extending over eleven years.

I have endeavored to present in these tables a careful transcription of the records for the time specified, as a contribution of facts upon the various points which they bring forward.

Table A has reference to the point of fracture; Table B to the character of the fracture; and Table C to the age of the patient.

In Table A I have considered six points of fracture; two of the neck, intra- and extra-capsular; three of the shaft, the upper, middle, and lower thirds; and fractures of the condyles. Fractures occurring at the junction of the middle third with the upper and lower thirds I have included with those of the middle third: this is justifiable upon the ground that such fractures are produced in the same manner, they are not far enough from the middle point of the bone to require different treatment, and they have the same general results. Fractures of the trochanters I have included with fractures of the upper third.

Under each of the above headings I have given the number of cases occurring, the sex, character of the fracture, result as to cure, the number of days the splint remained on, the average amount of shortening, both excluding and including recoveries without shortening, together with other points of lesser interest.

The large proportion of fractures of the neck not classified would seem to indicate the difficulty of diagnosing such fractures, as there are 30 fractures not classified, and but 31 classified; 14 intra-capsular, and 17 extra-capsular. Of intra-capsular fractures the larger proportion occurred in females, 10 to 4; whereas, of the extra-capsular, the larger proportion were in males, 11 to 6. Of 61 fractures of the neck the character is indicated in 50 cases, all of which are simple fractures, three only having complications. When we remember the facility with which this portion of the femur is broken in advanced years (as see Table C), and consider the manner in which such fractures are caused, as well as the great depth of covering, we will not look for a compound fracture at this point, unless it be a gunshot injury.

There are four cases of non union of intra-capsular fractures recorded, and none of extra-capsular fractures, bearing out the observations of others upon this point, that extra-capsular fractures, as a rule, unite, whereas very many intra-capsular fractures remain permanently ununited.

No cases are on record, of fracture at this point, in which union took place without shortening. The number of cases recorded of recovery with shortening is so small that they are of no value in estimating results.

Of fractures of the shaft there are 254 cases, very much the larger number being of the middle third, namely, 168; while fractures of the upper and lower thirds are about equal in number, 34 of the former and 32 of the latter. Of the total number of fractures of the shaft, 201 occurred in males and 46 in females, in 7 cases the sex is not recorded. 187 were simple fractures and 35 compound. It is of importance to note that where the point of fracture is indicated, no cases of non-union are recorded, and even in the total number of fractures of the shaft, 254, there are but 2 cases, which is certainly a very small proportion. This fact would lead us naturally to inquire whether any special method of treatment had produced this result, but the cases occurring during the nine years included in the tables were treated by a variety of methods, running through double-inclined-plane, Buck's extension and plaster, so that the kind of treatment has had no observable effect, and I think that the small number of cases recorded would seem to indicate that there is very little tendency to non-union in the shaft of this bone, much less, indeed, than has generally been supposed.

The percentage of deaths is about the same in both fractures of the neck and shaft, being about 12 per cent. in the latter and 13 per cent. in the former. It must be borne in mind in this comparison, however, that in fractures of the neck no compound fractures are included, so that we have a greater fatality in these fractures, due, not so much to the lesion itself, as probably to the shock to the system at the advanced age at which it most generally occurs.

I have given the number of days the splint remained on, in order that an approximative idea might be formed as to the length of time required for a fractured femur to unite. In fractures of the shaft the average time was $41\frac{1}{2}$ days, or about 6 weeks, the number of cases averaged being 37, the shortest time 25 days—a child 3 years of age, middle third—the longest time 102 days. In fractures of the neck, out of the 61 cases, but 3 are recorded in which the time the splint was on could be ascertained. These averaged about 6 weeks, but the number of cases is too small to be of value.

There are 18 cases of fracture of the shaft recorded as not-shortened: 3 of the upper third, 14 of the middle third, and one of the lower third. Two of these "not-shortened" limbs are recorded as having been lengthened under treatment, so that the sound limb is shorter than the fractured one. They are the following:

CASE 1.—Simple fracture, middle third, male, 6 years of age, $\frac{1}{4}$ inch longer than normal. Plaster-of-Paris splint applied under anæsthetic: causing pain, it was cut open, and Buck's extension applied.

CASE 2.—Simple fracture, middle third, male, 28 years of age, $\frac{1}{2}$ inch longer than normal. Plaster-of-Paris splint, including pelvis, was applied under ether; "strong extension;" on 6th day the plaster, causing pain, was cut at the waist; on 8th day was cut up to the knee; 40th day the plaster splint was removed.

I will take the liberty of introducing here an additional case of lengthening after fracture, which occurred since the tables were compiled. It was a case at Bellevue Hospital, under the care of Dr. Frank H. Hamilton, of simple fracture, middle third, male about 35 years of age, $\frac{1}{4}$ inch longer than normal

TABLE A, HAVING REFERENCE TO THE POINT OF FRACTURE.

Point of Fracture.	No. of Cases.		Character of Fracture.							Result as to Cure.				No. of Days Splint Remained on.				Shortening.

In addition to the above there is 1 case of simple comminuted and complicated fracture of the lower third, 2 cases of compound comminuted and complicated of the middle third, and 4 comminuted, other characters of which not stated, 1 in the upper third, 2 in the lower third, and 1 of the condyles.

1 Sex not recorded in four cases of middle third, one case of lower third, and two cases of point fracture not indicated.
 2 One of these cases a gunshot wound.
 3 This case had a simple fracture of the other thigh also, with the additional complication of fracture of skull.
 4 One of these cases was a double fracture.

Treatment exclusively by Buck's extension. I was present at a critical measurement of the limbs, and can vouch for its accuracy.

Of fracture of the shaft 81 cases resulted in shortening, 12 in the upper third, with an average shortening, excluding limbs not-shortened, of about $\frac{1}{2}$ of an inch; including limbs not-shortened, about $\frac{1}{4}$ of an inch. In the middle third there are 54 shortened limbs, with an average shortening, excluding limbs not-shortened, of $\frac{1}{2}$ of an inch; including limbs not-shortened, about $\frac{1}{2}$ of an inch. In the lower third 9 cases, excluding limbs not-shortened, the average shortening is $\frac{1}{2}$ of an inch; including limbs not-shortened, the average shortening is $\frac{1}{2}$ of an inch; least shortening is $\frac{1}{4}$ of an inch, the greatest shortening 3 inches; the average, excluding cases not-shortened, is about $\frac{1}{2}$ of an inch; including cases not-shortened, about $\frac{1}{2}$ of an inch. In the summary of fractures at all points of the femur the

actual difference in the averages of shortening, excluding and including cases not-shortened, is shown to be not quite $\frac{1}{4}$ of an inch, or .83 of an eighth. Fractures of the condyles are but few, there being but 7 cases in 322, recorded as such.

It may be noticed that in my column of not-shortened there is one case less than appeared in the table published in the *New York Medical Journal* for last October. This was a case of double fracture in which union had taken place with both limbs of the same length. This result, however, does not imply that there was no shortening, so I have excluded the case from the column of not-shortened in these tables.

Table B, having reference to the character of the fracture, contains percentages of non-union and deaths, averages of the time the splints were kept on, and of

* One case in hospital 358 days makes this average high.

the time that patients remained in hospital—the latter always referring to patients that were discharged cured; and averages of shortening. This table also brings out very strongly the fact that in several points there is very little difference in the results of treatment of simple and compound fractures.

There are 243 simple and 37 compound fractures, including their various subdivisions. The percentages of non-union are about the same in both, being 2.46 per cent. in simple fractures, and 2.7 per cent. in compound. In the percentages of deaths there is, however, a striking difference: in simple fractures there are 7 per cent. of deaths, while in compound fractures the deaths are 43 per cent. With regard to the time the splints remained on, as indicating the time required for the bone to unite, the statistics under compound fractures are too meagre to be of any value; the treatment also being so much more complicated no comparison is admissible. The average of 36 cases of simple fracture is 41³/₅ days, or about 6 weeks, as the approximative time required for a simple fracture to unite; add to this about 4 weeks' convalescence, and we have 10 weeks, the average time that the patient remains in the hospital.

As to the shortening, there is no appreciable difference in the results. I find 16 cases of simple fracture without shortening, and 1 compound. Of shortened limbs there are 78 simple, 6 compound, and 1 comminuted. The shortening in both simple and compound fractures, excluding not-shortened, is about ⁵/₈ of an inch; including not-shortened, about ¹/₂ an inch. The comminuted fracture had but ¹/₂ an inch shortening.

In Table C I have made the age of the patient the basis of my observations. Separating the ages into decades, in each decade I have given the number of cases under each age, the sex, point of fracture, result as to cure, the time the splint was on, the time the pa-

tient was in hospital, and averages of shortening. Fractures occur most often in the 1st, 3d, and 4th decades, reaching the highest number in the 4th decade.

Of the fifty-one cases in the 1st decade, 44 are of the middle third, 4 of the upper third, and 3 of the lower third. It is to be noticed that they are all fractures of the shaft of the bone. In the 2d decade there are 2 fractures of the neck, in addition to the larger number in the middle third. In the 3d decade 5 are of the neck; in the 4th decade, of 57 fractures 9 are of the neck, while fractures of the lower third reach their maximum, 10 cases. In the 5th decade there are 8 fractures of the neck to 19 of the middle third and 5 of the lower third, in 43 cases. In the 6th decade, of 40 cases, 14 are of the neck, 7 of the upper third, 11 of the middle third, and 7 of the lower; advancing years causing a gradual change in the location of the fracture. In the 7th decade, of 28 cases, 15 are of the neck, and but 4 of the middle third. In the 8th decade, of 9 cases, 7 are of the neck, and 2 of the upper third; and in the 9th decade, of 3 cases, 1 is of the neck, and 2 of the middle third.

An analysis of fractures of the neck, giving their percentages of the total number of fractures occurring in each decade, seems to me to show more clearly than by any other method the relative frequency of these fractures at different periods of life. The records bring them to our notice as follows:

	INT.-CAP.	P. CT.	EX.-CAP.	P. CT.
Between 10 and 20 years....	None	1 or	2.50
" 20 " 30 ".....	1 "	2.0
" 30 " 40 ".....	1 or	1.75	and 5 "	8.77
" 40 " 50 ".....	2 "	4.65	" 3 "	6.97
" 50 " 60 ".....	3 "	7.49	" 1 "	2.50
" 60 " 70 ".....	5 "	17.85	" 4 "	14.28
" 70 " 80 ".....	3 "	33.33	" 1 "	11.11

From the above tabular statement we learn that the percentage of extra-capsular fractures is far in excess

79.....	2	2	2											2									
Totals ..	9	5	4	7	2			5		2	2	1	4	2			2	45		2	5	5	

NOTE.—Included in fractures of the neck are: 3 intra-capsular—at 73, 74, and 79 years respectively; 1 extra-capsular at 79 years. There are 2 simple complicated fractures at 79 years.

85.....	1	1	1					1							1							
87.....	1	1			1									1								
90.....	1	1			1									1								
Totals ..	3	2	1	1	2			1						2	1							

NOTE.—In addition to the simple fracture there are, 1 simple complicated at 87 years, and 1 compound comminuted at 90 years. There are four cases recorded in which the age is not stated—1 female and 3 male; 2 fractures at the middle third, and 2 point not stated; all were simple. Union was recorded in 1 case; death in 1, and in 2 cases result not stated. Shortening recorded in 1 case of 2 eighths.

of that of the intra-capsular, up to and including the 4th decade; they are about equal in the 5th decade, and beyond this period the intra-capsular are of more frequent occurrence.

Regarding the character of the fracture, the largest proportionate number of simple fractures is in the 1st decade, 43 cases in 51; the compound fractures being in about the same proportion in the 1st, 3d, and 4th decades.

No case of non-union is recorded until the 29th year, when we find 1 case; then as follows: 1 at 37 years; 1 at 39 years; 1 at 50 years; 1 at 55 years; 1 at 60 years; 1 at 65 years; and 1 at 74 years.

The time the splint was on, or time required for union of the fracture, is in the 1st decade about 4½ weeks; in the 2d decade about 6 weeks; in the 3d de-

cade 5½ weeks; in the 4th decade 6½ weeks; in the 5th decade 6 weeks; in the 6th decade 9½ weeks, one case in this decade having the splints applied for 102 days makes this average high; in the 7th decade 7 weeks; in the 8th and 9th decades there is no record of this point. We find in each decade the usual 3 to 4 weeks of convalescence additional to complete the period in hospital.

With regard to shortening and no shortening, the best results were obtained under ten years of age, where out of 30 cases measured, 7 limbs were recorded as not-shortened; the average shortening, excluding cases not-shortened, being ¾ of an inch, and including cases not-shortened ¾ of an inch. The worst results are found in the 8th decade, where out of 7 cases measured 1 is recorded as not-shortened, the average shortening, ex-

cluding this case, being one inch, and including it, $\frac{3}{4}$ of an inch. Between these extremes we notice that the cases in which there is no shortening gradually decrease in numbers as years advance, being 3 in the 2d and 3d decades respectively; 2 in the 4th decade; and 1 each in the 5th, 6th, and 7th decades. Excluding cases not-shortened, the shortening in the 2d and 3d decades is about $\frac{1}{2}$ of an inch; in the 4th and 6th decades $\frac{3}{4}$ of an inch; in the 5th decade $\frac{1}{2}$ of an inch; in the 7th decade 1 inch; in the 8th decade the statistics are so meagre that they show no positive results. Including cases not-shortened, in the 2d and 3d decades the shortening is $\frac{1}{2}$ an inch; in the 4th and 6th decades $\frac{3}{4}$ of an inch; in the 5th decade $\frac{1}{2}$ of an inch; and in the 7th decade $\frac{3}{4}$ of an inch. The difference in the averages, excluding and including cases not-shortened, being about $\frac{1}{8}$ of an inch, or actually .83 of an eighth, as we saw in considering Table A.

I have endeavored to bring out in the above remarks on the tables, the main points which they contain. They are, however, susceptible of still further inter-comparison, which the limits of this paper would not properly admit of. In a note below each table there are additional cases, left out of the tabular forms to avoid occupying more space.

A "SPEEDY METHOD" IN ASPHYXIA.

By HARVEY L. BYRD, M.D., ETC.,

BALTIMORE, MD.

It is hardly necessary in an article like this to urge professional attention to the vast importance, in a medico-legal point of view, of establishing, even for a moment or two, the vitally necessary function of respiration in the newly-born infant. And whether a child be considered a "living soul" or not ere breathing occurs, all will agree that humanity calls loudly for prompt and efficient action at the hand of the officiating accoucheur for the development of the respiratory process in all cases where children emerge into the world in an asphyxiated condition.

Asphyxia is liable to be produced by a variety of causes; and every abnormal state or unusual circumstance occurring during labor likely to result in this critical and dangerous condition to the infant, should be carefully weighed by the attending obstetrician, so as to be prepared to promptly meet the emergency, should it arise. On the announcement to the profession of Dr. Marshall Hall's "ready method" in asphyxia, some years ago, and its practical application in a few cases, the writer thought there was very little, if any, further addition necessary to the list of remedial agents in the asphyxia of newly-born infants. Later experience, however, with this and subsequently published "methods," proved that, occasionally at least, all the then known appliances were futile, and further knowledge required to secure success in the management of this very dangerous condition of the infant. The following "method," it is believed, will be found a highly valuable, if not the most important addition to our list of appliances in the asphyxia of children, and also for the relief of that condition in the adult, when properly applied. The procedure is easy of accomplishment, and requires no preliminary arrangement or preparation for its application, but may be put into execution the moment the condition of the child may demand it. It is as follows: Bring the *ulnar* sides of the hands near together, with the palmar surfaces looking vertically, and place them beneath the

back of the infant, so that the extended thumbs may aid, as far as possible, in sustaining the vertex and inferior extremities; then, keeping the *ulnar borders* near together so as to form a fulcrum, the radial bor-

No. 1

No. 2.

ders or sides are simultaneously depressed to as great extent as practicable—say forty-five degrees—below the horizontal line, and then gradually pronated or elevated to as many degrees above that line, thus facilitating the escape of air drawn into the lungs during the downward movement of the head and chest. Or the hands are placed as at first, and passed beneath the body of the child—on its back—and the superior and inferior extremities furthest from the operator seized, one by each hand, near the trunk—the *ulnar borders* of the hands and wrists forming the fulcrum—the head of the child being kept at a proper axis with the movements of the chest by the hands of an assistant; and the depression and elevation of the head and lower extremities proceeded with as already described. These alternate depressions and elevations of the two extremities, performed in a regular and gentle manner, and repeated at proper intervals, seldom fail in establishing respiration where it is possible of accomplish-

No. 3

ment. The occasional dashing of cold water on the epigastrium during the descent of the head and chest will hasten respiration where the first few movements fail in its establishment. It is important that the head be kept, as far as practicable, from too much lateral movement, and not permitted to depart considerably from its antero-posterior axis with the vertebral column during the continuance of the process. To this end, in a critical case, the hands of an assistant may be brought into requisition. The importance of these remarks will be apparent to intelligent readers on a moment's reflection. No impediment should be permitted in the way of free entrance of air into the lungs during the downward movement of the head,

and it is scarcely less important that no obstruction should oppose the escape of air during the upward movement of the head and chest. The philosophy of the above-described movements will be easily comprehended by a glance at the accompanying wood-cuts. A nurse or other intelligent attendant can be made to understand the movements, so as to continue them should the condition of the mother demand the attention of the accoucheur. These movements will apply to the treatment of asphyxiated persons of any age, as has been practically demonstrated in several cases since the publication of my first article on the subject. Asphyxia from drowning has been promptly overcome in three instances since the question was asked in a former communication—on theoretical grounds—whether it would not act more promptly than any other method. It has been found that the "movements" are easily practised when the body is taken from the water and placed on its back across a barrel, trunk of a fallen tree, or other substance. Two persons can thus depress and elevate the extremities as often as necessary to expand and exhaust the air in the lungs, as in normal respiration. The epiglottis acts in these movements in a manner similar to the valve of an ordinary bellows when being used. Since the first article appeared—in 1870—on the value of the "speedy method," quite a number of cases of asphyxia have been treated by it, and its value thoroughly tested in my own practice, and in consultation with professional friends, and always with the most gratifying results. Further experience has proven that where a sufficiently large tub or basin of warm water can be had, the movements already described may be carried more easily into operation than otherwise. Care should always be had, of course, to avoid depressing the head to such an extent as to permit the water to enter the mouth or nostrils of the child during the operation. In practising the "method" in the water the head need not at any time be elevated above the surface—the body of the child alone being elevated or depressed—for the inflation and exhaustion of the air in and from the lungs. A number of cases could be recorded in favor of the method since the previous reports were made, but they are deemed unnecessary at this time. The object of this communication is to give greater publicity to a most important remedial procedure, and we may here repeat what has already been proven to be true by many practitioners, "that those who may have occasion to employ this method will agree with us that in the asphyxia of children it is the remedy *par excellence*."

266 NORTH FREMONT ST., July 2, 1875.

THE RICHMOND COUNTY MEDICAL SOCIETY has elected the following-named officers for the year:—*President*, Dr. C. Henry King; *Vice-President*, Dr. Frank E. Martindale; *Treasurer*, Dr. Isaac L. Mills-paugh; *Secretary*, Dr. Edward F. Arnoux; *State Delegate*, Dr. J. J. Van Rensselaer; *Censors*, Drs. A. L. Carroll, Theodore Walser, and R. H. Golder.

THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NASHVILLE AND VANDERBILT UNIVERSITY have commenced building a hospital on the college grounds, which is to have a frontage of one hundred and sixty-two feet, and a height of two or three stories. It is to possess all the modern conveniences and improvements, and is to have accommodation for two hundred and fifty to three hundred patients.

THE HOMEOPATHISTS OF OHIO have resolved to oppose the creation of a State Board of Health.

Progress of Medical Science.

OVARIOTOMY COMPLICATED WITH PREGNANCY—CESAREAN OPERATION—CURE.—Mr. Thomas Hillas, at a meeting of the Medical Society of Victoria, Australia, held in December, 1874, gave the account of the following case: The patient, aged twenty-four years, single, was admitted to the Ballarat District Hospital June 4th, 1872. The history of her case was peculiar. She believed that she became pregnant in March, 1871. She was admitted to the lying-in ward of the Ballarat Benevolent Asylum in November, 1871, and after staying there until the following June, a consultation was held and she was discharged, her case being deemed ovarian dropsy, and not pregnancy. On her admission to the hospital she was examined by the staff, all agreeing that she was suffering from ovarian dropsy, and that it was a suitable case for operation. On June 13th, the patient being chloroformed, Mr. Hillas commenced the operation by an incision midway between the umbilicus and pubes. Mr. Hillas says: "On arriving at the peritoneum, I made a small opening into it, when out spurted a large jet of venous blood, which the pressure of the finger controlled. I came to the conclusion I had wounded, unwittingly, a gravid uterus, and feeling sure of this, I extended the first incision upwards to the umbilicus, when a large uterus rolled out on to the thighs, and the ovarian sac protruded." The latter was tapped, and about eleven quarts of fluid withdrawn. The pedicle was short and thick, and after being tied firmly with a double whipcord ligature, the clamp was securely applied and the pedicle divided, the ends of the double ligature being tied over the ends of the clamp. The question then arose, what was to be done with the uterus, which was all this time lying on the thighs, with a fetus in it, and a wound through its muscles, probably into the placenta.

Some advised that the wound should be sewn up, and the organ replaced in the abdomen, but seeing that labor must soon come on, and thinking that rupture of the uterus would most likely occur at the seat of injury, Mr. Hillas decided to perform the Cesarean operation, as being the most likely means of giving the patient a chance to recover. The uterus was incised to about five inches, and the placenta and a fetus, alive and well developed, at about the eighth month of gestation, extracted. The wound in the uterus was then closed with silver-wire sutures, the cut ends being carefully tucked down into the incision. The uterus then contracted firmly. The wound of the abdomen was then closed, the clamp being left at the lower margin of the wound, and a good deal dragged upon. The right ovary was the one affected. The patient measured sixty inches around the abdomen before the operation. The sac and its contents weighed thirteen pounds. The patient vomited for about forty-eight hours after the operation, having been an hour under chloroform. This was relieved by morphia and ice, and on the fourth day all unfavorable symptoms abated. There was a discharge of pus from the lower portion of the wound, which ceased in about a fortnight, and then it completely healed. She was discharged, cured, at the end of six weeks. On July 3d, a month after the operation, she menstruated moderately for four days, and again on August 28th.

Mr. Hillas has seen her several times since, and reports her to be in perfect health.—*The Australian Medical Journal*, Melbourne, February, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 31, 1875.

THE SMALL FEE SYSTEM.

From the very nature of the case it is presumed that physicians will never tire of interest in what concerns their pecuniary welfare. Whatever we may say of the honor and dignity of our profession, we cannot afford to lose sight of the fee which makes the position which we assume the more enjoyable. It is a well-accepted saying, that the practice of our profession rarely insures a fortune, the ordinary rule being a decent and respectable livelihood. This being the case, the question presents itself whether or not we are particular enough to collect all we can from our patients. As honorable men we should of course scorn to take advantage of the wealth of our patrons, but is it judicious and proper for us to ignore compensation from such as may not be pecuniarily competent to pay our ordinary fees? It is by many considered so undignified to accept a small fee, that sooner than do it they would give their services for nothing. Aside from the abuse of medical charity which such a course may engender, it is committing a wrong to the patient as well as to the physician.

In the first place, the patient naturally feels under obligation to a physician whom he has employed, and very naturally it is a duty, a privilege, and a pleasure to discharge it to the best of his pecuniary ability. Because he may be a poor man he should not be demed this right. Viewing the fee of the physician in the light of an honorarium, it is impossible to give to it any fixed value. The importance of the service cannot justify the measure of the reward, inasmuch as so many conditions and qualifying circumstances must be taken into account. This implies a latitude of discretion on our part which it is allowable to use, independent of any of the arbitrary provisions of the fee-bill. If, on the one hand, we may feel ourselves warranted in receiving extra compensation from the millionaire, we have an equal right to accept the mite of the poorer man. The same principle which

holds good in one case is equally good in the other. We believe it is a mistaken policy on the part of medical men to decline to accept any fee because it may be disproportionately small to the degree and extent of the services rendered.

It is well known that many of our bills are not easy to collect, and if we add these to such as we decline to accept, because they appear by comparison too small to be of any account, we shall find that in the long run a good deal of hard professional work counts for nothing. We lose enough in the failure to collect what we may deem our legitimate fees to make us reasonably careful about the smaller and apparently insignificant ones. The mere fact of our taking a small compensation does not by any means prove that our services are not worth more, only that the patient is incapable of paying us more. Small and even insignificant fees are so much better than none at all, that it is a matter of surprise that they are not more frequently accepted. And after all, is it not perfectly proper that we should offset these against the larger sums of which we are so often cheated. In the aggregate they may amount to a very respectable sum. It has been asserted by a writer who has examined into the subject that many of the larger incomes of the leading practitioners abroad is due, in the main, to the steady and continual accumulation of the smaller amounts. Even in this country we have striking examples of the wisdom of this policy.

The President of one of the State Societies has advocated the charging of small fees to patients, who would otherwise be sent to our medical charities, for the purpose of creating a fund for the support of the widows and orphans of medical men. This is a very laudable object, but is only one of many to which we may be enabled to direct our energies and be none the poorer for the contribution. How many privations in a pecuniary point of view may be overcome by attention to these minor matters of money getting, and how many innocent luxuries can be indulged in to which as hard workers we are justly entitled.

The main object of a recognized tariff of prices is mutual protection; but by departing from the standard in the particular cases to which we refer, no harm can come. There is no encouragement to any system of underbidding or of cheapening medical services; the only proposition is to collect small fees which would otherwise be entirely lost.

ROYAL COMMISSION ON VIVISECTION.—The following-named gentlemen have been appointed to act as Her Majesty's Commissioners to inquire into the practice of subjecting live animals to experiments for scientific purposes, and to consider and report what measures, if any, it may be desirable to take in respect of any such practice: Viscount Cardwell, Lord Wimmarleigh, the Right Hon. W. E. Foster, M.P.; Sir J. B. Karslake, M.P.; Mr. T. H. Huxley, Professor of Natural History in the Royal School of Mines; Mr. John Eric Erichsen, and Mr. Richard Holt Hutton.

Reviews and Notices of Books.

THESES UPON THE NERVOUS SYSTEM, at the recent Concours of the École de Médecine de Paris. DR. R. LÉPINE ON LOCALIZATION IN CEREBRAL DISEASES.

This most interesting subject fell to the lot of Dr. Lépine, and has been treated by him in a very clever manner. His thesis is skilfully constructed and successfully condensed. The first chapter is taken up by a study of the main points in cerebral anatomy, by a review of recent successful localizations of functions by physiologists in the cerebral cortex, the cerebral peduncles, the sensorial centres, the corpora striata, optic thalami, and the corpora quadrigemina. In addition to the proof afforded by physiological experiment (Fritsch and Hitzig, Ferrier), pathological evidence in support of these localizations is brought forward in the shape of cases, some of the most striking of which are new and original. In this manner are studied the seats of lesions which may give rise to spasm (or palsy) in the facial muscles, in the face and arm, in the whole of one side of the body; those which may produce hemi-anæsthesia, with or without affection of special senses; those producing hemipopia, aphasia, crossed paralysis. Dr. Lépine inclines to the classic idea of the mode of decussation of fibres in the optic chiasm. A lesion of the radiating white fibres a little outside of the thalamus opticus will produce hemi-anæsthesia, with participation of higher senses; if the lesion be lower down, upon or in the posterior part of the crus cerebri, common sensibility will alone be lost. In aphasia, lesion of the third (posterior) frontal convolution (of left side in right-handed people) is necessary.

In a second chapter the physiological and pathological data previously discussed are used to lay the foundation for the diagnosis of the seat of a cerebral lesion. In an appendix Dr. L. briefly reviews the possible localization of functional disorders, epilepsy, hysteria, chorea, migraine, insanity. A detailed bibliography relating to the anatomy and physiology of the brain, with extracts of important cases by other authors, closes the book. A plate is appended containing three figures, one representing the brain of the chimpanzee in profile, with Ferrier's centres for movements of hands, face, lips, legs, marked upon it; another is a profile view of the human brain, showing by means of dots the seat of localized lesions in three cases, by Dr. Charcot and the author, one case by Hitzig, and one by Wernher; the third figure exhibits seat of lesion just outside of thalamus opticus, having produced hemi-anæsthesia and hemi-chorea during life. Dr. Lépine's thesis is honorably characterized by just reference to German and English authorities; Hitzig and Ferrier are given their full share of credit, and J. Hughlings Jackson is shown to have preceded them both by pathological observations upon the cortex cerebri. We congratulate Dr. Lépine upon his thesis, and upon his success in obtaining the position of *professeur agrégé*.

ORTHOPEEDIA; OR, A PRACTICAL TREATISE ON THE ABERRATIONS OF THE HUMAN FORM. By JAMES KNIGHT, M.D., Physician and Surgeon in Charge of the Hospital of the New York Society for the Relief of the Ruptured and Crippled, etc. Published by G. P. PUTNAM'S SONS, New York. 1874.

The book before us is an account of the plan of practice pursued in the treatment of deformities at the hospital of which the author is physician and surgeon in

charge. He tells us in his introductory remarks, "that the subject-matter of this book may be considered as the varied and consolidated experience of many practitioners, modified by our own judgment."

All through the volume we find quite long quotations from the works of English surgeons, but they are one-sided, and do not express the real opinion of the authors in question. We fail to see the name of a single American surgeon, except the late Dr. Mott. Our author does not seem to find anything worth "modifying" on this side of the Atlantic.

The book begins with some "Remarks on Defective Physical Formation," then some chapters on Deformities of the Feet—Infantile Paralysis. In speaking of the latter, no notice is taken of any recent investigation in regard to its pathology. The author seems to be under the impression that no advances have been made in that branch for the last twenty years. He devotes fifty pages to the consideration of "Electricity as a Therapeutic Agent," with some remarks on galvanic cautery, the bearing of which on "orthopædia" we fail to see. Chapters on Lateral Curvature of the Spine, Rachitis, Hernia, Procidencia Uteri, etc., follow. He then makes some remarks on the pathology of disease of joints. In regard to that of the hip-joints he says, "that it is only in the *third* stage that we have the bones actually diseased," and "that in the *first* and *second* stage, the disease is mainly limited to the surrounding tissues, tending to indolent abscess, etc."

In regard to treatment, he places a roller around the joint over cotton batting, and allows the patient to go about. He regards the weight and pulley as only palliative, not curative, but actually injurious treatment, and states "that no such kind of treatment is *permitted* in this institution." In a chapter on Necrosis he says, "that the violence done to the recuperative process by splitting, sawing, and chiselling for the purpose of removing the sequestrum of decaying bone, often arrests normal tendency to cure, and impairs vitality to the extent of a necessity for amputation, which seldom saves life"!!

It is almost useless to add that he is no advocate of excision of joints.

He devotes a short space to caries of the spine, and concludes the book with a chapter on tonics and their effect on the system.

He does not give any statistics as to the frequency in which the different kinds of deformity were found, nor does he give us any account of the result obtained from the plan of treatment he has pursued.

We had marked many other passages in the book which are as open to criticism as those we have noticed, but the above show the peculiar views in regard to pathology and treatment held by our author.

We are sorry that we cannot find anything to recommend in the book. There is a want of a good work on deformities, thoroughly up with the times. Not written for the purpose of impressing the profession that the author alone is competent to treat this class of diseases, but one written *for* the profession. Such a book will be welcomed by all, but we cannot see what benefit is to be gained by the multiplication of books like the one we have been considering.

PHYSICIANS' OFFICE CASE-RECORD AND PRESCRIPTION BLANK BOOK;

PHYSICIANS' POCKET CASE-RECORD PRESCRIPTION BLANK;

MEDICAL CHART OF TEMPERATURE, PULSE, RESPIRATION AND REGIONS.

The Case-Record Company, of 224 Laurel Street, Cincinnati, O., have issued the above very convenient

set of blanks for the use of physicians. The first and second differ mainly in size, and afford means for keeping, in the form of a "stub," copies of prescriptions and memoranda of the prominent features of each case. The Medical Chart is of foolscap size; one side of the sheet is ruled and arranged for the history of a case, to facilitate which a blank form heads the page. The opposite side of the sheet has an excellently arranged blank for recording the phenomena usually observed, and four outline figures of the thoracic and abdominal regions.

JAHRESBERICHT ÜBER DIE WIRKSAMKEIT DER AUGENKLINIK, von Dr. H. SCHOELER, Docent an der Universität zu Berlin, im Jahre 1874. Berlin, 1875.

This brief report gives us the annual record of the eye clinic once presided over by Von Graefe, and later by Evers.

A grand total of 4,102 out-door patients were treated; 460 were received into the institution, and 366 major operations were performed. Cataracts to the number of 52 were removed by Graefe's method. Experiments were made on a number of cataract patients, in whom the results of the operation were very successful, to determine, by the aid of special apparatus, whether there was any accommodative power in an eye after the removal of the lens. Dr. Schoeler thinks he has demonstrated conclusively that there is no accommodation in a lensless eye.

Among the operations on the ocular muscles is the unique case of an advancement of the inferior rectus. The patient was 65 years of age; the right eye was blind from separation of the retina and consecutive cataract, and in the left there was a high degree of paresis of the inferior rectus, consequent on an injury received by the patient during childhood. The eye was drawn up to such a degree that the pupil was covered by the upper lid. Tenotomy of the superior rectus gave but little relief. After the advancement of the inferior rectus the pupil was so far recovered as to give the patient very useful vision.

MEDICAL VOCABULARY. Intended specially as a Book of Reference for the Student. By R. G. MAYNE, M.D., LL.D., Author of "An Expository Lexicon of Scientific Terms," and J. MAYNE, M.D., LL.R.C.S. Edin., L.S.A., Author of "A Dispensary," "Toxicologia," etc. Fourth Edition, revised and enlarged. Philadelphia: Lindsay & Blakiston. 1875.

This little volume, containing 459 pages, claims upon its title-page to be the bearer of explanations for "all terms and phrases used in the various departments of medical science and practice," etc., etc. One of the authors, in the preface, states without qualification that it has been the aim, in preparing this work, to keep pace with the "more and more scientific, more amalgamated and complex state the science of medicine is getting into every year," and how well the task has been performed we shall presently see.

The general arrangement and typography of the book are very good, and give the reader quite an extended account of the terms which have been introduced. When the book, however, is more closely examined it is found to be sadly deficient in words with which the modern medical student constantly meets, and this, notwithstanding the fact that the authors somewhat sneeringly deprecate the deficiency manifest in "much larger volumes." The first word we sought for in this "accessible key" was hyperplasia. Certainly this word is used frequently enough to entitle it to a place in this pretentious volume, but it has no abiding-place here. *Hyperopsia* is on duty, it is true, and by the aid of that we went on, but in vain did we search for

typhlitis, peri-typhlitis, cyphosis, urosacin, neuroglia, myelin, etc., etc., words which are in common use among medical men, and should be found in a book that has been "revised and readjusted, items of recent date introduced, and redundancies withdrawn." It seems to us at least that this work could have been made far more valuable than it is, by omitting such redundancies as gasterangemphraxis (said to mean congestion of the blood-vessels of the stomach), hypohæmia (deficiency of blood), locodochium (lying-in hospital), hyalodecresis (escape of a part of the vitreous humor), with many others, and introducing terms more nearly within the common medical student.

The definitions also of very many of the more common terms which have been introduced are exceedingly unsatisfactory. For example, the term cirrhosis is given as a name for certain conditions of the *kidney only*; apoplexy is defined to be a "sudden arrest of sense and motion;" and death is spoken of as "real, not apparent death, but extinction of bodily life," etc., etc. We trust that these references are sufficient to give the reader an idea of what was contemplated by the authors of this book, also an idea of what has been accomplished, and we will therefore leave the subject by asking him to make his own inferences.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 9, 1875.

DR. FRANCIS DELAFIELD, PRESIDENT, in the Chair.

FIBROMA OF THE BREAST.

DR. FINNELL presented a tumor about the size of a hen's egg, that had been removed from the breast of an unmarried woman, twenty-five years of age. About seven years ago she noticed a small nodule in the organ just at the edge of the nipple, which gradually enlarged and elongated until finally a pedicle was formed about three inches in length. The tumor was not vascular, but was nourished by an artery of considerable size. It was painless, and gave the patient no special inconvenience, but during the last year had grown quite rapidly. From the size of the artery it was thought that the tumor would have grown much larger had it not been removed. When removed, a ligature was first placed upon the pedicle, and the operation was performed without hemorrhage. The length of the pedicle was one of the peculiar features of the growth. It presented a beautiful cauliflower specimen.

DR. DRAPER inquired of Dr. Delafield if the tumor did not present an unusual appearance for a fibroid growth.

DR. DELAFIELD remarked that it did not present an unusual appearance for that variety of fibroid. Such pendulous tumors of the skin are really hypertrophies of the skin as much as anything, like large warts, and might, perhaps, with propriety be called papilloma, but at the same time they contain more or less of connective, and sometimes mucous tissue.

CHRONIC HEART DISEASE—ANEURISM OF THE CAROTID.

DR. W. H. DRAPER presented a specimen of cardiac disease and aneurism of the carotid artery removed from the body of a man æt. 36 years, who died at Roosevelt Hospital, June 9, 1875. The specimen was

accompanied by the following history, prepared by the house-physician :

Thomas Dullart, *æt.* 36, Ireland, married, hackman. Admitted May 13, 1875.

Family history good.

Patient has never been an athlete, has always been a hard worker, but never had work that caused sudden exertion.

Ten months ago he noticed a lump on the left side of his neck, which pulsated, but never caused him any pain or any alarm.

With the exception of this lump he was perfectly well up to six months ago, when he caught cold and had a little cough; great dyspnoea and pain over the epigastrium and præcordium.

At this time his voice began to change, being sharper in pitch, and he had a feeling as though something was pressing on the trachea.

These symptoms steadily increased, and he also suffered severe pain over the left chest in front.

The pain extended to the right shoulder, and over the right chest anteriorly; has never had any pain behind.

The pulsating tumor in the neck grew rapidly, and became painful when pressed on by the overlying muscles.

There is no history of renal or hepatic trouble.

Present condition: well nourished; appetite poor; tongue clean; bowels constipated; pulse 120; temp., 98½° F.

Urine acid; 1018; albumen 15%; oxalate lime.

May 14.—Examined by Dr. W. H. Thomson.

Very loud bruit under both scapulae behind, especially under inferior angle of right. Bronchial respiration over right lung posteriorly. Murmur best heard at the root of the right innominate, of an aneurismal character, heard as low as the right nipple. Intercostal pulsation down to the right nipple.

Apex beat one and one-half inches to left of left nipple, in seventh intercostal space one and a half inches below left nipple.

Diagnosis.—Aneurism at the juncture of the innominate and aorta, dislocating the heart to the left.

May 17.—There is an aneurism of the left carotid, which is increasing rapidly in size; the pulsation can be controlled by pressure on the artery below the tumor.

May 20.—Patient has been growing anasarctous for the past few days, his legs, abdomen, and arms are involved. Complains of great dyspnoea and pains.

May 30.—Edema has increased to an enormous extent, and causes great discomfort. Over the left thigh and leg there has spread an erythematous redness, which is glistening and very painful.

June 6.—Examined by Dr. W. H. Draper.

Auscultation.—Respiratory murmur and vocal resonance cease at the inferior angle of the right scapula. Moist râles over the left side posteriorly. Feeble respiration below the angle of the scapula.

Apex beat five inches to left. Loud systolic murmur heard best to the left of left nipple in sixth intercostal space; also distinct in the second intercostal space, one and a half inches to the left of median line. Heart dulness extends to one inch to left of left nipple.

No swelling above sternum, in sternal notch; no pulsation; no thrill.

Diagnosis.—Aneurismal expansion of the arch of the aorta. Aortic and mitral regurgitation.

Ventricular hypertrophy and dilatation.

June 8.—Dyspnoea increasing; patient becoming cyanotic.

June 9.—Died at 7 A.M.

Autopsy made by Dr. Francis Delafield twelve hours after death.

Brain.—Not examined.

Heart.—Two pounds. Both ventricles dilated and hypertrophied; aortic and mitral valves atheromatous, thick and short; endocardium of left ventricles below mitral valves much thickened; aorta atheromatous, not dilated.

Aneurism size of pigeon's egg of left common carotid just below bifurcation.

Lungs.—Right pleura two-thirds full of serum, recent fibrin. Left pleura one-fourth full of serum.

Lungs pigment induration.

Liver.—Small—nutmeg.

Stomach.—Congested, and coated with mucus.

Kidneys.—Large, hard, smooth.

Spleen.—Large and firm.

DR. DRAPER remarked that this specimen presented considerable interest clinically, for here was a man who first noticed a pulsating tumor upon the neck ten months ago, and upon close examination gave no subjective symptoms of cardiac disease prior to that time. At that time there was no dyspnoea upon exertion, or other symptoms referable to the heart. Six months ago he began to suffer from dyspnoea and other evidences of obstructed circulation through the lungs, but the symptoms then, it was thought, indicated the development of some disease of an aortic rather than of cardiac character, and the objective symptoms also seemed to point in that direction. When, however, Dr. Draper examined the patient, June 6th, from the general anasarca, he was impressed with the idea that the patient was in the last stages of cardiac disease, and of a mitral character. Physical examination also seemed to point to that condition rather than to aneurism. There were evidences of extreme obstruction to the venous circulation; there was fluid in the serous cavities, and at the same time there was no pressure upon the trachea and œsophagus, and for these reasons he was inclined to doubt the existence of an aortic aneurism, and upon examination no thrill nor bruit was detected. The post-mortem reveals simple valvular disease of the heart, with marked hypertrophy, and a carotid aneurism. There is also a moderate dilatation of the aorta, which, perhaps, would have passed unnoticed had he not been impressed with the idea that an aneurismal dilatation would be found when post-mortem was made.

CARCINOMA OF THE BREAST.

DR. W. H. B. POST exhibited a mammary gland removed sixteen days previously from an unmarried woman, aged forty years. Her menses ceased about one year ago. About fourteen months ago she received a blow upon the breast from a heavy iron bar, which was followed by considerable inflammation. This soon subsided, however, and a short time afterwards she noticed a small tumor, about the size of a marble, upon the sternal edge of the mamma, which remained almost stationary for six months. At the end of that time it began to increase in size rapidly, and when of the size of a hen's egg an operation for its removal was advised, but declined by the patient. About one month ago the patient desired the operation, but it was disapproved of for two reasons: (1) because the skin had become so closely adherent to the tumor; and (2) because the axillary glands had become involved. The woman, however, insisted upon having the operation performed; and after consultation with Dr. A. C. Post it was decided to undertake it. For several months previous to the removal of the breast the patient had suffered extreme pain, and was almost unable to take

nourishment. Sixteen days after the operation the pulse is at 104, has not been above 110, and the wound is nearly filled with granulations. The wound left was about eight inches in length in one direction, and about six inches in the other, and is a large, open, granulating surface.

She takes nourishment and medicine well, and suffers no pain. According to a suggestion of Dr. Atlee the patient is taking Fowler's solution in small doses, which will be continued for at least one year.

There was no hereditary history of cancer. Microscopical examination had not been made.

Dr. DELAFIELD remarked that a peculiarity of the tumor was the hypertrophied condition of the skin seen at different places.

Dr. A. C. POST remarked that while the operation was being performed the universal adhesion of the skin to the tumor, as well as its great induration, attracted special attention.

NECROSIS OF THE LOWER JAW.

Dr. A. C. POST presented a specimen of dead bone removed, June 5th, from the lower jaw of a child nine years old. The disease of the jaw had presented itself without any obvious cause. The mother of the child regarded it as the result of toothache, and it was probable that inflammation of the periosteum extended from the affected tooth. A portion of dead bone was found projecting through the gums, and was removed with a pair of strong forceps. Several forming teeth were involved in the disease. As is the case ordinarily when necrosis of the lower jaw occurs, there was a large amount of involucrum formed. When the disease affects the upper jaw, as a rule, scarcely any involucrum is formed.

CARDIAC HYPERTROPHY—CHRONIC BRIGHT'S DISEASE—THICKENED PLEURA—HEMORRHAGE INTO THE PLEURAL CAVITY.

Dr. J. H. POOLEY exhibited the thickened pleura, the kidney, and the heart, removed from the body of a patient who died in the St. John's Riverside Hospital, June 8th. The patient was a remarkably large and powerful man. He gave a history of specific disease, and had been addicted to the use of alcohol for years. He had also suffered from several attacks of ascites and general dropsy.

Autopsy twelve hours after death.

Rigor mortis well marked. Body emaciated. Considerable serum in the abdominal cavity. Liver fatty. Right kidney atrophied; surface made irregular by deep depressions, giving the organ a lobulated appearance. Left kidney increased in size and somewhat lobulated.

There was a large accumulation of serum in the left pleural cavity. The heart was dislocated, and considerably hypertrophied, but there was no marked evidence of valvular lesions, although the aorta and all the large arteries of the body were atheromatous. The pleura of the right chest was thickened to a most extraordinary extent, was firmly adherent to the costal surface, and exhibited distinct indentations made by the ribs. The lower portion of the right pleural cavity contained a large loose reticulated clot of blood, which had compressed the lung to a considerable extent. The source of the hemorrhage was not found.

There were evidences of recent meningitis.

Dr. DRAPER inquired if any articular enlargements were present.

Dr. POOLEY replied in the negative.

Dr. KNAPP remarked that the thickened pleura had

an appearance as though composed of smooth muscular fibres.

Dr. POOLEY raised the question as to the probable explanation of the hemorrhage into the right pleural cavity, which was, perhaps, the immediate cause of death.

Dr. DELAFIELD remarked: "Might not the hemorrhage have come from the new blood-vessels in the thickened pleura? There must be new vessels in the new layer of tissue which had been formed, and it is the case, sometimes, that such thickened pleuras are composed almost entirely of blood-vessels. This man, it seems, had a condition of the heart which favored a constant state of venous congestion, which, together with the vascularity of the new pleural membrane, could explain the hemorrhage.

"With regard to the peculiar appearance of the kidneys, concerning which Dr. Pooley has made inquiry, the deep depressions are probably the result of cicatricial contraction, due to the existence of old infarctions at these points. There are evidences of quite a recent infarction in one kidney, and the condition of heart present is one favorable to the development of such a condition. There is, in addition, evidence of chronic Bright's disease."

Dr. FINNELL remarked that one kidney might be said to be hypertrophied, while the other was atrophied, or, if you choose, cirrhotic.

Dr. DELAFIELD remarked that in a certain sense that was true.

Dr. A. C. POST remarked: "Is it not probable that as one kidney became atrophied, the other became increased in size to supplement it?"

Dr. DELAFIELD remarked that it might be so, but that it was difficult to say how much the change depended upon such a condition in cases of chronic Bright's disease.

Dr. DELAFIELD asked Dr. Heitzmann what his explanation would be for the condition of kidney seen in this case.

Dr. HEITZMANN replied that he regarded the deep depressions and elevations as characteristic of atrophy secondary to croupous nephritis.

Dr. DELAFIELD did not think the atrophy secondary to any form of chronic Bright's disease could produce such deep cicatricial depressions as seen here. Such changes made the nodular kidney, but they do not give rise to the deep depressions.

Dr. HEITZMANN remarked that he did not wish to exclude infarctions from the problem, but that he had seen such condition as was present in these kidneys, the result of secondary atrophy, following pure croupous nephritis.

EPITHELIOMA OF THE CONJUNCTIVA.

Dr. KNAPP presented a specimen of epithelioma of the conjunctiva, removed from the eye of a colored woman about thirty years of age. When eight or nine years old she suffered from violent inflammation of both eyes, but from this she entirely recovered. About three months before coming under observation she received a blow upon the eye, which was followed by violent inflammation, and since that time the eye has steadily increased in size. When first seen the eyeball had a swollen appearance, and the lids were held apart by a fleshy-looking, easily-bleeding mass, which protruded through the palpebral fissure. The cornea was not perceptible, and the conjunctiva could be reached only by forcible exposure of the outer and upper portion of the globe. The posterior limit of the globe could be made out, and the tumor was evidently attached to the eyeball near its equator. The conjunc-

tiva of the lids were healthy, and the posterior portion of the globe offered some resistance to the touch.

The ordinary operation of enucleation was performed, and the posterior part of the globe was found in a perfectly healthy condition. The wound healed without the slightest reaction. The eyeball itself showed a portion of detached retina, which stretched across the vitreous and attached itself to the anterior portion of the globe. The cornea had disappeared for about two-thirds its extent, and at one point there was a perforation through which the choroid prolapsed. Whether the perforation was the result of the injury or of ulceration of the cornea, he was unable to say, but regarded it as the probable result of the injury, for the reason that there was but little change in the tissue of the iris. Upon the sclerotic and upon the cornea there was located a consistent pseudoplasm which started distinctly from the epithelium of the sclerotic. Upon microscopical examination the bulk of the tumor was found to be composed of epithelial cells cemented together without any intervening substance, presenting the same appearance seen in the outer layers of the skin. In some places the epithelial cells were grouped. In some places there were seen the same kind of nuclei as seen in the epithelial cells, imbedded in a more or less granular matrix, representing the structure of the rete Malpighii. In no place was fibrous tissue found. It was a true epithelioma. The operation was performed four months ago, and to all appearance the patient is perfectly well. How long perfect recovery may remain was simply conjectural, but he regarded the prognosis as favorable. An interesting feature of the case was its evident traumatic origin.

DR. DELAFIELD inquired if no stroma at all was found in the tumor.

DR. KNAPP answered that there was none. In the places where the nuclei were imbedded in a homogeneous granular mass, more or less of blood-vessels were found.

DR. DELAFIELD inquired if he would call the tumor an epithelioma when it consists simply of an accumulation of epithelial cells.

DR. KNAPP answered in the affirmative.

DR. DELAFIELD remarked that a simple accumulation of epithelial cells constituted a wart, while in an epithelioma there is a stroma and more or less of blood-vessels.

The Society then went into executive session.

Correspondence.

HOMEOPATHY IN OUR MEDICAL SCHOOLS.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Any one who has had occasion to see much of the literature of the sect of homœopaths cannot have failed to be impressed with the fact that next to the fallacy of their theory of cure, as a sufficient basis for a system of medical practice, their characteristic is a woful ignorance of matters which may be classed among the essentials of a knowledge of medicine. Excepting a few individuals who have obtained their education in medicine at regular and respectable antipathic schools, most of this class of physicians are educated in and obtain their degrees from schools in which the teachers are either half-educated men, who are no more competent to give correct instruction in their several branches from

knowledge which they possess of the subjects than any one of the majority of second-course students in our best schools would be, or else they are men of fair capacity, who, as a means of securing patronage, profess to adopt homœopathy as a system of practice, while in truth their practice belies their professions.

If it is true that the religious belief of a mother determines, in the majority of instances, that of her children, notwithstanding the fact that teachers of other creeds and forms of worship abound in every community and are to be listened to almost daily, is it strange that, in commencing the study of medicine—which has no authorized instructors of the public—young men, who have no other means of knowing the differences between, or value of, therapeutical theories than such as are available to the general public, should be influenced by homœopathic associations and relationships, and by the statements which are constantly appearing in the secular and religious papers complimentary of the liberality and scientific advancement of this sect, and directing attention to the success of its members in practice? It is not to be doubted that a considerable number of young men enter homœopathic schools in the honest belief that in so doing they are taking all right and proper measures for acquiring a good knowledge of the science and art which they intend to practise.

To suppose, however, that all these men pursue the course on which they have set out, is a mistake, as I know from several instances to the contrary. Indeed, an article appeared not long ago in THE MEDICAL RECORD, showing, by statements copied from an English homœopathic journal, that in Great Britain the control is lost of the professional course of their young men, as they become advanced in their studies, to the extent that it has been found difficult to find competent men to fill vacancies occurring in the resident staffs of the hospitals and dispensaries which it has cost the homœopaths so much trouble and expense to establish.

That the standard of qualification for a degree must be very low in the homœopathic schools of this country, I think no one can doubt who looks over the books and journals which are current among them, or considers the quality of the men who compose their faculties. That this standard is likely to be raised by the schools themselves is not very probable when such antipathic schools as we have among us are open to the suspicion of obtaining large classes by maintaining low standards of qualification.

In view of the condition of affairs which I have described, and which I believe to exist, I can see no occasion to regret the action of the Board of Regents of the University of Michigan.* I believe that the establishment of the homœopathic branch of this school will meet with quite as much opposition from homœopathic schools and their sympathizers as it has previously received from the friends of the Ann Arbor school, for the very reason that the low fees, the prestige of the University diploma, and the establishment of a hospital will tend to lessen the patronage of these other schools.

In no other institution in the country could the union have been effected with so favorable a prospect of a triumph for legitimate medicine. This is one of the only two schools we possess where any preliminary qualifications are required and the salaries of the professors are to any extent independent of the size of the class, and one of the very few in which the manner of

* This letter was written before our correspondent had an opportunity for seeing Prof. Dunster's correction in our last issue.—L.D.

conducting the examinations is open to inspection. The attendance on lectures and clinics other than those given in the homœopathic department cannot fail to insure for the homœopathic matriculants as thorough a knowledge of the fundamental branches of medicine and surgery as has for years been acquired by the students in this department of the University. With so good an opportunity to insure a thorough acquaintance with these branches the "homœopathic" professors are welcome to teach them as much or as little as they please about the action of remedies. That is a subject about which the best of us know too little to make us very sure of our ground in a discussion. Let us have the opportunity of teaching them to make a correct diagnosis, and their patients are not very likely to suffer at their hands in the way of treatment. As to what will be the effect upon their future course in practice, after the homœopathic students have been brought into contact with the professors of the "mixed faculty," I have too high an opinion of the character of the present faculty to entertain any doubt, providing they attend strictly to teaching their several branches and leave the "homœopathic faculty" to take care of its own interests and questions.

Already homœopaths appreciate the situation, and are either declaring the plan proposed to be unjust, insisting upon a distinct school in which they can teach homœopathic anatomy, chemistry, and physiology, and homœopathic surgery, obstetrics, and jurisprudence, or are calling for the utmost circumspection in the choice of the two men who are to bear the responsibility of the success or failure of the scheme which they have so long striven to accomplish, and which, having been achieved, places them in a worse plight than before. While the plan of a homœopathic chair in the faculty was vigorously opposed they grew eloquent over their supposed wrongs, and gained a sort of reputation as martyrs in a noble cause. Now that they have all that they confess they are entitled to, let us see what they will do about it. The harm that is likely to result from the introduction of two more votes into the faculty I fail to appreciate. As to the establishment of an entirely independent homœopathic school, I think we have reason to remonstrate. We have altogether too many already for the good of science.

INDEX.

CONTAGIOUSNESS OF DIPHTHERIA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—A few cases of diphtheria have recently occurred in my practice which strongly illustrate the contagious power of this fearful disease.

In one family there occurred five cases, four of which proved fatal to children with the respective ages of two, five, seven, and nine years, contracted on this wise: A brother, aged eleven years, visited the family of his uncle, in which the disease was present in one member of the family. The visit was prolonged but a single day. Three days after returning home, he was seized with sore throat, with the characteristic exudation, and successively, in periods of from two to three days, the remaining children of the family, except a nursing babe, were attacked. The mother borrowed a shawl to wear to the funeral of the child which last died, and after the funeral returned it to a sister living about two miles distant. There was no communication between the families during the sickness, except this transaction. *No visiting between the families.* In three days after the shawl was returned, two children belonging to the family from which the

shawl was borrowed, and to which it was returned, fell sick of diphtheria and died.

The mother of the first children rode about two miles in an open sleigh in company with a young lady who sat on the same seat with her. About four days after this ride, the young lady fell sick with the same disease, and communicated it to her mother, who acted as her nurse. Again, the same mother of the first-named children, about two weeks after the death of her last child, visited a brother's family, and remained several days in an adjoining town. The brother's wife took diphtheria within four days of her departure, and barely escaped with her life. Previous to these cases there had been not a single one of diphtheria for at least six miles, for the space of time extending over a year. These cases must have been communicated in the way indicated, and bear to my mind, on careful investigation, the relation of cause and effect, and strongly illustrate to me that diphtheria is not only contagious, but that infection may be produced not only by contact with infected persons, but may be communicated by healthy persons who have had care of the sick, and also transported to some distance by means of wearing apparel.

DAVID DANA SPEAR, M.D.

FREEPORT, ME.

New Instrument.

SELF-RETAINING NASAL SPECULUM.

By DR. D. H. GOODWILLIE,

NEW YORK CITY.

THE above cut represents a three-armed spring nasal speculum, made for me by P. H. Schmidt, Broadway and Thirty-fourth Street, and has these advantages: that it makes a good distention of the nostril in different directions; it is light, and can be retained in the nostril without the necessity of holding it.

It gives very little inconvenience to the patient. My most favorite way of using it is in the horizontal position, as the wing of the nostril is well distended by the middle arm, and is also easily retained.

160 WEST 24TH STREET.

ARMY AND NAVY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from July 18th to July 24th, 1875.

The following-named Assistant Surgeons (recently appointed) will report as follows for assignment to duty:—

TAYLOR, BLAIR D., in person to the Superintendent U. S. Military Academy, West Point, N. Y., for temporary duty.

WORTHINGTON, J. CH., by letter to the Commanding General, Military Division of the Atlantic.

COMEGYS, E. T., by letter to the Commanding General, Military Division of the Atlantic.

REED, W., in person to the Commanding Officer, Willet's Point, N. Y. Harbor, for temporary duty at that post.

KILBOURNE, H. S., by letter to the Commanding General, Department of the Missouri.

MERRILL, J. C., in person to the Superintendent Mounted Recruiting Service, for temporary duty at St. Louis Barracks, Mo.

HALL, W. R., by letter to the Commanding General, Military Division of the Atlantic.

BARNETT, R., by letter to the Commanding General, Department of the Gulf.

TORNEY, GEO. H., in person to the Commanding General, Military Division of the Atlantic, for temporary duty.

CRAMPTON, L. W., by letter to the Commanding General, Department of the Gulf.

WOOD, M. W., in person to the Commanding General, Department of the Platte.

TAYLOR, M. E., by letter to the Commanding General, Department of the Gulf.

NEWLANDS, WM. L., by letter to the Commanding General, Department of California.

SMITH, R. E., by letter to the Commanding General, Department of the Missouri.

SHANNON, WM. C., by letter to the Commanding General, Military Division of the Atlantic.

TESSON, L. S., by letter to the Commanding General, Department of the Missouri.

SPENCER, WM. G., by letter to the Commanding General, Department of the South.

ROSSON, R. L., by letter to the Commanding General, Military Division of the Atlantic. S. O. 147, c. s., A. G. O.

AINSWORTH, F. C., Assistant Surgeon.—To report to the Commanding General, Department of the Columbia, for assignment to duty. S. O. 147, A. G. O., July 20, 1875.

BROWN, P. R., Assistant Surgeon.—To report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O., 147, c. s., A. G. O.

PORTER, JAS. Y., Assistant Surgeon.—Assigned to duty with troops temporarily encamped at Indian Key, Florida. S. O. 127, Department of the Gulf, July 13, 1875.

NAVY.

July 20th.

WHITING, ROBERT, Assistant Surgeon.—Ordered to the Receiving Ship *Potomac*.

SIEGFRIED, CHARLES A., Assistant Surgeon.—Detached from the *Richmond*, South Pacific Station, and ordered to return home and report his arrival.

PERSONS, R. C., Assistant Surgeon.—Detached from the Storeship *Onward*, South Pacific Station, and ordered to return home and report his arrival.

HEFFINGER, A. C., Assistant Surgeon.—Detached from the Receiving Ship *Sabine*, and ordered to the Storeship *Onward*, at Callao.

AMES, HOWARD E., Assistant Surgeon.—Detached from the Receiving Ship *Potomac*, and ordered to the *Richmond*.

July 25th.

AMBLER, JAMES M., Assistant Surgeon.—Detached from the *Kansas*, and ordered home to await orders.

Medical Items and News.

REMOVAL OF THE LARYNX.—The case, reported a short time since, in which Prof. Billroth, of Vienna, removed the larynx, is still familiar to our readers. Prof. Bottini, of Novara, has performed a similar operation, which is reported in *Gaz. Med. di Torino*, No. 10, 1875. The patient is a healthy young man, who, on account of dyspnoea, had already had laryngotomy and cauterization of the larynx performed. The operation for removal lasted an hour and a half, and left the patient much exhausted. He was, however, much revived by injections of beef-tea and wine. Examination of the larynx showed that it was quite obstructed by a grayish-red tumor. In spite of an attack of erysipelas and a series of abscesses, the man gradually improved, gained the power of deglutition, and was able to cough, breathe, and sleep well. The wound has healed up, and the ease, save future accidents, may be looked upon as successful.

DR. FLEETWOOD CHURCHILL has, in consequence of failing health, retired from the practice of medicine and obstetrics. He has presented his valuable obstetrical library to the King and Queen's College of Physicians, and has received from the College an address expressive of its thanks for his liberality and for the valuable service he has rendered them as President and Professor in the school. His portrait is to be placed in the College hall.

"THE BRITISH MEDICAL DEFENCE ASSOCIATION" is the title of a new society which is being organized against the encroachment of irregular practitioners in England.

M. HENRI ROGER, who has been physician to the Hôpital des Enfants of Paris, since 1851, and by the law which limits the service of physicians to fifteen years has arrived at the end of his term of office, has been presented by his students and former *internes* with a medal commemorative of their regard and the success of his teaching.

DR. SAGER, one of the oldest members of the faculty of the Ann Arbor School, has resigned the Professorship of Obstetrics and Diseases of Women.

THE CANADIAN MEDICAL ASSOCIATION is to hold its annual meeting at Halifax, Nova Scotia, on Wednesday, the 4th of August. A large delegation from the American Medical Association is expected. Dr. David, of Montreal, is the General Secretary of the Association.

DR. CHARLES GOWAN, formerly Assistant-Superintendent of the Worcester Asylum, in England, has been appointed Medical Superintendent of the Toronto Lunatic Asylum.

CHANGE IN THE ORGANIZATION OF THE MEDICAL DEPARTMENT OF THE FRENCH ARMY.—It is reported that the French military hospitals, both field and garrison, are to be removed from the control of the line and placed under the direct management of the medical staff, subject only to the orders of the commanding general.

RUSH MEDICAL COLLEGE, of Chicago, is reported to have effected a permanent union with the Chicago University, and will hereafter be known as the medical department of that institution.

HARVARD MEDICAL SCHOOL.—Thirty graduates of this school received diplomas at the commencement of the University, on the 30th of June.

INDIANAPOLIS has started a County Medical Society.

Original Communications.

DIPHTHERIA OF THE CONJUNCTIVA.

By ROBERT SATTLER, M.D.,

RESIDENT ASSIST. SURGEON, OPHTHALMIC AND SURGICAL INSTITUTE,
N. Y.

WITHIN the last few months a number of patients have presented themselves at the clinics of the Ophthalmic and Aural Institute, suffering from conjunctivitis diphtherica, the disease assuming somewhat of an epidemic character. The comparatively infrequent occurrence of this disease in America has been a sufficient inducement for the publication of some of the cases, and for a review of the clinical history and literature of conjunctivitis diphtherica.

Diphtheritic conjunctivitis is of frequent occurrence in Germany, especially in the northern part. In some of the cities, particularly Berlin, the disease has repeatedly assumed the character of an epidemic. In Berlin, epidemics were described by v. Graefe and Hirschberg in 1852-54, and also in 1866-70; commonly in the spring and autumn months. A small epidemic is reported by Horner, of Zurich, in 1869. During a period of five years, Jacobson, of Königsberg, observed, among 10,000 eye patients, 40 cases of sporadic and 22 cases of epidemic diphtheritic conjunctivitis. In Switzerland, Belgium, England, France, Russia, and America, only isolated cases have occurred, and the disease has never assumed the character of an epidemic.

Wells, in his book on the "Diseases of the Eye," speaks of the extreme rarity of the disease in England. Wecker, of Paris, says that the grave form of diphtheritic conjunctivitis is seldom met with in France. In Vienna the disease is said never to assume its typical character.

Diphtheritic conjunctivitis usually develops acutely in most of the cases. It occurs as 1, an idiopathic affection of the conjunctiva, or as 2, a complication of other affections of the conjunctival membrane (catarrhal and trachomatous conjunctivitis), or 3, it complicates diphtheritic affections of the pharynx or larynx, which, however, happens very rarely.

In the cases enumerated below, the disease occurred as a complication in 4 cases; in 2 cases the disease manifested itself without any antecedent ocular trouble or constitutional affection. In one of the last cases, the history was obtained from the brother, who stated that the patient, for several days before the disease manifested itself, was permitted to play with a child affected with diphtheritic sore throat, and that this child had frequent attacks of violent coughing.

The disease seems to attack children more frequently than adults, and occurs as frequently as an affection of one eye as of both. Those of a scrofulous or tainted constitution, and especially those suffering or having suffered from antecedent ocular trouble, dependent upon a constitutional taint, are more prone to this disease. The disease may limit itself to certain portions of the conjunctiva, or it may involve the entire conjunctival membrane.

Several varieties or forms of the disease have been described by Von Graefe and Hirschberg. The latter mentions three varieties:

1. The disseminate or partial form.
2. The confluent form.
3. The diffuse form. (Von Graefe has described this as the confluent.)

The disease may be commonly divided into four stages: 1. An initiatory or catarrhal stage, which,

however, is not always present, and if present is generally of short duration; 2. The stage of deposition and diphtheritic infiltration; 3. Blennorrhœal; and 4. The stage of cicatrization.

The disease usually commences abruptly with marked and rapidly progressing swelling, and a feeling of heaviness and stiffness of the eyelids. The lids are excessively painful to pressure. The local temperature is generally very decidedly increased. On opening the eyelids a thin, hot, yellowish fluid exudes. These symptoms become rapidly more pronounced, the disease often reaching its maximum intensity in the course of one or two days.

The swelling of the eyelids, as the disease advances, becomes more tense and harder, and excessively hot and painful. The cutaneous surface presents a stretched and shining appearance. The discharge is moderate, as compared with a case of acute blennorrhœa. Every attempt to open the lids is followed by a gush of thin yellowish fluid containing flocculi.

On examination of the conjunctiva, in the commencement, it will generally be found that the diseased process commences in some portion of the conjunctiva tarsi, and there limits itself, or it extends over the fornix to the conjunctiva of the sclerotic, thus infiltrating the conjunctival membrane in its totality, and even overlapping the cornea to a certain extent. The diseased conjunctiva, instead of presenting its natural pale red color, now is pale white or yellowish, the result of an infiltration of a fibrinous product in the sub-epithelial, tunica propria, and sub-conjunctival layers. The conjunctiva is more or less elevated or thickened; its surface is very finely granular. At different points it presents a drawn-in or puckered appearance. The color of the diseased conjunctiva varies from a pale yellowish to a blanched or glistening white.

As the disease advances, the swelling of the lids becomes more and more tense, red, and painful. The chemosis of the ocular conjunctiva becomes more pronounced, it often encircling the cornea like a hard and unyielding wall. The discharge also increases; it is straw-colored, and contains more flocculi. Constitutional disturbance usually is present at this time, if it has not manifested itself before. There is an increased bodily temperature, the thermometer ranging from 100° to $103\frac{1}{2}^{\circ}$, accompanied by the usual symptoms of fever, anorexia, malaise, prostration, etc., etc.

After the disease has existed from four to eight or nine days, the transition into the third or blennorrhœal stage takes place. The swelling, redness, and tenderness of the lids diminishes. The external surface of the lid has lost its tense and glossy appearance, and the eyelids are soft and wrinkled. The thin flocculent discharge changes into a creamy pus. On examination of the eyelids, they are more readily everted, and the diseased conjunctival surface is now changed: it is no longer white and shining, but red and somewhat irregular. At the places of the white and somewhat raised infiltration we see ulcers, with an irregular base and ragged outline, the result of the necrosis of the tissue. Conjunctival hemorrhages are now apt to occur.

In the conjunctiva tarsi, deep cicatrices most frequently result. The scars which form in this locality leave more unfavorable consequences (entropion, trichiasis, etc.) than those occurring in the fornix or lower lid.

The third or blennorrhœal stage varies in duration from two to eight or ten weeks, a partial relapse often taking place in this stage.

The fourth, or stage of cicatrization, is also of variable duration, and the boundary line between it and the third stage is not sharply defined. In this stage

of the disease cicatrization goes on, and cicatrices of greater or less extent and depth result. Often the cicatrices, especially in children, are superficial and of no considerable depth, escaping observation in many cases. The cicatrices, as before stated, are generally confined to the tarsal conjunctiva of the upper lid, serious deformities of the lid resulting in many cases.

Complications of the cornea may occur at any stage of the disease, assuming the character of central and marginal ulcerations. The most destructive and rapidly progressing corneal complications are met with in the second stage of the disease.

Complication of the cornea manifests itself by objective and subjective symptoms.

A slight circumscribed and uniform haziness of the cornea appears, usually in its central portion, or it may occur at the margin or at any part of the cornea; in some cases the whole cornea becomes uniformly hazy and infiltrated.

When this condition is once present, its course is generally rapid. The ulcerative process advances rapidly and leads to partial or total destruction of the cornea. When the destructive process reaches the membrana Descemet, the ulceration is in some cases temporarily arrested; this layer bulges, and the centre of the ulcer now presents a shining or bead-like appearance, after which perforation almost invariably follows. Corneal complications in this stage (second) almost inevitably result in perforation.

The central ulcers are commonly deep and circumscribed, whereas the peripheral ulcers are more superficial and extensive.

Corneal complications occurring in the third stage are much less destructive and less rapid in their course, the ulceration much resembling the corneal complication in conjunctivitis blennorrhœica. In the last stage (cicatrization) corneal complications are rare, and if they occur, are dependent on the mechanical irritation of the cicatrices.

Mention is made by Saemisch of an implication of the lower lid, the inflammation there assuming a diphtheritic character and resulting in the formation of abscesses. He ascribes this in part to a propagation of the diphtheritic process of the conjunctiva, and in part also to the corroding effect of the secretions, from the constant contact of the mucous membrane of the swollen and pendent upper lid with the outer marginal portion of the lower lid. A peculiar diffuse inflammation of the cellular tissue of both upper and lower lids was observed in one of the cases mentioned below; small superficial abscesses resulting near the marginal portion of the lid.

Conjunctivitis diphtheritica must be considered as highly contagious. It was observed (v. Graefe) that the secretion from a case of blennorrhœa developed the disease. In one of the present number of cases, the child C. P., the disease evidently originated as a result of the direct conveyance of a detached portion of the diphtheritic product from a child suffering from diphtheritic sore throat, during an attack of coughing.

In a certain number of cases conjunctivitis diphtheritica is developed in persons suffering from constitutional disease, or diphtheria of the larynx or pharynx; whereas, in other cases, it occurs solely as a local or independent affection of the conjunctiva, or as a complication of chronic affections of the conjunctiva, in scrofulous or tainted subjects.

The prognosis in all cases of diphtheritic conjunctivitis is grave; depending on the extent of conjunctiva involved, rapidity of progress, early corneal complications, age and constitution, and the hygienic sur-

roundings of the patient. Where the cornea is affected early in the disease, the prognosis is almost invariably bad.

V. Graefe observed 9 total destructions of the eyeball among 40 cases affected with the disease. Hirschberg, among 94 cases; 34 cases proved fatal, and 54 resulted in recovery.

Treatment.—Before mention is made of the treatment recommended by various authorities, I will briefly mention the treatment pursued in the cases enumerated below, which consisted mainly in local and also general measures, viz., placing the patient under the most favorable hygienic and dietetic influences possible.

Local measures.—When one eye was affected, the other was hermetically closed. In children this was found frequently impracticable, and was therefore abandoned. In adults it was invariably practised, where one eye was still unaffected.

Ice compresses were constantly applied, and the most scrupulous cleanliness observed. The eyes were cleansed every ten minutes with lukewarm water, to which a small quantity of salt had been added; the salt relieved the irritant effect which even the lukewarm water would produce.

After the blennorrhœal stage had set in, the cautious application of argentum nitr. was commenced. Corneal complications were treated with atropia.

The treatment of diphtheritic conjunctivitis, owing to the extreme danger of the disease, has engaged the attention and study of many prominent oculists. The use of strong solutions of argentum nitr. in the second stage is universally condemned, on the same ground that it is injurious in all fibrinous and croupous exudations of other mucous membranes. A strict antiphlogistic treatment in the form of constant ice compresses is thought, and has clinically proven to be the most efficacious method. Ice applications are well borne by almost all patients.

Local abstraction of blood has been strongly recommended by von Graefe. He applied a number of leeches to the nose and temporal region.

Scarification of the healthy portion of the affected conjunctiva has been practised; this latter plan has, however, been abandoned, for the disease would frequently propagate itself to the incisions made.

Arteriotomy, or division of the outer commissure, has been recommended. This is certainly of value in lessening the pressure of the swollen eyelids upon the globe; but here also the danger exists of a diphtheritic infiltration of the lips of the wound. If the disease is only partial and the diseased process confined to the central portion of the conjunctiva tarsi, there is less danger, and here the performance of the operation may be considered warrantable.

Mercury has been strongly recommended (v. Graefe and others). Jacobson substituted, the application of moist warmth, where cold compresses were not tolerated by the patient. Bertin mentions a case where it was thought to hasten the appearance of the blennorrhœal stage, by cauterization; but this is considered an extremely dangerous and unwarrantable proceeding.

Ice applications, frequent and absolute cleanliness, and placing the patient under the most favorable hygienic and dietetic influences, comprise the chief and most beneficial remedial measures.

In illustration of the above, I will briefly mention the following cases:

CASE I.—*Diffuse form, both eyes, resulting in a small leucoma adherens of left eye and almost complete leucoma of right eye.*

J. J., æt. 17 (under care of Dr. H. Knapp), was ad-

mitted to the Ophthalmological and Aural Institute, March 1st, 1875. He was treated as an outdoor patient for acute conjunctivitis, for about two weeks prior to his admission, and was improving rapidly until yesterday, when his condition suddenly changed for the worse. The left eye became first affected; a feeling of stiffness and heaviness of the lids supervened, followed by swelling, which rapidly progressed, attended by severe pain and tenderness.

Several hours after the left, the right eye also became affected. During the night the symptoms became more pronounced; the lids were stiff and unyielding, and excessively painful. Symptoms on admission: Eyelids enormously swollen, hot, and painful. On opening the lids, a quantity of thin, dirty yellowish fluid escapes. The conjunctival surface is found to be pale and somewhat elevated. Both corneae are surrounded by a ring of chemotic conjunctiva, but they are yet not involved. Ice compresses were ordered to be applied constantly, and frequent cleansing with lukewarm water.

March 2d.—Patient complains of intense pain; lids more swollen; cutaneous surface stretched and glossy. The infiltration of the conjunctiva is more pronounced; the surface is elevated and puckered, and it has changed from the pale to a dull yellowish white color. There are large, irregular, confluent patches of infiltration, commencing near the margin of the lower lid, and extending in some places as far as the lower portion of the conjunctiva bulbi.

In the right eye the diseased process is more marked. Here the infiltration involves the entire tarsal conjunctiva, and extends over the fornix to the ocular conjunctiva. The chemosis is hard and unyielding. The left cornea is clear, but the right is somewhat hazy at its centre. The ice applications were continued, and a small quantity of salt was added to the warm water, in order to relieve its intensely burning effect.

March 4th.—The pain and swelling of the lids have both diminished; the infiltration of the conjunctiva has advanced in both eyes, until almost the entire tract is involved in the diseased process. The right cornea is more extensively infiltrated than the left, though the latter has a central superficial ulcer.

March 6th.—Eyelids less rigid, softer, and redder; the discharge is profuse and purulent. The left cornea has perforated; the ulcer in the right is more extensive, and the marginal infiltration advances rapidly, the centre of the ulcer being raised, and the periphery depressed, while a little above the centre a shining transparent point is seen—evidently the membrane of Descemet. The pain is excessive; marked constitutional disturbance, with fever and decided prostration, is present.

March 9th.—No pain, but patient feeble and prostrated. The ulcer of the right has perforated, and the cornea is extensively sloughing. The ocular chemosis has diminished; the conjunctival surface is very red and swollen. The grayish-white infiltration has disappeared, leaving irregular erosions or excavations in the tissue, varying in extent and depth.

March 13th.—General condition better; the conjunctiva is very red, and the surface is roughly granulated or ragged. The ulcer of the left cornea is cicatrizing, the anterior chamber is partially restored, and the pupil dilates. In the right eye, the iris having prolapsed, it was to-day snipped off with the scissors. The ice compresses had been used up to this time from the first, and to-day the use of argt. nit. was commenced, in addition to the previous treatment.

March 30th.—The patient had a relapse. The lids became again swollen, red, and painful; the discharge,

which was profuse, assumed the character of thick pus; the surface of the conjunctiva appeared quite red, and covered with villous projections, but there was no appearance of infiltration. A slight superficial ulceration commenced upon the seat of the old ulcer, in the left eye, the whole cornea being hazy, while the right cornea was infiltrated and vascular at the margin and near the points of ulceration. Ice continued.

Upon April 5th the patient's condition was improved—the swelling had in a great measure subsided, the discharge had decreased, the left cornea had begun to clear up again, and the pupil could be seen to dilate. The right cornea was still quite vascular and infiltrated, except at its lower and inner portion, which was clear.

Upon April 30th the conjunctival inflammation had almost completely disappeared; upon the left cornea, a little internal to its centre, a leucoma adherens was left, while the rest of the cornea was clear; the anterior chamber was established, and the vision had begun to improve rapidly.

The right cornea was still more involved—a leucoma covering all except its lower and internal portion. In this condition the patient was discharged.

CASE II.—Diffuse form, affecting both eyes; sloughing of cornea (left); escape of lens; phthisis bulbi; right eye recovery.

II. II., *et.* 2½ years—care of Dr. Pooley; has been a patient at the clinic for two weeks, suffering from severe blennorrhœal conjunctivitis of the left eye. To-day (April 10th) the symptoms are decidedly aggravated. The lids are markedly swollen and stiff; the cutaneous surface stretched and shining; the upper lid overhanging the lower in a massive fold. The local temperature is elevated; the discharge, instead of being blennorrhœal in character, is thin and straw-colored, containing flocculi. The palpebral conjunctiva is extensively infiltrated; the surface puckered, and of a grayish-white color; and the cornea is surrounded by a firm ring of chemosis, so that it is not distinctly visible. An ulcer of considerable depth, with a clear and elevated base, exists in the lower and outer quadrant of the cornea.

Although there is little or no constitutional disturbance, the general health of the patient cannot be called good. The treatment consisted in ice applications, together with the constant cleansing of the eye with warm water, to which was added a little salt.

Upon April 11th the swelling of the lids is somewhat diminished, but the cornea has perforated, and is infiltrated throughout. The infiltration of the conjunctiva and subconjunctival tissue is more marked. This morning injection and redness of the healthy eye began, although the greatest caution was observed. In the course of six hours the disease became fairly developed. The lids are stiff, swollen, and excessively painful. In the tarsal conjunctiva of the upper lid infiltration is already observed, and the surface is pale and irregular. The same treatment was immediately begun for this eye.

April 14th.—Swelling and rigidity of the lids very pronounced. The infiltration involves nearly the entire palpebral conjunctiva of both eyes, the surface presenting the characteristic grayish color and puckered appearance. The ocular chemosis is marked in both eyes.

April 17th.—Blennorrhœal stage fairly begun. The lids have lost their swollen, stiff, and stretched appearance, and the discharge is of a thick, creamy pus. The lids are more readily everted; the conjunctiva is red and swollen, being deeply excavated at some points, and at others covered with large trachomatous projec-

tions. The left cornea remained clear while the right rapidly sloughed, and the lens became evacuated.

April 20th.—In addition to the ice applications the use of a weak solution of argent. nit. was commenced. The swelling and rigidity of the lids is daily decreasing. The chemosis is less.

May 2d.—Doing well; general physical condition yet feeble, and some swelling of the lids still exists, but the conjunctiva is becoming smooth, having lost its ragged appearance.

May 9th.—The treatment has been continued, and the symptoms are now rapidly subsiding, leaving the right cornea clear, but the left eye has resulted in a complete phthisis bulbi.

CASE III.—*Confluent form, affecting the left eye; ulceration and perforation cornea; central staphyloma.*

S. P., *et.* 2 years (care Dr. H. Knapp).

The patient, a poorly-nourished and unhealthy child, was first seen on Feb. 12th, 1875.

It was stated that the eye became affected two days previous, and yesterday the lids became very decidedly swollen, rigid, and painful. In the same house in which the case resided there was a child sick with diphtheritic sore throat, with whom this one was in the habit of playing.

Stat. presens—left eye. Eyelids present a shining red and stretched appearance, and are rigid and painful. A thin, hot, yellowish discharge bursts forth upon opening the lids. The conjunctival surface is dull and yellowish white. Infiltration extends over the entire tarsus and fornix, as far as to the ocular conjunctiva, which is hard and chemotic. The cornea is slightly infiltrated at its margin. The treatment in this case also consisted in ice applications, together with frequent cleansing, as in the others. In the course of the next few days the swelling and stiffness of the lids, and the ocular chemosis became more pronounced, as well as the appearance of the constitutional disturbance. The directions with regard to treatment were evidently not observed by the parents, for in about ten days afterwards the patient was again brought to the clinic, with the disease advanced to the blennorrhœal stage, and the cornea perforated and infiltrated throughout, while the conjunctiva was very vascular, presenting numerous large and some smaller villous projections. The discharge at this time was profuse and purulent.

In the course of the next few weeks the disease advanced toward recovery, but the cornea had so far sloughed as to result finally in a central staphyloma.

April 10th.—Swelling of lids all gone; cornea opaque and staphylomatous; conjunctiva tarsi covered with deep cicatrices; general health improving.

CASE IV.—*Disseminate form; recovery.*

K. W.—, *et.* 6 years (care of Dr. Knapp), was brought to the clinic Feb. 11th, 1875. The father stated that the child's eye had suddenly become inflamed yesterday. Since then the symptoms have become rapidly pronounced.

Stat. pres.—r. e. Marked swelling and stiffness of the eyelids, with severe pain upon opening; profuse, thin, yellowish discharge. The conjunctival surface of the lower lid is of a dull, yellowish color, especially marked near the margin. The conjunctiva of the upper lid is pale; no infiltration, however, exists. The ocular conjunctiva is faintly swollen; cornea clear.

Constant ice applications were ordered, and frequent cleansing of the eye with water.

Feb. 18th.—The ice applications were faithfully made.

The disease has now advanced into the blennorrhœal stage; the swelling and stiffness of the lids have diminished; the discharge is thick and purulent. On the third day the cornea became hazy in its lower and outer portion; it did not, however, take on ulcerative inflammation. The diphtheritic infiltration also extended to the conjunctiva tarsi, but only in circumscribed patches.

Feb. 20th.—Eyelids soft and wrinkled, copious purulent discharge: the conjunctival surface presents a vascular and succulent appearance; the cornea is clear; the ocular chemosis is disappearing. The cold applications were continued, together with the daily use of a weak solution of argt. nit.

April 8th.—Lids normal, conjunctival surface still red, several small cicatrices in the upper tarsal region.

CASE V.—*Confluent form, occurring in a trachomatous eye after an entropion operation; sloughing of cornea; total staphyloma.*

March 5th.—Patient has suffered from trachoma for a number of months. Her general health has not been good. About seven days previous to her admission she was operated upon by Dr. Pooley for entropion of right eye. The inflammatory reaction following the operation was unusually severe, so that on account of the swelling and pain several of the sutures had to be removed. In the course of the next day the pain and swelling of the lids became more pronounced. On entering the institution she presented about the following symptoms, in addition to those mentioned above: The palpebral conjunctiva of the lower lid is raised, and is of a grayish-white color; the ocular conjunctiva also faintly swollen; the cornea is opaque and infiltrated, but on the cutaneous surface the wound made by the operation remained perfectly healthy. As in the above cases the treatment consisted in the application of ice and cleanliness by means of lukewarm water. The left eye, which as yet was not affected, was hermetically closed.

March 7th.—Eyelids stiff, rigid, and excessively painful; discharge thin and flocculent; chemosis very marked; cornea sloughed and perforated, and the infiltration of the conjunctiva almost complete.

From March 8th to 11th the pain and rigidity of the lids gradually diminished; the external wound cicatrized slowly, having at no time taken on diphtheritic inflammation; the discharge was profuse and purulent, but the conjunctival surface was red and swollen, and marked by large irregular erosions, which bled quite freely upon being touched.

It should here be remarked that at the beginning of the blennorrhœal stage, hemorrhage from the conjunctiva was quite frequent, and in some of the cases very profuse.

April 1st.—The cold compresses have been kept up, and for the past few days varied with the application of argent. nit. in weak solution. Although the conjunctiva is still granular, it does not show such deep erosions, but is beginning to approach a normal condition.

May 1st.—Swelling of lids has disappeared; the conjunctiva still red and somewhat swollen; cornea staphylomatous; patient discharged.

CASE VI.—B. M., *et.* three years (care of Dr. Pooley); a strumous unhealthy child; has been treated at the clinic for three weeks for phlyctenular conjunctivitis.

Has had frequent attacks of sore throat and eruptions about the face and head during the past year. On April 14th it was brought to the clinic, after an

absence of four days, with a decided change in the symptoms. Eyelids rigid, hot, painful; conjunctiva of upper lid raised and discolored; that of the lower lid marked by several small circumscribed patches, between which the membrane is red and swollen. The chemosis is great, and the cornea is hazy and infiltrated, and the usual thin discharge is present. The same treatment was adopted in this case and the other eye carefully guarded against inoculation.

Upon April 19th the blennorrhoeal stage set in, the stretched and rigid condition of the lids began to abate, and the ocular chemosis began to subside, but the cornea had perforated, leaving opacity and infiltration through its entire structure. Palpebral conjunctiva rough and granular, and very red.

May 1st.—Inflammatory symptoms have in a great measure subsided. The conjunctiva, though red, is not rough and granular as before; the cornea is opaque.

THE HYPODERMIC USE OF APOMORPHIA AS AN EMETIC IN CHILDREN.

By WM. F. DUNCAN, M.D.,

NURSERY HOSPITAL, RANDALL'S ISLAND, N. Y.

A GREAT deal has been written about the hydrochlorate of apomorphia, since its discovery in 1868, in foreign journals of medicine; but until very recently it has attracted little notice in this country, where its use at the present time is restricted to only a few members of the profession. I obtained a specimen of this drug several months ago, and have ever since been using it whenever occasion has demanded an emetic, and now believe that, in this capacity, its value cannot be too highly estimated. It acts more rapidly and certainly, and efficiently as the best of the older emetics, considering them to be turpeth mineral, tartar emetic, and ipecac.

The qualities which recommend it particularly are:

1. The rapidity of its action; 2, the absence of danger from an over-dose; 3, the lightness of its secondary effects; 4, the shortness of the period of nausea; 5, the easy manner of its introduction.

The average time at which emesis has occurred, after its introduction under the skin, is 2.9 minutes, which is very much less than the shortest time noticed when using the yellow sulphate of mercury.

The longest time for emesis to appear was 4.15 minutes in a case of alcoholism, while the shortest was 1.75 minutes in a case of capillary bronchitis.

That this feature is one to be appreciated there is no gainsaying by any who has ever witnessed the relief produced by vomiting, in children with croup or capillary bronchitis. While in cases of poisoning, from the introduction of any of the corrosive poisons into the stomach, this gain of several minutes would be incalculably valuable.

In speaking of the absence of danger from an over-dose of apomorphia, reference is made to the use of the English preparation of the drug which is entirely pure, and not to the German, which, according to reputation, contains an impurity of morphia.

But having given gr. $\frac{1}{3}$ to a child of six years, without detecting any symptoms of the effect of opium, I feel free to express the belief that danger from this source is not to be apprehended.

Again, since any pronounced action is limited to the production of vomiting, as no symptoms of gastro-duodenitis, nor disturbance of the cerebral functions, nor any of those of the depression frequently witnessed after the exhibition of other powerful emetics, are no-

ticed, one feels safe in its administration. The entire visible effect of the drug disappears after the lapse of an hour or an hour and a half, and the child's system does not seem to have been disturbed by it.

That there are other effects than emesis is recognized, such as a tendency to sleep, a slight weakness of the legs, yawning, etc., but they are very slight and soon disappear after vomiting ceases.

In the introduction of apomorphia the shortening of the period of nausea and retching is a great boon to children, who are spared several minutes of agony; for in three cases out of five, no change in the child's face, indicating nausea, can be seen until with one great effort the entire contents of the stomach are ejected.

The hypodermic method of using this drug makes it applicable to many cases in which an emetic could not otherwise be exhibited, for children at times absolutely refuse to swallow any medicine, and can be compelled to take it only after a long, exhausting struggle, which usually results in the loss of much of their strength.

Again, its superiority in this respect would be very marked in cases of poisoning, where the substance in the stomach might cause a chemical change of the drug introduced into that organ.

The dose of apomorphia, hypodermically used, for an adult, ranges from gr. $\frac{1}{10}$ – $\frac{1}{20}$, but in children it is quite large in proportion.

For a child of 18 months.....	gr. $\frac{1}{16}$.
“ “ 2 years	gr. $\frac{1}{16}$.
“ “ 3 “	gr. $\frac{1}{8}$.
“ “ 3½ “	gr. $\frac{1}{8}$.
“ “ 5 “	gr. $\frac{1}{4}$.
“ “ 8 “	gr. $\frac{1}{2}$.

Glycerine seems to preserve the strength of the drug, and alcohol will dissolve it more readily than water, so that I recommend it to be prepared after the following formula:

R. Apomorphiæ.....	gr. vii.
Spts. rectificat.....	℥xx.
Glycerin.....	℥x.
Aque.....	℥i.
M.	

In a child of two years, $\frac{1}{3}$ of a grain may be used.

EPITHELIAL CANCER OF OESOPHAGUS.

By E. BRADLEY, M.D.,

NEW YORK.

T. L., born in England, of a very long-lived family, in June, 1867, noticed a difficulty in swallowing, which continued with increased severity until death. During the last three months of his illness he could not swallow solids, but was able to swallow fluids until within two minutes of his death. There was no pain, no swelling or external evidence of disease. He gradually grew weaker, and life terminated by inanition. Autopsy, twenty-four hours after death, revealed the fact that three and a half inches of the posterior surface of the tracheal rings, extending from the cricoid cartilage downwards, together with the corresponding portion of the oesophagus, had slowly sloughed away. There was slight thickening behind the arytenoid cartilage; no sign of any sac about trachea or oesophagus; nothing intervened between the anterior rings of the trachea and the muscular coverings of the spinal column. No fluids had accumulated in the diseased neighborhood nor in the thorax.

The disease proved to be epithelial cancer of the œsophagus, ulcerating into the trachea. The most singular and remarkable feature in this case was the fact that he drank and swallowed beef-tea until within a few moments of his death, and that he did not die of strangulation. The fact that epithelial cancer should attack the œsophagus, gives additional importance to the case. Gibbes mentions but two instances, and all authorities agree that prolonged deglutition is remarkable and very unusual in analogous cases.

CYST OF THE THYROID GLAND CURED BY ELECTROLYSIS AFTER INJECTIONS HAD FAILED.

By ANDREW H. SMITH, M.D.,

NEW YORK.

Miss M. S., aged twenty-four, applied for treatment at the Throat Department of the Manhattan Eye and Ear Hospital in January last, the case being one of a tumor of the size of a small orange, situated in the right thyroid region. The growth was first observed some four years before as a small lump, since which time it had gradually but steadily increased in size, until it now constitutes a very decided deformity.

The patient has taken a great deal of iodine, and a variety of applications have been employed locally by the advice of her family physician, but without benefit.

On examination, the tumor is found to be globular, smooth, and elastic, and is evidently a cyst containing fluid. The anterior segment of its wall lies immediately under the skin, to which it is not adherent. The posterior segment, on the other hand, appears to be intimately blended with the underlying tissues. The tumor follows the movements of the trachea in swallowing.

The cyst was evacuated by means of the impromptu aspirator which I have described in a former number of THE RECORD. Two ounces of fluid were drawn off, a little darker in color than brown sherry, and filled with shining particles which the microscope showed to be crystals of cholesterine. The fluid was solidified completely by boiling.

Half a drachm of tincture of iodine was injected into the sac, and this operation was repeated about twice a week, after the plan recommended by Stoerck. But the cyst always filled again in the course of forty-eight hours, and at the end of a month no real progress had been made. I therefore abandoned the injections, and resorted to galvano-puncture. A common glover's needle was thrust into the cyst, and connected with the negative pole of a Drescher's constant-current battery. The other pole was connected with a sponge held in the hand. From twelve to twenty cells were employed, and the sittings occupied from ten to twenty minutes. Three sittings sufficed to render the tumor perfectly hard and somewhat nodular, and after this there was a rapid decrease in size. Twelve sittings, occupying about six weeks, reduced the growth to a small, irregular mass of hardened tissue, which could be felt beneath the skin, but which caused a scarcely perceptible prominence. Treatment was then suspended, and when I last saw the patient, a month later, absorption was still going on, with every prospect of ultimately removing every trace of the tumor. A minute circular cicatrix showed the location of each puncture.

Dr. GEORGE B. OWENS, J.P., has been nominated Lord Mayor of Dublin for 1876.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND PECULIARITIES OF TREATMENT.

CARCINOMA OF FEMALE BREAST.

THERE are certain points in the following case which are interesting from the fact that they are not of very frequent occurrence.

A female patient, æt. seventy-five years, with good family history, had always enjoyed excellent health until about two years ago, when she noticed a lump on the left breast, round, hard, and about the size of a walnut. She could not assign any cause for its appearance, had not received a blow or other injury, and her attention was first attracted to it by an itching sensation. This lump soon began to give her great pain, began to increase in size, and the breast was removed by the knife. The wound healed kindly, and the patient had no further trouble until about one year ago, when she noticed a small lump on the other breast, almost identical in shape, size, and situation with the one developed in the first breast. The second tumor increased in size rather rapidly until it reached the present appearance. The entire gland was involved, the axillary portion rather firmly attached to the subjacent muscles, and ulcerative action had just begun, but the discharge was only very slight. There were several little nodules in the integument, at a little distance from the main portion of the disease. Another feature of interest consisted in the fact that, although the right breast was so extensively involved by the disease, yet the axillary glands upon the same side remained unaffected as far as could be determined by external examination, while the axillary glands upon the opposite side were enlarged, extremely tender to the touch, and gave rise to some pain. One of these tumors was globular in shape and about two inches in diameter, and had been observed only two weeks. The condition of the patient was unusually good, in view of her age and the disease from which she was suffering.

This case was interesting in the following respects:

First. As a case of scirrhus occurring in a patient at such an advanced age.

Second. As a case of scirrhus recurring in the opposite breast. Recurrence of the disease usually takes place either in the cicatrix or axillary glands upon the same side from which a breast has been removed.

Third. Notwithstanding the extensive amount of disease present in the remaining breast, the axillary glands of that side remained unaffected, while the axillary glands upon the left side were extensively involved.

Fourth. There was nothing in the appearance of the patient which indicated the presence of the so-called cancerous cachexia.

Fifth. The old cicatrix was movable and presented a perfectly healthy appearance.

Sixth. The nipple was not retracted, although the entire gland was involved, and ulceration had commenced.

The question of treatment remained to be considered. In view of the age of the patient, her comparatively comfortable condition, more or less adhesion of the diseased gland to the subjacent tissues, some involvement of the integument, and manifestations of the disease in the axillary glands upon the opposite side, it was considered inappropriate to resort to operative in-

terference, unless the patient desired it, in which case both masses of the disease must necessarily be removed.

TYPHOID FEVER.

A case of the above illustrated the fact that the temperature does not always follow a definite course in this disease. It has been held that the temperature in typhoid pursues a course which is peculiar to that disease and not seen in any other, and this may be true; but that there are many cases of true typhoid fever in which the temperature does not pursue a regular course, is probably equally true. When the temperature table shows a record that agrees with what is called the "characteristic course," it becomes a very strong symptom, but the absence of such a tracing does not necessarily exclude the presence of the fever.

In this patient the morning and evening variation usually seen in typhoid fever was absent. He was a man forty-eight years of age, and when admitted to the hospital his temperature was $102\frac{1}{2}^{\circ}$ F.

On the 15th (next morning), $102\frac{1}{4}^{\circ}$; evening, $102\frac{1}{2}^{\circ}$.

On the 16th, morning, 101° ; evening, 102° .

On the 17th, morning, 100° ; evening, 100° .

Patient delirious.

On the 18th, morning, $101\frac{1}{2}^{\circ}$. The temperature throughout the case presented no peculiarities other than noticed. His attack came on gradually, and in the first week two symptoms were present which are prominent in this affection, namely, epistaxis and diarrhoea. He also had the eruption and tympanites.

AMPUTATIONS—STUMPS TREATED AS OPEN WOUNDS.

In one of the surgical wards a goodly number of stumps were seen. Stumps of three legs and one thigh in the upper third were particularly noticed, which were entirely healed. Of late all stumps in this division have been treated open, and not a single fatal result has occurred during the last six months. It was the opinion of the visiting surgeon that had they not been treated in this manner many of the patients would have certainly died. In some of the cases extensive sloughing took place, and in one necrosis, and it was believed that the open treatment was the only thing which not only modified the diseased action in these, but prevented it in others.

COLLODION.

This article is sometimes used to secure the coapted edges of small wounds. It is very commonly applied with a brush, one coating after another, the surgeon meanwhile blowing upon the surface to assist the process of drying, and it is almost certain to drop off in flakes within a few days when so applied. Bring the edges of the wound nicely in contact, and while they are held, apply all the collodion necessary with a single daub from a loaded brush. In this way quite a firm dry suture is obtained, and one which will remain in place for a considerable length of time.

MAMMARY ABSCESS.

The following is a very simple plan of treatment, and it is claimed that it is much more satisfactory than strapping the breast with adhesive plaster, counter openings, injecting the sinuses with iodine, etc., all of which measures have been extensively resorted to, especially in the country.

What the surgeon desires to do in these cases is to evacuate the abscess thoroughly, at the same time to press the walls of the abscess together, and then retain them in contact. These are substantially the indications to be met, so far as local measures are concerned,

for, if the two surfaces can be held thoroughly in contact during forty-eight hours, granulations will spring up which will unite them, and the abscess will be closed.

The plan of treatment recommended meets all these indications and accomplishes the desired results without giving rise to pain, but on the contrary those who had the dressing applied said that it was rather pleasant. It is a plan of dressing within the reach of any practitioner, and can be applied to any breast, no matter how tender. It affords gentle, but firm pressure, and holds the walls of the abscess in contact until union takes place.

Take a piece of coarse sponge, large enough to cover the breast, and about four inches thick; make it a trifle concave or cup-shaped upon one surface, thoroughly cleanse it in boiling water, being very careful to remove all particles of sand, and, while wet, place it between two pieces of board and subject it to at least fifty pounds pressure. At the end of twenty-hours it will be dry and ready for use.

First cover the breast with a moderately thick layer of oakum, which readily absorbs the pus, and at the same time has an antiseptic influence.

Coarse lint may be used, but it is not nearly as pervious to pus as is the oakum, and must be watched more closely, lest free discharge from the abscess is prevented by it. It is important to get the breast up and support it, and this is done by raising it with the hand, before applying the sponge. It is then retained in position by applying the bandage, which is to hold the sponge in place, sufficiently tight, and in the proper direction to accomplish this purpose.

Always leave the upper edge of the sponge uncovered, so that it can be easily wet, for it is almost impossible to wet the sponge through several thicknesses of a tightly-applied muslin roller. The dressing should not be removed for two or three days, and then another sponge should be immediately applied, and thus the dressing kept up for at least eight or ten days, in order to be certain that the surfaces of the abscess are firmly united. The question arises whether this dressing should be applied when there is considerable milk in the breast. There need be no hesitation upon this point, for the milk is readily taken care of by the absorbents, and does no harm. A single sponge may be wet two or three times before its elasticity will be expended, and then it is necessary to make the second application.

ERYSIPELAS.

Injections of carbolic acid hypodermically at the margin of the erysipelatous blush have been used with considerable success in arresting the spread of the inflammation. But such injections cannot, for obvious reasons, be used about the scalp, the ears, etc.

As a substitute, therefore, the following has been suggested, and tried in one case with signal success:

℞ Carbolic acid..... 1 part.
Oleic acid..... 8 parts.

M.

The method of application was insisted upon. It should be constantly applied for six or eight hours, and this can be done by dipping the finger in the preparation and then rubbing the parts over for two or three minutes, and repeating it every ten or fifteen minutes.

THE LONDON MEDICAL RECORD, with its issue of July 15th, is changed from a weekly to a monthly publication.

ROOSEVELT HOSPITAL.

DR. HEINEMANN, HOUSE-PHYSICIAN.

ACUTE ARTICULAR RHEUMATISM—IMMINENT DEATH—
COLD PACK—COLD BATH—RECOVERY.

THERE are a few points in the history of the following case which are worthy of special note: (1) delirium and rise in temperature, accompanied with a subsidence of local symptoms; (2) failure with the pack, but success with the bath in controlling high temperature, etc.

A young man, *æt.* 18, previously healthy, but rather intemperate, was admitted to the hospital while suffering from his first attack of acute rheumatism, affecting several joints. T. 102° Fah.

He was placed in bed, and received quin. sulph. gr. vi. t.i.d., and hypodermic injections of $\frac{1}{12}$ of a grain of sulphate of atropia, three times a day.

His disease progressed favorably for three days, when he began to be a little delirious. Thinking perhaps the atropia might be the cause of this, it was discontinued, and Rochelle salts were substituted.

The delirium, however, did not decrease, but his temperature began to rise, and soon reached 103°. At night of the same day it was 104°; the next morning, 104°—evening, 104½°; following morning, 104½°—evening, 106½°. The delirium at this time was very active, and subsultus was present to such an extent as to render it impossible to count the pulse. The patient was immediately placed in the cold pack, and remained there one hour; at the end of which time his temperature was 107°. He was then removed from the pack, and at once placed in the cold bath—having a temperature of 80° and gradually lowered to 60°—and kept in ten minutes, when his temperature stood at 99½°. At the end of two and a half hours it had risen again to 105°, when he was placed in the bath a second time, and kept there until his symptoms—partial subsidence of delirium, etc.—indicated a return towards the normal standard.

It was found necessary to repeat the bath at intervals of about two hours, keeping him in from five to ten minutes, in order to hold his temperature within reasonable limits, and they were continued in this way for nearly thirty-six hours. Subsequently repetition was necessary only every three or four hours, and at the end of forty-eight hours his temperature fell to 103°, and remained.

When the subsultus had subsided sufficiently, the pulse was found to be 160°.

The patient struggled violently when placed in the bath the first time, but only three or four had been given when he seemed to enjoy them, and before his temperature was permanently brought down he asked for the water. While the high temperature was present and the baths were being given, infusion of digitalis was also administered in drachm doses every two hours, but this was discontinued as soon as the heat was permanently reduced, and three ounces of whiskey every three hours were substituted. When the delirium and the high temperature appeared, there was a general subsidence of all local symptoms, but these have returned to a certain extent since the temperature has remained below 103°.

To-day his pulse is 86 and regular; his appetite is good; he sleeps well, and is getting whiskey, three ounces every four hours, and quinine. When admitted a systolic murmur was present, and it still remains. There could be no question but that the cold bath saved the life of the man.

ANEURISM OF AORTA.

One point of interest in these cases related to an item of treatment. There were two patients suffering from this affection, and one had an aneurism of the left carotid artery in addition. Both suffered considerably from dyspnoea and pain; and for the relief of these symptoms dry cups and leeches had been applied.

It has been considered improbable that the application of two or three leeches over the præcordial region can afford relief in these cases, but such seems to be the clinical fact, for these patients said that they experienced a very great change for the better by the application.

Two leeches over the præcordial region, and dry cups between the scapulae were applied on alternate days.

ASTHMATIC MIXTURE.

The following asthmatic mixture is much used in this hospital:

Hoffman's anodyne..... ʒ i.
Tr. belladonna..... gtt. xv.
Potass. iodid..... gr. v. M.

S. One t.i.d.

It sometimes happens that the iodide gives rise to nausea; if so, it is dropped from the prescription.

CHRONIC BRIGHT'S DISEASE.

A favorite pill with a visiting physician, to be used in the general treatment of this affection, consists of

℞ Hydrarg. bichlorid..... gr. ʒv.
Quinia sulph.,
Digitalis pulv., āā..... gr. i.
Belladonna ext..... gr. ʒ.

M.

S. One t.i.d.

CHRONIC BRONCHITIS.

The administration of the following has been attended with a fair amount of relief in this class of cases:

℞ Oleum lini..... ʒ ij.
Mucilagi acaciæ..... ʒ ijss.
Syr. tolu..... ʒ i.
Ol. terebinth..... ʒ ij.
Aque cinnamomi, ad..... ʒ viij.

M.

S. ʒ ss. t.i.d.

LINIMENT.

The following is quite a favorite for the relief of those cases with which every practitioner is disturbed, and need not be specified:

℞ Tr. aconit. rad..... ʒ ij.
Oleum oliuæ..... ʒ i.
Morphia muriati..... gr. vi.
Chloriformi..... ʒ i.

M.

CATARRHAL AFFECTIONS.

The following is a favorite prescription for catarrhal pneumonia, bronchitis, etc.:

℞ Ammon. muriat.,
Potass. chlorat, āā..... ʒ ij. and ʒ ij.
Aq. aurant. flor..... ʒ ij.
Syr. simplic..... ʒ ij.
Aqua, ad..... ʒ iv.

M.

S. Two teaspoonfuls t.i.d.

NEW DIAPHORETIC.

This is the Aabec bark, and is used in the form of fl. ext. or infusion. Of the fluid extract a teaspoonful is given every hour. It is under trial.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 7, 1875.

LAW vs. PHYSIC.

THE happy fraternization between practitioners of law and medicine which sometimes culminates in the establishment of medico-legal societies, is one of the most satisfactory evidences that there is not an absolute antagonism between the two professions. Were this the case, medical jurisprudence, forensic medicine, or whatever else we may choose to name the branch of scientific and practical inquiry which is the connecting link between the two, would be a perpetually hostile arena, in which the athletes of both corps would find an ever-present opportunity for the display of their intellectual prowess and physical force. Rather let us entertain the belief that these men, educated for high and noble motives, honorable rivals in different fields, may, by the judicious employment of their culture and ability, prove to the world at large that through many elements their sympathies flow in perfect accord, and that the instances of clashing and of professional differences which in the courts of justice are sometimes exhibited to the gaze of an open-mouthed public, are only illustrations of individual weaknesses, and not of an underlying current of natural enmity or unfriendly jealousy. When, however, a medical witness, skilled and true, becomes an involuntary target for the shafts of a high legal functionary, who discards his views as trivial, and almost spits upon his conscientious and unbiased evidence, in the effort, unfortunately successful, to procure a verdict against the prisoner, the questions naturally arise, How much of this is blundering ignorance; how much interprofessional antagonism? How far shall this be tolerated without redress? Especially are we stirred to such inquiries when we find, after the lapse of years, the same case revived, under almost similar circumstances, to be settled, at this second investigation, in a directly opposite manner, and in full accordance with the views originally expressed by the medical expert. Great the triumph

of the latter; marked the discomfiture of his legal adversary! Such cases, with such opposite results, after so brief an interval, seldom or never occur to enable us to point a moral. It will be remembered that about three years ago a young man, a mere stripling of seventeen, physically weak and mentally deficient, was seized at the gates of Buckingham Palace while in the act of pointing an empty pistol at the Queen. The opportunity thus offered for a conspicuous display of loyalty and allegiance to the crown on the part of the Attorney-General, and even of the Judge, could not, of course, be neglected, and the conviction of this youth became a paramount necessity. It mattered little that positive evidence of insanity or confirmed feeble-mindedness was interposed as an obstacle; the merciless law condemned him to the cell and the lash, from which last the Queen's clemency alone released him. It will be remembered that the evidence of Dr. Harrington Tuke was clear and incontrovertible: the prisoner had long been an invalid, had received an injury to his head which seemed to affect his whole nature; hereditary predisposition to insanity existed; he had suddenly resolved upon a threatening assault on the Queen,—an attempt upon the person or the life of one high in place, which is so frequently the madman's characteristic; he had been under Dr. Tuke's care for mental derangement for several weeks previous to this *denouement*, with spasmodic recurrences rendering him unsafe to others, even amounting, after his conviction and removal to a penal colony, to positive mania; he had visions by night and delusions by day, incoherences of conversation and of written expression, etc. As too often happens in cross-examinations, the unscrupulous prosecuting officer weakened some of the links of the medical evidence, and then threw down before the jury what seemed to them a broken chain. The result was an immediate verdict, without further speech or testimony, and the poor imbecile was made a judicial victim; while the unprejudiced world, for the first time perhaps since the days of barbaric practices in the treatment of insanity, learned that the punishment of undoubted lunacy was imprisonment and whipping,—the jury, however, in the very acme of their loyalty, deciding that he was eventually sound. Now, after the lapse of three years, we find this youth again in England, near the scene of his former notoriety, with the positive stamp of insanity so plainly visible, that his admission to a lunatic asylum was at once resolved upon. Had the views of the enlightened witness been properly regarded at the time, there would have been substituted for this long interval of hard and cruel servitude the soothing care and comfort that were his due. Let us hope that those who were most active in his prosecution and persecution may learn a useful lesson for their future guidance. We would fain believe, with Dr. Tuke, who has recently communicated his views on this subject to a medical contemporary, that the prosecutor, and "even

the Judge, must surely now deplore his share in a proceeding which consigned a sick and insane boy to degrading punishment, thus perhaps rendering him a hopeless lunatic; he may also regret that he treated a medical witness with much discourtesy, and ridiculed scientific evidence that has ultimately proved correct; and we indulge also with him the hope that "the case of Arthur O'Connor may either lead the English" (and also, we trust, the American) "bar into more extended study, or induce them to receive with greater attention and respect the evidence of those who make medical and other scientific investigations the pleasure and business of their lives."

THE GOVERNMENT REPORT ON CHOLERA.

THE forthcoming report on cholera, by Ely McClellan, Surgeon U. S. A., promises to be a document of unusual value as a contribution to a very interesting and important subject. It will be recollected that the cholera epidemic in this country during 1873 caused such a widespread alarm that Congress passed a resolution directing the Secretary of War to appoint an Army Surgeon to visit the different infected localities, and to study the disease in all its bearings. Dr. McClellan was selected for this purpose, and has probably furnished one of the most exhaustive general histories of cholera ever published in this country.

The first part of the work is to comprise a clinical history of the epidemic of 1873, with chapters on its etiology and prevention, while the second part contains the general history of the disease, its travels, progress, etc., throughout different parts of the world. To these is an appendix of a list of all the published works on cholera, furnished by the accomplished librarian of the Surgeon-General's office, Dr. John S. Billings, Assistant Surgeon U. S. A. This list, considering the reputation of its compiler for bibliographical research, is as near being complete and exhaustive as the best of facilities could guarantee.

When the work is fairly issued from the press we propose to give a more critical review of its contents in detail, but shall at present only refer to some of the conclusions of Dr. McClellan which may be of interest at the season of the year when cholera is liable to make its appearance. These conclusions are as follows:

"I. That Asiatic cholera is an infectious disease resulting from an organic poison, which, gaining entrance into the alimentary canal, acts primarily upon and destroys the intestinal epithelium.

"II. That the active agents in the distribution of the cholera poison are the dejections of persons suffering from the disease in any of its stages. That in these dejections there exists an organic matter, which, at a certain stage of decomposition, is capable of reproducing the disease in the human organism to which it has gained access.

"III. That cholera-dejecta coming in contact with and drying upon any objects, such as articles of clothing, bedding, and furniture, will retain indefinitely their power of infection. That in this manner a sure

transmissibility of the cholera infection is effected, and that a distinct outbreak of the disease may occur by such means at great distances from the seat of original infection.

"IV. That the specific poison which produces the disease known as cholera originates alone in India, and that by virtue of its transmissibility through the persons of infected individuals, or in the meshes of infected fabrics, the disease is carried into all quarters of the world. That cholera has never yet appeared in the Western hemisphere until after its route of pestilential march has been begun in the Eastern world, and that its epidemic appearance upon the North American continent has invariably been preceded by the arrival of vessels infected with cholera-sick, or laden with emigrants and their property from infected districts.

"V. That the respiratory and digestive organs are the avenues through which individual infection is accomplished; that through the atmosphere of infected localities, cholera is frequently communicated to individuals; that water may become contaminated with the specific poison of cholera from the atmosphere, from surface-washings, from neglected sewers, cess-pools, or privies, and that the use of water so infected will induce an outbreak of the disease.

"VI. That the virulence of a cholera demonstration, the contagion having been introduced into a community, is influenced by the hygienic condition of the population, and not by any geological formation upon which they may reside.

"VII. That one attack of cholera imparts to the individual no immunity from the disease in the future, but that the contrary seems to be established."

Dr. McClellan is an advocate for quarantine, and is a believer in the infectious character of the cholera discharges. In referring to the quarantine regulations of New York, he pays a high compliment to the efficiency of the present health officer, and declares that under his superintendence they have been carried out almost to perfection.

The character and utility of this report will, we hope, be incentives for similar ones upon other subjects, which can only be properly made under the direct patronage of the Government, and with all the necessary facilities at the command of a properly authorized investigator.

PRELIMINARY EDUCATION.

THE proper gradation of medical studies and the requirement of preliminary education are subjects which are forcing themselves upon the attention of our Western brethren, and there is a good promise of something being done in the initiation of these very necessary reforms. The Michigan State Medical Society at its recent annual meeting has passed a resolution bearing upon these points, and has given the University of Michigan an opportunity for answer pro or con. Let other State Societies follow the example, and the different colleges will then have no excuse for longer dodging the question on the ground that it has not been fairly presented to them for discussion.

THE AMERICAN PHARMACEUTICAL ASSOCIATION meets at Boston on Tuesday, September 7th.

Reviews and Notices of Books.

COMPENDIUM OF CHILDREN'S DISEASES: a Handbook for Practitioners and Students. By DR. JOHANN STEINER, Professor of the Diseases of Children in the University of Prague, etc. Translated from the second German edition by LAWSON TAIT, F.R.C.S., etc. New York: D. APPLETON & Co., 1875.

DR. STEINER'S work is largely founded on his experience of upwards of fifteen years in the Francis Joseph Hospital for Children, in Prague. While it cannot rank with the extensive treatise of Barthez and Rilliet, and the great unfinished work of Roger, and although it does not differ very materially from a large number of lesser works on diseases of children, yet it is a book which cannot fail to prove of distinctive value in the hands of the practitioner. With the exception of Vogel's treatise (to which we consider it to be decidedly superior), it is the only recent German work on diseases of children which, so far as we are aware, has been translated into English. The following points have attracted our attention.

The author wisely refrains from the traditional division of tubercular meningitis into stages, and is, therefore, enabled to give a picture of the disease which is much truer to nature than are the descriptions given by most authors. Hypertrophy and sclerosis of the brain are treated of together in one article, because clinically they cannot be separated—a happy infringement upon the plan, often too rigidly adhered to, of making the anatomical features of disease the groundwork of its description. In the author's experience all cases of serous apoplexy have either appeared in children who, on minute examination, showed indications of rickets, or they have proceeded from some such starting-point as "a certain kind of latent ventricular dropsy," and he therefore dissents from the opinion of those who consider that it occurs in children who have been previously in perfect health. The diagnosis of chronic hydrocephalus has not, in his experience, been at all facilitated by the practice of cranial auscultation.

The article on epidemic cerebro-spinal meningitis is very short and quite unsatisfactory. The author states that he has had no personal knowledge of the disease, and that he therefore borrows from the observations of Rinecker, Niemeyer, Liebert, Ziemssen, and Hess, but surely from the writings of these gentlemen a much better account of the disease might easily be compiled. In the treatment of convulsions, Dr. Steiner has found little benefit from the use of bromide of potassium, and he considers digital compression of the carotids as of doubtful propriety. Concerning the connection between chorea and rheumatism, he dissents from Roger's view, that the former is always of rheumatic causation. "The connection," he says, "seems to be in the preference on the part of rheumatism for attacking serous membranes, while in chorea the affected part is the spinal meninges." In the treatment of chorea he has found bromide of potassium less serviceable than several other remedies. Following Henoch, he describes, under the name of "chorea electrica," a motor neurosis, in which violent and fitful contractions affect single muscles or groups of muscles, instantaneous in their duration and rapid in their sequence, resembling those produced by faradization; but he omits to mention that this is not the grave affection described, under the same name, by Dubini and others.

The author considers reflex epilepsy to be uncommon in childhood, and he has never seen a case due to intestinal worms. In the treatment, he thinks atropine inefficient and unsafe, and he has never known bromide of potassium to produce a permanent cure. Croup and diphtheria are considered as distinct diseases, the former being classed among diseases of the larynx, and the latter among zymotic diseases; and yet the author does not seem to differentiate them so strictly as we are accustomed to do in this country, since, in his article on acute laryngeal catarrh (false croup), he mentions the absence of diphtheritic patches in the pharynx as a means of diagnosing this disease from true croup. Under the head of croup he speaks of cases beginning with "croupo-diphtheritic pharyngitis," and recommends for such cases the local application of remedies by inhalation, spray, or gargling, of which lime-water has been the most useful in his experience.

The congenital malformations of the heart and great vessels, including the non-occurrence of the anatomical transformations which normally take place at or soon after birth, are very ably treated of. In his observations on the feeding of infants, Dr. Steiner gives his approval to those abominable nursing-bottles which are furnished with "an elastic tube, about six inches long, between the bottle and the mouth-piece." He adds, indeed, that "great care must be taken to keep all the parts very clean," which is almost an impossibility. With this exception, his remarks on feeding are very judicious. The low organisms described by Hallier and others, as found in the blood of patients suffering from diphtheria and other zymotic diseases, the author regards as the result rather than the cause of the morbid process. He considers lime-water the best local application to the throat to cut short diphtheritic exudation and necrosis, and to prevent absorption of the poisonous matter. Lactic acid seems to him to be less efficient, while active cauterization is of only doubtful service, and not to be very highly recommended. The whole article on diphtheria is excellent. The same may be said of the article on the various diseases of the mouth, including stomatitis ulceroosa, noma, and parasitic aphtha.

In the treatment of the dyspepsia of children, Dr. Steiner has found pepsine of very little use. In the treatment of cholera infantum, strong black coffee, with a few drops of rum in it, is spoken of as often very useful in the stage of collapse. Astringents are seldom of service, and their use is a doubtful practice. In the section devoted to the treatment of intestinal obstructions, large injections (of air or liquid), which have attracted much attention of late years, are barely mentioned. The connection between prolapsus ani and stone in the bladder is not mentioned at all. The author recognizes the difficulty of treating inguinal hernia in children with a truss, and yet he considers it advisable that the attempt should always be made. In regard to the diagnosis of peritonitis, it seems to us that Dr. Steiner, in common with most writers, lays too much stress on "the characteristic pain." A short section on "movable spleen" consists of a statement of the leading points in a case observed by the author in a child two years old.

The "general diseases of nutrition," rickets, scrofula, etc., are very carefully and satisfactorily considered. In particular, the author's remarks on the connection between scrofula and tubercle are very judicious. This connection he considers as still far from satisfactorily made out, particularly as regards the theory of the causation of tuberculosis by resorption from centres of caseification; closing with the statement that he is

"inclined to regard the diathesis of the individual as the predisposing, and the irritative condition of the glands as the proximate or exciting cause of the tubercle." The plan recently proposed of feeding children predisposed to scrofula entirely on animal food, he regards as unsound.

In speaking of the varieties of the scarlatinous rash, Dr. Steiner says: "I believe I have observed one phenomenon of a curious but yet doubtful character, presenting sharply marked insular portions of the skin of a milk-white color, or at least much whiter than the rest of the integument, and which I regarded as due to a temporary paralysis of the arterioles." He has also seen a case of that form of post-scarlatinal dropsy described by Frerichs as unaccompanied by any disease of the kidneys. He has seen two cases of hemiplegia following scarlet fever. In the section on the diagnosis of measles, it is stated, erroneously we think, that syphilitic roseola is entirely free from fever. The article on *rötheln* is by no means so full as the American reader would like to see in a German work. The author is not sure that this disease is contagious. It is satisfactory to find in Dr. Steiner another German who is inclined to consider varicella as an independent disease, since it is another sign that our brethren in that country are reconsidering their old opinion that that affection is a modified form of small-pox.

The article on typhoid fever is very well written. The author expresses his fear that the cold-water treatment may not be altogether devoid of danger in the case of children. In common with several recent observers, Dr. Steiner is inclined to attach only a moderate value to the peculiar deformity of the teeth described by Hutchinson as characteristic of syphilitic children, since he has seen it in those who were quite free from syphilis. In regard to the notion that grave affections are liable to be caused by the cure of eczema of the head and face by local applications, he states that about a thousand cases have been so treated under his observation, without the induction of serious mischief in a single instance. He regards alopecia areata as neither parasitic nor inoculable.

Dr. Steiner's style of writing is in general very smooth, but in the additions to the text of his first edition he has not always been sufficiently careful to re-write sections, but has contented himself with inserting passages; consequently those portions of the work which have been amended contain matter which is more or less reiterative, and which does not always read smoothly with the context. The additions are almost entirely confined to the latter portion of the work.

Mr. Tait's translation is more than ordinarily free from Germanisms, of which, however, we have noticed a few, such as "symptom-complex," "have only one occurrence" (for "occur only once,") "instriking" (for "striking in"), etc. Of mere verbal errors and inelegant expressions, some of which may be chargeable to the printer, the following have attracted our attention: "*intercranial* (for *intracranial*) hyperæmia," occurring on p. 6, being a perpetuation of a mistake by the author; "enteritis choleraformis;" "confused" (for confounded); "another two" (for two others); "the skull is still enclosed" (for unclosed), p. 48; "contractio" (for contracture), *passim*; "concurrences" (for concomitants); "scattered with" or "scattered by" (for strewn with); "also (for therefore) during sexual developments," p. 89; "blenorragia" (for rhinorrhagia), p. 107; "cracking a pint of new milk with a glass of champagne"; "exhibition" (for administration) of a drug; "the respirations are exaggerated" (for accel-

erated), p. 171; "Canton Schweiz" and "Schweiz" (for Switzerland); "chyloplastic" (for cheiloplastic); "developed somewhat considerably," p. 211; "shiny" (for slimy), p. 246; "arms" (for anus), p. 254; "mucous hæmorrhages" (for hæmorrhages from the mucous membranes), p. 331; "soup" (for soap), p. 380; and "parasitical" (for parasitidal) "remedy," p. 398.

In many instances the translator has judiciously condensed the author's text, but in a few cases he seems to us to have carried this process too far—as, for instance, in the article on gastromalacia; and we have noted omissions here and there, of which the most important are, the paragraph on the treatment of retro-pharyngeal abscess, two paragraphs on the diagnosis and prognosis of amyloid degeneration of the liver, the one on the symptoms of parenchymatous nephritis, and two paragraphs of the section on the symptoms of intermittent fever. Of positive errors in translation, some of which pervert the author's meaning materially, we may mention the following: "recognized with safety" (for certainty [*Sicherheit*]), p. 29; "the rupture" (for septum) "is generally perforated," p. 45; "a hydromeningocele" (for hydromyelocele) "is formed," p. 70; "the expression of a probable vaso-motor paralysis" (for vaso-motor spasm), p. 76; "tincture of iron" (for tincture of iodine), p. 132; "aqua cerass. myrrhæ" (for aqua ceras. nigræ), p. 139; "no longer capable of exhaustion" (for expansion), p. 170; "the throat" (for thirst) "unquenchable," p. 239; "not very usual" (for unusual) "in young children," p. 247; "catarrhal vulvitis, leucorrhœa and menstruation" (for masturbation), p. 255; "the exit of the kidney" (for urine) "from the calyces," p. 281; "adhesion of the prepuce to the foreskin," p. 289; "due to the urgency" (for agency) "of the lymphatics," p. 327; "cases have occurred where, in opening these abscesses, the large blood-vessels have been injured, and the hemorrhage has been fatal" (for burrowing of pus downwards and fatal bleeding from perforation of the great blood-vessels of the neck by the abscess breaking internally are rare sequelæ of the suppuration [*Eitersenkung nach ebwärts und bei Durchbruch des Abscesses nach innen Eröffnung grösserer Blutgefässe am Halse mit lethaler Blutung bilden seltenerer Folgen dieser Vereiterung*]), p. 340; "the kidneys always suffer more or less in cases of scarlet fever, the usual condition being that of simple catarrh, but it may be excited into parenchymatous nephritis by external influences" (the text reading, "und zwar *unabhängig* von ausseren Einflüssen"), p. 341; "compare" (for confound) "it with primary diphtheritis," p. 343; "sucklings should be weaned, if it be possible, to avoid it whilst cholera is raging" (for, should not be weaned, if it be possible to avoid it, etc.), p. 374; and "iodine and iron" (for iodine and mercury), p. 379.

Mr. Tait has added an occasional note of his own, and has introduced some very judicious hints on the after-treatment of cases in which tracheotomy has been done for croup. He very properly protests against overloading the air of the room with steam, while allowing due importance to a moderate moistening of the air. He has added an appendix of rules for the management of infants, which are praiseworthy in the main, although we regret to observe that he sanctions that form of nursing bottle which is furnished with a long pipe. He has also supplied a tolerably full index. He has committed an error, we think, in not supplying specific head-lines—the words "Diseases of Children" stand alone at the top of every page.

Typographical errors are rather numerous, and we cannot praise the type employed. We have not noticed a perfect "oo" in the whole volume.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 23, 1875.

DR. E. G. JANEWAY, VICE-PRESIDENT, in the Chair.

MYOMA OF THE UTERUS.

DR. FINNELL presented a specimen of fibro-myoma of the uterus removed from the body of a colored woman, who died of pneumonia.

PERFORATING GASTRIC ULCER WITHOUT SYMPTOMS.

DR. LOOMIS exhibited a specimen of perforating gastric ulcer removed from a merchant, who was forty-six years of age, of spare habit, but capable of a great deal of physical exercise without fatigue. He had no hereditary or acquired predisposition to disease. For the past eight or nine years he had been under the observation of Dr. Loomis at different times for bronchial catarrh and follicular faucitis. During the past four years he became the intimate friend of a very intelligent physician who lived in the house with him. Neither to that gentleman nor to Dr. Loomis had the patient ever complained of any gastric symptoms, nor were his family aware that he ever suffered from any such symptoms. On the morning of May 26, he first felt pain in the upper portion of the abdomen, but it was not sufficiently severe to prevent him from following his ordinary business. He described the pain as colicky in character. At six o'clock in the evening he was seized with another attack, which he located to the left of and on a line with the umbilicus. This pain was so intense that it caused him to cry out, and compelled him to assume a sitting posture.

Within an hour after he first felt this pain, Dr. Loomis saw him. He was then sitting in the chair, bending forward, and to the left, with an anxious expression of countenance, and complaining that the pain was paroxysmal in character, and extended through into his back. On pressure over the point of pain he seemed to be relieved. There was no rigidity of the abdominal walls, nor was there any sign of tympanites. From the fact that he had been exposed to lead poisoning, an attack of lead colic was suspected. It required about forty drops of Magendie's solution to quiet him. His pulse was 70, and his temperature was normal. There was no vomiting, nor had he vomited, as he stated at the time, since a boy.

The next morning his pulse was 80, his temperature normal, and he was still suffering from his pain. There was some rigidity of the abdominal muscles, and pressure over the seat of the pain increased its intensity. He had taken during the night twenty drops of Magendie's solution. From the fact that there was rigidity of the abdominal walls, although very little of any constitutional disturbance, peritonitis was suspected.

A sufficient quantity of morphine was ordered during the day to keep him perfectly free from pain. While the doctor was talking with him, he complained of a little nausea and vomited. The matters vomited were of a green character. He seemed to be relieved by the vomiting.

In the evening his pulse was increased in frequency, being 120, his abdomen became tympanitic, and the area of tenderness had extended. The administration of opium was then commenced in sufficient quantities to keep him under its influence. Dr. Drake remained with him through the night, and kept up the narcotic influence. In the morning he seemed fully as well as the night before, although the tympanites had increased. His respirations were brought down to 18 per minute, his pulse remaining the same. There was considerable nausea whenever the opium was given in diminished quantity.

At 12 o'clock that day his pulse became small and thready, his abdomen still more tympanitic; he vomited in spite of the opium; his extremities became cold and covered with a clammy perspiration. During the afternoon he passed into a state of collapse, and at four o'clock in the morning he died, fifty-eight hours from the time of the commencement of the intense pain.

The autopsy was made six hours after death, the abdominal cavity being only examined. The parietal portion of the peritoneum at the upper portion of the abdomen was thickened and pigmented. There were adhesions between the liver and the abdominal walls; and fresh recent adhesions between the stomach and the viscera lying in contact with it. The peritoneum throughout its whole extent, both parietal and visceral, was intensely congested, and was covered over here and there with flakes of fibrinous exudation. There was a small amount of turbid serum in the most dependent portion of the abdominal cavity. The intestines were distended.

On the anterior portion of the stomach, at the lesser curvature, there was a small ulceration the size of a three-cent piece. This ulcer looked as if it were cut out by a punch. The stomach was drawn out of position downward and to the left, and was adherent in that position. On opening the stomach its mucous membrane was thickened, intensely congested, and of a darkened hue. At a point corresponding to the seat of ulceration was discovered a destruction of tissue, which at the time of removal was two inches in length by an inch in diameter. This destruction of tissue was guarded by elevated edges which were composed of round-cell sarcoma. There was no evidence of recent sloughing at any point. The pyloric orifice of the stomach was distended, as was also the duodenum. The liver and kidneys were normal.

There were two or three points of interest connected with this case. 1. Such extensive disease of the stomach, evidently of such long duration, without symptoms. 2. If the peritonitis was started by perforation, as was probable, the perforation must have been very small, and the peritonitis was at first localized; but when the evidences of general peritonitis manifested themselves the course of the disease was very rapid. The question came up as to the cause and character of this structural disease of the stomach. Dr. Loomis was of the opinion that the ulcer was primarily the result of a suppurative inflammation, and that the induration was a secondary process.

HEMATOMA OF THE PANCREAS—JAUNDICE.

DR. SATTERTHWAITHE presented a specimen of bloody tumor of the pancreas. The patient was thirty-six years of age, and a clerk by occupation. His family history was good, and he had enjoyed perfect health until 1867, when he had an attack of jaundice following, as he stated, an abuse of alcoholies. He was sick with this for about a month. Shortly after he contracted constitutional syphilis. In 1871 he had a

second attack of jaundice, which lasted four or five months, and last December a third attack, from which he did not recover. Since the second attack he had been moderate in the use of liquor. On the 20th of May he was received into St. Luke's Hospital, and in the course of a week or ten days he died. Just before admission, on the 17th of May, he scratched his lip, when a stubborn hemorrhage occurred, necessitating the application of mechanical pressure for its arrest. He had been a frequent sufferer from hemorrhage of the bowels, due doubtless to the same diathesis.

The history on admission was as follows: Patient emaciated and deeply jaundiced, but mental condition good, although drowsy; spleen and liver slightly enlarged; urine loaded with bile pigments; no casts nor albumen; no ecchymotic spots anywhere over the body; no appetite; tongue dried and coated; pupils equal. There was no change in his condition in the hospital, except that he grew gradually weaker until he died.

The autopsy was made twenty hours after death by Dr. Abbe, the house-surgeon. The intestines were in great part healthy in appearance, except that here and there were some ecchymotic spots, while in the upper part of the ileum the gut seemed to be of a livid purple color for a distance of eleven inches. Between the mucous and peritoneal layers of this portion of intestine there was an extravasation of blood, and the wall of the intestine was fully half an inch thick. The boundary of extravasation was pretty well marked. The opening of the common duct into the duodenum was large enough to admit the end of the little finger. The hepatic and cystic ducts were both dilated and filled with a yellowish white fluid. There were no signs of inflammation in the neighborhood. The pancreas was crowded well back against the spinal column and contained in its substance a bloody tumor. The spleen was congested, as were also the kidneys and portal system. The lungs were healthy and the arteries free from atheroma.

DR. JANEWAY remarked that the patient has been under his observation at Bellevue. When he first saw him his diagnosis was obstructive jaundice. There was no bile in the feces, the liver was slightly enlarged, and the hemorrhages which occurred afterwards were supposed to be due to the effect of blood-poisoning. As his disease seemed to be obstinate, it was thought that emetics might be of service, and for this purpose the tenth of a grain of apomorphia was administered hypodermically. The effect was to produce a little bile in the stools for a couple of days afterwards. He believed that the cause of the jaundice as shown after death was primarily due to the disease of the pancreas, which by its dilatation hindered the escape of bile through the common duct, and lastly, the effusion of blood took place in the substance of the organ, and death was the immediate consequence.

DR. SATTERTHWAITE concurred in Dr. Janeway's views that the extravasations of blood into the pancreas and other tissues, as well as the frequent hemorrhages, were the manifestations of a hemorrhagic diathesis. The history of the case did not show that this condition was due to syphilis or alcoholism, and he was inclined to think that it was due to the presence of biliary salts in the blood.

EXTENSIVE PREPUTIAL EXCRESCENCES.

DR. POST presented a specimen of warty excrescences which he had removed by actual cautery from the penis. The mass was as large as a hen's egg, involving nearly the whole of the glans penis, and so

nearly occluding the preputial orifice as scarcely to admit a No. 18 of the French scale.

FUNGOUS DISEASE OF LOWER JAW.

DR. POST also exhibited a specimen of a portion of the lower jaw, which he had also removed by operation from a patient aged fifty-five years. The disease presented itself in the shape of a fungous mass, which projected from the cancellated structure of the bone, taking the place of the alveolar ridge for about an inch.

The operation involved the removal of the central portion of the bone, extending on one side as far back as the anterior molar tooth, and on the other beyond that point. After dividing the bone on each side with the chain-saw, and before separating the genio-hyoglossi muscles, a ligature was passed through the tongue and secured behind the ears. This was subsequently substituted for a second, which was passed through the tongue farther back and passed over a roll of bandage under the chin. The case did very well, and a considerable amount of new bone was thrown out, giving a prominence to the portion of the face from which the diseased mass had been removed. Dr. Satterthwaite, who examined the tumor, found that it was a fungous growth in which there was an extensive development of epithelium, but it did not show satisfactory evidences of epithelioma; the clinical evidences were also wanting.

A CASE OF SIMPLE MITRAL OBSTRUCTION.

DR. JANEWAY presented a heart, for the opportunity of doing which he was indebted to Dr. Warner. Dr. W. had kept the patient under observation from the time of birth until death, which occurred at the age of 21 years. From early childhood the patient had dyspnoea on the slightest exertion. From 6 to 10 years of age, the patient suffered from repeated attacks of chorea. Between the ages of 16 and 20 years, had dyspnoea, brought on by exertion or imprudence in eating, especially the latter. For the last few weeks before his death, he had been in bed almost all the time, his dyspnoea being extreme. He was also excessively cyanotic, but only slightly oedematous.

At the autopsy, the right heart was found greatly distended with blood, as was also the left auricle. The latter had its walls thickened and its cavity enlarged. The right auricle was in the same condition. The mitral orifice was so small as scarcely to admit the little finger, the valve itself having grown into a funnel shape. On being tested, it held water perfectly, showing that there had been no regurgitation; in other words, that it was a case of pure mitral obstruction independent of diseased action.

The left ventricle was of normal size, and its wall of normal thickness.

The lesions presented in this case were those evidently of mitral stenosis. The disease was almost certainly congenital, and this is a condition of interest in connection with the family history—the father and grandfather having died of cardiac disease. Of this same marked tendency of a family to heart disease he had seen several instances. The most interesting was that of two sisters, under his care at the same time, with mitral stenosis, neither of whom had had rheumatism, and in whom the symptoms of heart disease were manifest about the age of puberty, or a little later.

There was a point which he had noticed on several occasions, viz.: that young people with heart disease, especially mitral stenosis, were apt to be more severely affected at fifteen or sixteen years, and he supposed the

rapid growth of the body, and increase of function had much to do with it, and the opening, sufficient for tolerable comfort before, became too small by the increased demands of the system.

He only saw the autopsy in this case, and gave the history as communicated by Dr. Warner. The doctor said that when he examined him he detected no murmur, but that he would be called on occasions when the boy was suffering from dyspnoea. Whether at other times the murmur characteristic of this condition, to which Prof. Austin Flint, Sr., first drew attention, existed, he was unable to state. That was the peculiar blubbery sound slightly preceding the heart's impulse. He well remembered the time when Dr. Flint was the only one who taught this murmur, and the conditions which produced it rightly, others considering it as indicative of regurgitation. This made one of a series of similar cases. He had examined these people during life, heard this peculiar murmur, and on autopsy subsequently found obstruction at the mitral orifice, but no regurgitation. The first of the series was one in which Dr. Flint called the murmur obstructive, others regurgitant. Dr. J. since then had no doubt about the cause and conditions of this murmur. The autopsy showed brown induration of the lungs, marked nutmeg liver, a slightly enlarged and hard spleen, and hard and extremely congested kidneys.

The heart, which was presented, showed:

1st. A marked enlargement of the right side, and this was sufficiently distended with blood so that before opening the pericardium there appeared to be a distension of the sac with serum. After opening the pericardium the right ventricle and auricle came in view distended with blood, and obscured more of the left ventricle than usual; about eight ounces of blood were removed from the heart cavities.

The right auricle was dilated, and its walls somewhat hypertrophied. The right ventricle was dilated to nearly twice the usual size, and its walls were nearly as thick again as usual. The tricuspid valves were a little thicker than usual, the pulmonary normal. The left auricle was much dilated, and its muscular coat was much thickened, so as to be in some parts as thick as the right ventricle usually is. The endocardium was also thicker than usual, and presented two small calcareous plates.

CANCER OF THE STOMACH AND LIVER.

DR. JANEWAY also presented a specimen of the above with the following history: Martin Dixon, aged 40, native of Ireland, laborer; admitted April 24, 1875. No history of cancer in the family. Patient denies venereal, but has been addicted to drink. About five weeks before admission, while feeling quite well, and still at his work, he noticed a swelling in the upper part of his abdomen, which was hard and *painless*. He does not recollect that it grew gradually larger; indeed, he says it has not increased in size since he first observed it. He has had *no vomiting nor pain after eating*; but a sense of *fulness* follows the ingestion of food and drink.

On admission: He complains of the enlargement of his abdomen, has a decidedly cachectic appearance, and says he has observed a gradual falling off of his appetite and failure of strength for a week or two past. Still he keeps about the ward, and has a *passable* appetite. He is slightly jaundiced, and has light-colored, somewhat *clayey* stools, which afford no evidence of the presence of *colloid* masses. He persists in saying that he has not only never vomited blood, but has not vomited *at all* during this present illness.

Inspection: Shows a distended abdomen, with en-

larged and tortuous superficial veins ramifying over it, and a slight icterode line of skin. A large and hard tumor was discovered, evidently continuous with the liver, extending considerably below the free margin of the ribs, and, on the median line, as far as to the umbilicus; also about four inches to left of median line. Hard, nodular irregularities are distinctly felt over that portion of the organ which extends below the ribs; and, about the middle of right lobe, quite a marked depression in the outline of the anterior border is distinguishable.

The hard, round, lower border of the enlarged left lobe can be distinctly grasped between the thumb and fingers. Patient is put on a tonic treatment—iron, cod-liver oil, small doses of quinine, and as nourishing diet as the hospital will afford.

May 15th. Complains of *pain* over the site of the enlarged liver for the first time. Stools still remain lighter in color than normal; appetite fair, and patient about the ward, declaring that he feels "*first rate*."

A small quantity of fluid in the abdomen is to-day made out by diametrical and peripheral percussion.

May 22d. Diarrhoea for the first time, and quite profuse. Acetate of lead and opium ordered. Diarrhoea continued quite obstinate for four or five days, but finally ceased under the use of opium and acetate of lead.

May 27th. Abdominal fluid increased; no more diarrhoea. Patient has suffered from *prolapsus recti* at intervals for several years; bowel returned to-day, and patient kept in bed with a T-bandage.

June 2d. He has remained in bed since the prolapsus was reduced, and is now losing appetite and emaciating quite rapidly. Slight jaundice exists still. Slight oedema of lower extremities exists to-day. Diarrhoea for two days past. Patient very feeble and rapidly sinking. A noticeable feature of his case has been marked absence of vomiting of any kind, either bloody or otherwise, and freedom from pain; also the short period of time in the past over which his available history extends.

June 3d. Patient died to-day of exhaustion, having had no vomiting, and complained of no pain.

AUTOPSY—June 4th.—Exterior: Slight oedema—most marked in legs. Jaundice and anaemia marked. **Brain:** Not examined. **Lungs:** Oedema in dependent portion. **Heart:** Normal. **Abdomen:** Considerable bile-stained serum in peritoneum. **Kidneys:** Bile-stained, but appear normal. **Spleen:** Normal in size; adherent to greater curvature of stomach; old thickening of capsule on convex surface. **Liver:** Weight, with stomach, 18 pounds. Is markedly enlarged and thickened, and is the seat of very numerous new formations, of sizes varying from a pin-head to an inch or two inches in diameter. Color of these is greenish-white; consistency differs—though, in general, they are hard—some of them a little mushy. The surface of the larger ones, reaching the liver-surface, presents umbilicated centre. **Stomach:** Three enlarged glands are situated along the greater curvature, toward the cardiac extremity, on lower border. The stomach contained about two pints of partly coagulated, blackish blood. A new formation is situated in the walls of the stomach, corresponding in site to the position of the enlarged glands, its centre corresponding to the greater curvature. It is circular in shape, has a raised border, measures nearly three inches in diameter, and its centre presents irregular ulcerations in some places. A quarter of an inch from surface, one small vessel, with open mouth, is observed. On section of border, tumor is soft, gives abundant whitish juice, and at this point is noticed to raise, but not involve,

the mucous membrane. *Small Intestines*: Contain some dark-looking blood. A *diverticulum* is observed near the *ileum*. *Large Intestine*: Slate-colored faeces.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from July 25th to July 31st, 1875.

JANEWAY, J. H., Assistant Surgeon.—Granted leave of absence for four months. S. O. 159, A. G. O., July 23, 1875.

BROOKE, JNO., Assistant Surgeon.—Leave of absence extended one month. S. O. 153, A. G. O., July 27, 1875.

ELBREY, F. W., Assistant Surgeon.—Granted leave of absence for 20 days, and upon its expiration assigned to duty at Frankfort, Ky. S. O. 106, Department of the South, July 27, 1875.

PAULDING, H. O., Assistant Surgeon.—Telegraphic instructions from these headquarters of 21st inst., directing him to proceed with all possible dispatch to Fort Randall, D. T., for duty at that post.

MAUS, L. M., Assistant Surgeon.—Assigned to duty at Nashville, Tenn. S. O. 106, c. s., Department of the South.

TAYLOR, B. D., Assistant Surgeon.—Assignment to duty at United States Military Academy revoked. and ordered to report in person to the Commanding General, Department of Dakota, for assignment to duty. S. O. 151, A. G. O., July 24, 1875.

WORTHINGTON, J. CH., Assistant Surgeon.—Assigned to duty at Fort Melleny, Md. S. O. 143, Military Division of the Atlantic, July 24, 1875.

COMEGYS, E. T., Assistant Surgeon.—Assigned to duty at Fort Wadsworth, N. Y. H. S. O. 143, c. s., Military Division of the Atlantic.

HALL, WM. R., Assistant Surgeon.—Assigned to duty at Fort Gratiot, Mich. S. O. 144, Military Division of the Atlantic, July 26, 1875.

TORNEY, G. H., Assistant Surgeon.—Assigned to duty at Fort Wood, N. Y. H. S. O. 143, c. s., Military Division of the Atlantic.

SHANNON, W. C., Assistant Surgeon.—Assigned to duty at Fort Porter, N. J. S. O. 144, c. s., Military Division of the Atlantic.

SPENCER, WM. G., Assistant Surgeon.—Assigned to duty at Fort Lebanon, Ky. S. O. 106, c. s., Department of the South.

ROSSON, R. L., Assistant Surgeon.—Assigned to duty at Fort Monroe, Va. S. O. 144, c. s., Military Division of the Atlantic.

"A RESEAT FORE THE SISTUM."—The following "Reseat" was given by a travelling doctor to an Indiana man, who paid him ten dollars for it and his advice:

Sasaprilc theard of.....	0 5
Wahoon theard of.....	0 5
Wild Cherrey quart of.....	0 5
One pint of Alkhol.	
2 pound of Shugr.	
One pint of wattr.	

Comlit All.

pr dos one swaller 3 times pr dy Before Eating.

Medical Items and News.

CONDITIONS FOR BECOMING PRACTITIONERS IN BRAZIL.—During a visit to Rio de Janeiro, Professor Jacoud, of the Faculty of Medicine of Paris, made inquiry concerning the conditions imposed on foreigners who might desire to practise medicine in Brazil, and received from the Emperor the following document, dated Feb. 4, 1875:—

"The Brazilian Faculties of Medicine are authorized to permit foreign physicians to answer in their own language to questions that may be addressed to them in the examinations to which they must undergo before they can exercise their profession in Brazil."

THE MICHIGAN STATE MEDICAL SOCIETY, at its annual meeting in June, adopted the following: "*Resolved*, That the Regents of the University are hereby requested by the State Medical Society to make, as soon as practicable, a full three years' graded course of study and lectures obligatory upon all students, and that the requirements for admission into this department be made equal to those for admission to the Scientific Department." A resolution was also adopted asking the faculty of the Detroit School to comply with the spirit of the resolution.

Drs. Jenks, Dunster, Shank, Jerome, and Beach were appointed a committee to confer with similar committees from the States of Ohio and Indiana, and the Province of Ontario, with a view to organizing an association, embracing those States and Michigan, which shall meet semi-annually.

DR. McROBIN, Professor of the Practice of Medicine in Aberdeen University, has resigned his chair, which he has held with honor for forty-three years. Dr. R. Beveridge is spoken of as his successor.

THE CHICAGO MEDICAL EXAMINER, heretofore published by N. S. Davis, M.D., and F. Davis, M.D., is to be consolidated with the *Chicago Medical Journal*. After August 1st it will be known as the *Chicago Medical Journal and Examiner*, and will be edited by Drs. J. Adams Allen and Walter Hay.

THE MEDICAL COLLEGE OF OHIO.—Dr. P. S. Conner has been appointed Professor of Anatomy and Clinical Surgery, *vice* Professor Gobrecht, who has been obliged by continued ill-health to resign.

Dr. Landon R. Longworth has been appointed Adjunct Professor of Anatomy.

The college is building an operating amphitheatre in connection with the Good Samaritan Hospital, of a capacity for seating four hundred and fifty students.

COLLEGE OF PHARMACY OF THE CITY OF NEW YORK.—At a stated meeting held June 17th, the following "Delegates to the Convention of Teaching Colleges of Pharmacy," to meet in Boston, September 7th, were elected: Ewen McIntyre, Charles Rice, Professor P. W. Bedford.

A JUDICIOUS CUSTOM.—The *Medical and Surgical Reporter* mentions a very sensible warning attached to the notice of the death of a little child of scarlatina. "In consequence of the nature of the disease the funeral service will be private, and, therefore, hour and place are not given."

A little forethought on the part of physicians might lead to similar action in cases of death from contagious disease, and avoid what is undoubtedly a frequent cause of sickness.

Original Communications.

ON PERIODICAL MELANCHOLIA.*

By WILLIAM B. NEFTEL, M.D.,

NEW YORK.

AMONG the many cases of intense psychical depression which I have been observing of late, one particular group presents certain characteristic phenomena of great theoretical interest and practical importance. This variety of melancholia I designate by the name of "*periodical melancholia*," and give here, as an illustration of it, the following case:

Mr. H., 48 years old. His father was affected with ossification of the coronary arteries, and died during an attack of angina pectoris, at the age of 73. His mother, now 79 years old, is suffering from melancholia, the first attack of which she had in 1837, the second in 1857, and since then remains melancholic, with only occasional intervals of improvement. Of his three brothers, one died suddenly in his 48th year, the other two and a sister are healthy, though all have a slight tendency to depression of mind.

The patient's health was very good until 1845, when during four months he was dangerously ill with dysentery, from which, however, he entirely recovered. Since 1850 he has had a great deal of pruritus ani, with a mucous discharge. In 1850 he entered the banking business, and filled a position of responsibility, demanding his incessant attention, and a great deal of work. Having experienced much anxiety in his affairs, he had in 1851 an attack of melancholia that lasted two months, after recovery from which he had, at different times, slight attacks until 1861, when he had a second, more severe. Since then he is alternately healthy during several, at the utmost, five months, and is then affected with melancholia, the attacks lasting from four to eleven months. They come on gradually, the patient feeling at first somewhat depressed in mind, as often happens with healthy persons in consequence of some unpleasant occurrence or physical indisposition, though in this case the depression is without any cause. It continues to increase during several days, until it becomes complete apathy, a perfect indifference to all surroundings, a want of decision, an entire loss of courage, with a dread of something fearful and inevitable.

The patient is then unable to attend to his business or any other occupation; he cannot even read, for his thoughts remain concentrated on his own distressed condition, and as he says, there are no words to describe the intensity of his suffering, that would at times make him prefer death to such a life. He is open to none but the most gloomy impressions, and every diversion in other moods agreeable—for instance, a comedy or any amusement—would during the attack produce upon him quite a painful effect. Nothing remains for him but to lead a life of seclusion, to avoid society and all kinds of pleasant impressions, which seem then only to aggravate his condition. His appetite is bad, the bowels constipated, the sleep insufficient and disturbed by frightful dreams; he feels quite weak, and loses flesh. At the height of the attack he often experiences a feeling of chilliness and shivering, also a great deal of itching; has boils and eruptions all over the body, which is not the case during the intervals. At last his condition becomes unbear-

able; he passes an entirely sleepless night, and expects the worst results, when suddenly he finds himself refreshed and healthy, to use his expression, "As if some obstruction had been suddenly removed." He is thus restored to his normal condition, in which he remains during a few months, when a new attack is sure to follow.

He has been treated by most eminent physicians and neuropathologists, but his affection has never been influenced by the different methods of treatment. Dr. Edward H. Clarke, the distinguished physician of Boston, kindly sent him to me, and Nov. 5th, 1873, I saw the patient for the first time, two months after an attack.

He is of middle size, very thin, anæmic, and flushing quite readily. The skin dry, atrophic, unelastic; the subcutaneous veins dilated; the hair of the whiskers broken and split at the ends, causing them to appear as if strewn with sand. The mucous membranes (of the mouth, conjunctiva) are pale, and the muscular system but little developed. There is no deformity of the ears or of the skull, which latter, on the contrary, is well developed. His appetite is good, with occasional dyspeptic symptoms; bowels somewhat costive, prolapsus ani, with slight mucous discharge from the rectum. His sleep was always deficient, not more than four or five hours in the twenty-four, sometimes even less. Pulse 70, respiration 18, costo-abdominal; temperature, 37° C.; weight, 124 pounds.

He is very intelligent, and of excellent business capacities, and not at all hypochondric, but, on the contrary, of a good and gay disposition, always fond of joking, and never thinks of his attacks until they have actually come on. His general health is good, and he has no disposition to catch cold, though he is not strong, especially in the arms, and complains of a cold feeling in the right foot, and itching on the inner surface of the thighs. His mode of living is very regular; he is quite temperate, and entirely abstains from sexual intercourse.

As all the different remedies which had been tried have failed to benefit the patient, I resorted at once to the galvanic treatment, and prescribed at the same time a tonic régime, warm baths, and cold douches, exercise in the open air, etc.

He had altogether thirteen galvanic treatments of the head and cervical sympathetic from November 5th to 18th, and, besides, I treated the prolapsus with induced currents. Under this treatment the patient's health greatly improved: he felt strong, and could walk long distances; his appetite and digestion became good, bowels regular, and the prolapsus very much diminished; he slept seven hours every night, which he had never done in previous intervals. The anæmia disappeared, the pulse became fuller, and the veins less dilated; the skin moist; the hair assumed a natural appearance; he had no more itching, and gained flesh, weighing one hundred and twenty-nine pounds. He felt quite well, and returned to his home.

I advised him to come occasionally to New York and continue the galvanic treatment, in order to prevent, if possible, the recurrence of an attack. But owing to the illness of his partner he had to devote all his time to business affairs; and finding that his health continued to improve, and that he could sleep more than seven hours, he thought he would postpone a prolonged treatment until a more convenient moment, and therefore had but four treatments in December and two in February. His health remained excellent during seven months, from September to April, the longest interval he had had since 1861 (the other intervals being from two to five months), when

* A paper read before the N. Y. Medical Library and Journal Association.

a new attack manifested itself, and the patient returned to my care. I used the same methods of treatment as before (galvanization of the head, sympathetic, etc.), but produced no beneficial effect. I then tried the so-called central galvanization and general faradization, also galvanization of the cord, and all the known electro-therapeutic methods, without the least benefit. On the contrary, the patient grew constantly worse; he lost flesh, became anæmic, the sleep unrefreshing and insufficient, the appetite bad. His intellect, however, remained undisturbed; he perfectly well understood that there was not the slightest material cause for his depression; but it seemed to him that there existed somewhere an obstruction which, if removed, would at once completely liberate him from his intense suffering. He, moreover, felt that this obstruction was not even touched by the treatment. He complained chiefly of want of decision and energy, and entire loss of interest in everything; loss of courage and fear of something dreadful; distress in the præcordial region; impossibility of having any but gloomy ideas; concentration of his whole mind upon his distressed condition, with no power of directing his thoughts to other subjects.

Having exhausted all the known electro-therapeutic methods without avail, I advised the patient to go to the country (to the residence of his brother in Virginia), and try a healthful mode of living; exercise in the open air on foot and on horseback, a nourishing diet, etc. He remained there from April 23d to September 15th without any change in his condition, and at my suggestion returned to New York for further treatment. During his absence I had the opportunity of observing similar cases, and had tried a new method which had proved successful, and which I was anxious to try also in his case. It consists chiefly in the production by the polar method of a condition of anelectrotonus in the cervical sympathetic.

Though his present attack lasted five months, it nevertheless differed in several respects advantageously from all the previous ones. In the first place, the interval between the two last attacks was longer than ever, as it was of seven months' duration. He had not lost so much flesh, and weighed one hundred and twenty-five and one-half pounds, while during the former attacks he would run down to one hundred and seventeen pounds. His appetite and strength were less diminished; the boils, eruptions and itching did not at all return this time, nor did the hair assume the peculiar aspect above described; in fact, all the morbid phenomena within the trophic sphere were less marked than before. He had less dyspepsia and insomnia; the bowels remained regular, while formerly they always were costive; the prolapsus has scarcely troubled him, and perhaps even the depression of mind, profound as it was, did not entirely reach the same degree.

After the first galvanic treatment by the new method he slept well, and felt the next day a great deal better than he had done since the beginning of the attack, though perfectly conscious that it was not yet over. I repeated the same treatment the following days, and his condition continued to improve steadily; he felt more interest in everything, he could read, and even enjoy a theatrical representation, which he could never do during former attacks. After six daily treatments, always followed by a prolonged and refreshing night's sleep, his normal condition was entirely restored. I treated him five days longer, and he left New York in excellent health, and still continues to improve. He has already gained flesh (one hundred and twenty-eight pounds), all his functions

are normal, has seven hours of sound sleep, he feels strong, and is in good spirits. He himself ascribes to the galvanic treatment his present delivery from the attack for the following reasons, in which I entirely concur: Never before had he an interval of seven months. All the former attacks, of which there had been so many within twenty-three years, had terminated suddenly after a sleepless night, during their very acme. This time, on the contrary, the attack ended gradually and slowly, in the course of a week, during which he enjoyed sound and prolonged sleep at night. Moreover, the improvement commenced immediately after the first treatment by the new method, without the least change in his mode of living and without the administration of any other remedy.

The chief points of interest in the described case are:

1. The periodicity of the attacks.

Though repeated attacks of melancholia in the same persons are not unusual, yet they are generally very few and very far apart, and if the patient does not entirely recover, he passes into a permanent state of melancholia, or into some other form of insanity. In our case the attacks recurred yearly during a long period of twenty-three years, and without leading to any secondary affections. The periodical melancholia afforded me an invaluable opportunity for the study of a separate attack in its relation to the healthy intervals, thus throwing some light upon the pathogeny of melancholia in general.

2. Loss of flesh invariably accompanied the attacks, and an increase in weight always followed as soon as they were over. There was not a single exception to this rule, which must therefore be in intimate connection with the phenomena of melancholia. The patient's weight at the acme of the attack was 117, during the interval 129 to 132 pounds.

3. The attack always commences with a subacute anæmia. The general anæmia continues during the entire attack, and disappears during the interval. The skin, the mucous membranes are pale, the pulse small and feeble; the veins, on the contrary, dilated and distended with blood. These phenomena are also quite constant and admit of no exception. The anæmia, therefore, together with the loss of flesh (weight), must necessarily constitute an essential element of the melancholic attack, and I consider these facts of the utmost importance as regards the etiology and treatment of melancholia, as will be seen hereafter. As a corollary I may also mention the morbid alteration of nutrition, as manifested by the boils, eruptions and itching of the skin, the splitting of the hair, etc. At the height of the attack all the secretions seem to be diminished, though I had no opportunity of verifying this assumption by a quantitative analysis of urea, etc., secreted during twenty-four hours.*

The conclusions I have arrived at from observing the phenomena of periodical melancholia may be applied also to the other varieties of melancholia, a short sketch of which I give here.

The state of psychological depression, known as melancholia, is one of the elementary forms of mental diseases, and has been described by Pinel, Esquirol, Falret, Baillarger, Moreau, and a great number of other writers. To Guislain † belongs the merit of having elucidated the fact that the great majority of all mental diseases begin with a melancholic stage, while

* After this paper was already sent for publication, the patient had a new attack, which, however, differs favorably from the previous attacks; he is able to read, he sleeps from five to seven hours, his appetite and digestion are good, and there are no morbid phenomena in the sphere of the trophic nerves.

† Guislain. *Leçons orales*. II., p. 162.

Griesinger* treated this psychical affection (psychosis) in close relation to nervous diseases in general, and Krafft-Ebing† pointed out the analogies of melancholia and neuralgia. Indeed, melancholia can be considered as a psychical pain, a neurosis, a psychical neuralgia of the sensory centres in the cortical substance of the brain, analogous to the neuralgias in the sensitive sphere of the cerebro-spinal axis. In neuralgias the irritability of the affected nervous apparatus is so much altered that the slightest external excitations, mechanical, atmospheric, etc., which would not be felt in the healthy condition, cause great pain. Even those slight but continuous excitations which depend upon the processes of circulation and nutrition, and are therefore normal stimuli and quite imperceptible in the healthy condition, become a constant source of intense pain in neuralgia. The same is the case with psychical hyperæsthesia, called melancholia, with the only difference that in neuralgia the affection is in the sensitive sphere, and manifests itself as bodily pain; in melancholia it is in the psychical sphere, and is felt as psychical pain and depression of spirit.

In the first case the pain is produced by external stimuli, mechanical, atmospheric, etc.; in the second, by psychical perceptions, ideas. In both cases a sympathetic affection in the motor sphere is apt to follow. Thus the part affected by neuralgia is instinctively kept immovable; in like manner the melancholic, affected by psychical pain, lacks power of will, energy, and courage. Again, the convulsive movements which sometimes accompany neuralgia have their analogy in the psychomotor impulses for acts of destruction, so often noticed in melancholics. Lastly, both conditions, neuralgia and melancholia, are sometimes combined in the same subject, and both are often caused by a hereditary disposition, the neuropathic constitution.

We have to distinguish two classes of melancholic affections, melancholia without delirium and melancholia associated with insane ideas, delusions; though there are intermediate forms, and the first can pass into the other. Characteristic of melancholia is the impossibility for the psychical organ to produce any but unpleasant sensations; in other words, it responds with painful emotions to every impression, even to such as otherwise would be quite agreeable. As all the impressions from the outer world are felt in a most painful manner, everything appears to the patient changed and gloomy, and becomes an infinite source of psychical pain. "The painful perception of the outer world," says Krafft-Ebing,‡ "manifests itself clinically in a passive manner; at the beginning the patient seeks retirement, avoids all association, and remains secluded; but afterward he becomes aggressive towards persons and things." His relations to the surrounding world have now entirely changed; he finds no pleasure in anything, nor can he be touched by the misfortunes of others, his own distress being much more intense than all beside. Thus he lives in constant solitude and apprehension. In cases of melancholia without delirium the intellect remains intact; but as every psychical act augments the psychical pain, the patient avoids all occupation, becomes inert, undecided, and brooding over his own sadness. He feels weak, his sleep is insufficient and unrefreshing; he has headache, palpitation of the heart, bad appetite, and constipation; he loses flesh and becomes anæmic. All the morbid symptoms generally exacerbate in the morning, and

with female patients especially during menstruation, while toward evening a slight remission sometimes takes place.

If the melancholic condition is not relieved spontaneously or by the efforts of art, or if it has not passed into some form of insanity, the patient usually becomes convinced that there is no remedy for his grief, and, driven to despair, he attempts, and often commits, suicide.

Like in every other nervous affection, so also in melancholia, there are different degrees and varieties of the disease.

Numbers of persons affected with the milder forms of melancholia are continually met with in life. They mostly have a sad and morose countenance, an irritable and changeable disposition, and are generally considered whimsical, and even malicious, until eventually, with the progress of the disease, after a lapse of years, a suicidal attempt in some of these cases will reveal the true nature of their affection. The great majority of those who commit suicide are melancholics. Even the more developed stages of melancholia are not always recognized, and such patients are sometimes considered as *malades imaginaires* or hypochondriacs. One patient of mine, a married lady, living in wealth and luxury, and sincerely attached to her husband and children, suffers for years with melancholia, associated with great distress in the precordial region. Her disease is considered an imaginary one, as no material lesion of any organ can be discovered, and she is generally advised a change of air and travelling, which invariably aggravate her suffering.

Some of these melancholics, especially women, often resort to religious consolations, and are very apt to embrace a new faith, even at the sacrifice of the happiness of their dearest friends. One of these patients consulted me; she had lately become a Roman Catholic, and says that she is now perfectly happy. But it is easy to see that she is only theoretically happy, and that only the name of her affection has been changed from a simple melancholia to a religious melancholia. She fervently devotes herself to her new religious duties, goes to confession every morning before breakfast, spends hours in meditation, and leads an almost ascetic life. She has become much emaciated, and is threatened with insanity.

A variety of melancholia very frequently met with, especially in men, is hypochondriasis. Here the depression comes from the fear of the patient for his own health, which seems to him greatly imperilled. This state of mind is often induced by some morbid peripheral impressions, caused by a slightly deranged abdominal viscus or any other organ, and these impressions the patient mistakes for dangerous symptoms threatening his life. Hypochondriasis may also be of a central origin, called forth by ideas, by reading medical books or by association with other hypochondriacs. In one of my patients, a gentleman of superior intellect and culture, the hypochondriasis is induced by morbid sensations, originating in the sphere of a branch of the sciatic plexus (left nervus cutaneus femoris posterior). Though looking quite healthy, with all the organs in a perfectly normal condition (except some weakness in the sphere of the sexual organs), he was for years a prey to great fear of paralysis, resulting, as he imagined, from some organic affection of the spinal cord, or of the kidneys, or of the heart, etc.

Melancholia is sometimes accompanied by an intense distress in the precordial region, with palpitation and irregular action of the heart, epigastric pulsation, and other symptoms in the sphere of the vaso-motor nerves—pallor and flushes of the face, cold extremities,

* Griesinger. *Pathologie und Therapie der psych. Krankh.* 2 Aufl. p. 213.

† Krafft-Ebing. *Die Melancholie. Eine klinische Studie.*

‡ Loc. cit., p. 5.

contracted pulse, etc. These phenomena must be attributed to the cardiac plexus, and depend very probably on a vaso-motor spasm of the cardiac arteries, as in some cases of angina pectoris. Attacks of precordial distress in a moderate degree happen, in my opinion, in every case of melancholia. In their highest development (melancholia præcordialis) these acute attacks, more than any other variety of melancholia, are apt to drive the patient to despair, to loss of mind, and to acts of destruction against things, persons, or his own life.

The melancholic state in its further development may become associated with insane ideas, delusions, though occasionally it is so from the beginning. We mostly find this variety of melancholia in cases with extreme precordial distress, and the slight forms of melancholic insanity are generally overlooked. One of my patients, a married lady, of a high moral character, mother of several children, who suffers from melancholy, with precordial distress, is convinced that her unhappy condition is caused by her husband, by incompatibility of their natures; and she is further convinced that she would have been happy had she been married to any one else, or not married at all. And yet her husband is a highly respectable and honorable gentleman, of a beautiful external appearance, of an excellent character and kind disposition, very wealthy, and always ready to spare no expense to satisfy every whim of his wife. She constantly leaves the comforts of her luxurious home, and undertakes long journeys to different places, her principal object being separation from her husband. Her false theory is shared even by her intimate friends, though in reality it is a purely insane idea—a symptom of precordial melancholia with which she is affected.

As the delusions originate from, and are constructed upon the most unpleasant sensations of the patient himself, they must necessarily be of a painful nature. Thus, the intense precordial distress, which even in a healthy person is associated with fear, dreadful apprehensions, etc., in the melancholic gives rise to delusions of danger, of persecution, and of death, embracing every imaginable variety of human misery and suffering.

A most frequent source of delusions in melancholics, are hallucinations, which, as may be easily understood, occur sometimes in such nervous and exhausted persons. The patients hear voices announcing their cruel fate; they see bad spirits, or murderers threatening them; morbid gustatory sensations suggest the idea of being poisoned by enemies, etc. Such hallucinations are also the principal cause of the perverted and dangerous acts of melancholics. "Not unfrequently," says Krafft-Ebing,* "is suicide or homicide their direct consequence, and a desperate act of self-defence against imaginary persecutors. Sometimes the decision to remain mute and refuse all nourishment is induced by a hallucination—a voice prohibiting food and speech." Melancholia, with delusions, if not cured, ultimately passes into the passive or active form. In the first variety (melancholia passiva, attonita) the indecision and loss of energy in the patient leads to a complete abolition of all voluntary activity.

Those who have recovered from this affection describe the feelings of terror and suffering they have endured while in a state of obscured consciousness somewhat similar to a dream, and while unable to perform the simplest act, having lost all voluntary power. They therefore remain motionless in bed or in a cor-

ner, and finally scarcely react to external excitations. It seems as if there were an insurmountable resistance to the psychomotor conduction. In the highest degree of passive melancholia, the patients are in a state of catalepsy; the limbs are flexible as if of wax (flexibilitas cerea), and can remain indefinitely in any given, even uncomfortable position, following only the law of gravitation. There is a high degree of muscular and cutaneous anæsthesia and analgesia, and abolition of reflex irritability; but the vegetative and automatic functions, though considerably weakened, still continue. The eyes express anguish and awe. In the state of passive melancholia the patients do not remain longer than a few months. Sometimes they are suddenly relieved from it as if awakened from a profound sleep; or they pass into some secondary form of insanity, or die during the acme of the disease from paralysis of the nervous centres.

In direct opposition to the passive melancholia is the active variety (melancholia activa, agitata). The patient affected by active melancholia instinctively tries, and sometimes succeeds, to relieve his psychological pain and distress by muscular activity, by constant agitation and locomotion. It seems as if the patient, at the height of his suffering, and by enormous efforts, succeeds at last in overcoming the resistance in the psychomotor sphere, at least for a while. During such a paroxysm of agitation, he runs about in despair, trying to destroy everything, his consciousness being partially or totally obscured.

The active melancholia, if not relieved in a short time, leads to death by exhaustion, or else passes into ineradicable dementia.

At the autopsy of melancholics we find no material lesions of the brain and its membranes, which exhibit an anæmic condition.

I now pass to the consideration of the practical part of the subject, the causes and treatment of melancholia. As in all nervous affections, the most important factor in the production of melancholia is a certain disposition, the inherited neuropathic constitution, and in its highest development known as degenerescence, and described by Morel, Moreau and Legrand du Saulle.* It is progressive in succeeding generations, and this fact, perhaps, explains the increasing tendency to and severity of nervous affections at the present time. The degenerescence manifests itself in different ways—by deformity of the skull, of the ears, the teeth, asymmetry of the face, etc., congenital club-foot and various congenital convulsive and neuralgic affections. Very often there are morbid alterations in the structure or functions of the sexual organs, until in the later generations sterility or impotence put an end to the degenerate families. Those suffering from degenerescence are often eccentric, and among them the so-called inventors are largely represented. The most trifling causes are generally sufficient to induce the severest nervous diseases, and one of their characteristic features is the periodicity of their nervous affections. In persons of a neuropathic constitution, melancholic affections are easily developed under favorable conditions, called exciting causes, which weaken the nervous system in general, and impair the nutrition of the brain. Thus constant mental anxiety, depressing emotions, especially if long continued and associated with insufficient sleep, irregularity in the function of digestion, with sexual and other excesses. In a number of cases I could trace the origin of melancholia in females to the debilitating influence of diseases incidental to pregnancy and the

* Loc. cit., p. 37.

* Legrand du Saulle. La folie héréditaire. Paris, 1873.

puerperal state, mostly in those who have suffered from excessive vomiting during pregnancy, and from want of sleep in nursing the child after confinement. To these circumstances I ascribe the fact that melancholia is oftener met with in women than in men.

According to my observations, melancholia is more prevalent in this country than in Europe, and this I ascribe to the early application to business by men, together with want of sleep and irregularities in the digestive and sexual functions.

From the study of the attacks in *periodic melancholia*, I have every reason to believe that the direct cause of melancholia is anemia of the brain, perhaps only of some part of its cortical substance, induced by a vaso-motor spasm. This assumption is corroborated by the fact that the melancholic attack is accompanied by other phenomena in the vaso-motor sphere—the contracted pulse, the pallor and flushing of the face, the cold extremities, and especially the precordial distress, which latter in the form of angina pectoris, Landois and Nothnagel have shown to be sometimes a pure vaso-motor neurosis following a general spasmodic contraction of the arteries. The alteration of nutrition, the loss of flesh, and the other symptoms of melancholia, are the consequences of cerebral and general arterial anæmia, as I have had the opportunity of observing in the case of periodic melancholia. Of course it is not probable that a spasm should last during the whole melancholic attack, but judging by analogy of other spasmodic affections, the spasms may follow each other in more or less rapid succession, while their effect, which is the nutritive alteration of the brain, may continue during the intervals between the spasms. By admitting this theory, which is based on facts, the phenomena of melancholia can be satisfactorily explained, and the treatment becomes more rational and successful.

The treatment must first be directed against the neuropathic constitution in order to prevent the development of melancholia, and then against the disease itself. As regards the first, I arrived at results that differ from the generally adopted opinion. Those who are affected with an inherited neuropathic disposition are, as a rule, advised to avoid intellectual occupations: children are not allowed to study much, and grown persons are desired not to devote their time to science, art, etc. They have only to exercise their muscular system, to travel, to sport, and lead otherwise a quiet, idle, almost stupid life. Admitting the necessity of muscular exercise, I maintain that the intellectual exercise of the brain is still more important, not only for the healthy, but also for the neuropathic individuals. That idiots do not live long is an established fact; but it is perhaps less known that even the physically strongest persons, the athletes, if not intellectually developed, seldom, if ever, reach an advanced age, and that the oldest persons in any country are generally also the most intelligent. From the history of a number of my own patients affected with grave nervous and psychical diseases it is evident, beyond any doubt, that intellectual training or exercise of the brain is of the utmost value for the neuropathic persons. Thus a patient of mine whose father died of softening of the brain, who inherited degenerescence in the highest degree, and who has been affected with the worst kind of epilepsy since his youth, is now living in his seventh decade, having preserved all his intellectual faculties. He is a charming poet, a writer of great merit, a student of mathematics and political economy, and possesses a profound knowledge of the literature of different languages. His epileptic attacks were quite alarming; nevertheless, he followed his studies in

the universities, and continues them now, often passing whole nights in abstruse mental occupations. The older he grew the milder and less frequent became the attacks; his memory is still good, and he still remains talented and brilliant.

Another patient of mine with inherited degenerescence had his first severe attack of depression when eight years old. He became in his manhood a confirmed melancholic, and once made a suicidal attempt by cutting his throat with a razor. In spite of the advice of his friends and physicians, in his later years he took up the study of the physiology and pathology of the brain and of psychology, and though now about sixty years of age he is comparatively healthy and suffers no more of melancholia.

It is extremely important for persons disposed to melancholia to avoid associating, and especially living, with melancholics. I have had patients who would probably have escaped this affection had they not come into frequent contact with melancholics. A robust and previously healthy person became melancholic after having lived several years as maid to a lady thus affected, and strange to say both complain of the same morbid symptoms. A young gentleman, the only son of a melancholic mother, and who has never been separated from her, suffers exactly in the same way, though otherwise not resembling his mother. A young lady, daughter of a patient of mine, living in a boarding-school in another city, is generally of a cheerful disposition, but becomes attacked with melancholia whenever her mother makes a long visit to that city, and it takes some time for the young girl to recover after the departure of the mother.

On the contrary, association with gay and humorous people, and healthy amusements, are very beneficial for persons of a neuropathic constitution. The effect of laughing and of comic impressions has some important physiological and psychological significance, as pointed out by Hecker.*

As regards the treatment of the disease itself it is necessary to bear in mind that the psychical organ in this state is unable to produce any but painful sensations, and therefore all kinds of excitation, all impressions, even pleasant ones, have to be avoided, and the patient must be advised to keep quiet bodily and mentally. A few days' rest in bed is sometimes the most beneficial remedy. Exercise, travelling, admonition, and religious consolations only aggravate the psychical hyperæsthesia. On the contrary, everything that produces relaxation of the vaso-motor spasm, and congestion to the brain, acts beneficially. Thus prolonged tepid baths and above all opiates, though only palliatives, often make life endurable, especially in the variety of melancholia with great precordial distress.

Other remedies which act similarly may also be tried, like inhalations of ether, chloroform, nitrite of amyl, chloral, etc. I have not tried alcohol, which also produces congestion to the brain, on account of its secondary injurious effects upon the system. Being absorbed by the blood, alcohol retards the oxidizing processes and the tissue metamorphosis, which seem already weakened during the melancholic attack.

From my own experience I have every reason to believe that the most efficient remedy to abolish the vaso-motor spasm, to regulate the circulation of blood in the brain, and to improve its nutrition, is the galvanic current, applied according to a certain method, the details of which will be given in a separate paper.

* Hecker, Die Physiologie und Pathologie des Lachens und des Komischen. Berlin, 1873.

A CASE OF GUNSHOT WOUND OF THE BRAIN.

By S. T. SATTERTHWAITE, M.D.,

BELLAIRE, OHIO.

S., aged seventeen years, male, single, colored, day-laborer, temperate habits. Never had any venereal disease or severe illness. Patient went gunning on the 9th December, 1874, using single-barrelled shotgun, one-half inch bore, and loaded with No. 4 shot. While in the act of climbing between the rails of a fence, the gun was discharged, the load taking effect in the head, one-half inch above the right temple, at the junction of the frontal and parietal bones; the charge carrying before it a large quantity of the brain and its membranes, making a deep furrow or groove, that ran along the course of the coronal suture, three inches in length by one and one-fourth inch in width, finally making its exit at the crown within one-half inch of the superior longitudinal sinus. The opening in the cranium by exact measurement was two and one-half inches in length by one-third of an inch in width. Portions of the cerebrum, in a pulpy state, protruded through this opening. The ragged portions of the scalp that surrounded the wound were blackened and charred by the combustion of the powder, showing that the muzzle of the gun must have been in close proximity with the head of the patient.

I found the patient with all the symptoms of concussion of the brain, from which he rallied in six hours from the receipt of the injury. On the morning of the 10th, I found him in the following condition: Entirely recovered from the effect of concussion; no symptoms of compression; perfectly rational, but much inclined to sleep, he having rested well during the night; kidneys acted twice naturally; complete paralysis of left arm and leg, in fact the paralysis extended over the entire left side; patient had good control over the sphincter muscles.

Memory of the accident and of the circumstances connected with it very good; gave a complete history of how it occurred.

Anæsthesia and analgesia both exist. No pain was produced by pinching or even pricking the integument with a pin. It was impossible for him to tell when my hand was in contact with his arm. A mass of cerebral matter the size of a hulled walnut, and consisting principally of gray matter, was removed as it protruded through the opening in a disorganized state. Patient free from pain.

The patient passed on gradually towards recovery without one unfavorable symptom. From time to time small detached pieces of bone were removed. I am quite sure that at least two ozs. ($\frac{3}{4}$ ij.) of the brain were removed altogether during the recent state of the wound. His mental faculties remained intact during the entire time. His intelligence remained equally as good as it was previous to the receipt of the injury.

January 2d. Wound granulating and filling up. A large fungous growth sprang up through the wound, which was removed with the knife, and its re-occurrence prevented by the use of compress bandage. Sufficiently recovered use of left leg to raise it from the bed. Arm still completely paralyzed. Sense of pain slightly recovered. No sense of touch.

March 5th. Wound entirely closed up and healed over. The use of left leg so far recovered that the patient can walk with the assistance of a crutch. Sense of tact in left leg very good. Sense of pain slightly present. Left arm still useless, and sense of tact slightly present in it.

March 23d. Patient doing well. Can walk without crutch. No use of left arm and hand; sense of tact and pain almost normal in leg, but very slightly present in the arm.

April 14th. Patient was taken suddenly with severe sharp pain in the head, near the site of the wound. Tongue coated; bowels constipated; pulse, 108; temperature, 101°. The cicatrice over the wound was raised at least one-fourth of an inch and throbbing violently. He remained in this condition until the 18th of April and then became comatose.

An incision was made with a common-sized bistoury through the scalp, over the site of the old wound. The blade was passed in to its full length before pus was discharged. It then passed off in large quantities, discharging at least a common-sized teacupful. In half an hour from the time the incision was made the patient raised himself in bed and answered questions intelligently. In a few days he was walking about.

On May 19th the patient was again attacked with severe pain over the entire head and a return of inflammatory symptoms. Violent convulsions then set in, which terminated in death, May 21st.

I thought a history of this case would be interesting, and perhaps useful, for the following reasons:

1. The extent of injury received by the brain and its membranes, and yet such complete recovery taking place without any unfavorable symptoms.
2. The complete recovery of the use of the left leg, while the left arm and hand remained powerless.
3. The loss of brain substance out of that portion of the brain considered the seat of intelligence, without any perceptible loss of the mental faculties.
4. The loss of both the sense of pain and tact, as compared with the seat of injury in the brain.

CURE OF CYSTITIS BY DILATATION OF THE NECK OF THE BLADDER.

EXAMINATION OF BLADDER WITH SPECULUM.

By JOSEPH W. HOWE, M.D.,

CLINICAL PROFESSOR OF SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK.

THE following case affords an illustration of the curative effects of dilatation of the neck of the bladder in chronic cystitis, as well as the feasibility of an ocular examination of the pathological changes progressing in the inflamed viscus.

Ann M. K., æt. 35, occupation domestic (?), was admitted to Charity Hospital, December 9th, 1874. For several years she has been accustomed to use alcoholic liquors. One year previous to admission, a small sore appeared at the entrance of the vagina. It lasted several weeks, and was unaccompanied by a bubo. Subsequently the throat became inflamed, and an eruption appeared on the skin. There was pain in the hypogastric region; frequent desire to micturate, both day and night. Micturition was always accompanied by great pain. She was treated at one of the city dispensaries for inflammation of the bladder and syphilis, but with only a slight abatement in the symptoms.

On admission she complained of pain in the perineum and hypogastric region. The calls to evacuate the bladder were so frequent and painful that sleep could not be obtained. The urine was strongly alkaline, and contained mucus, pus-corpuseles, and a small quantity of triple phosphates. The remains of a syph-

ilitic eruption were still perceptible on the integument.

She remained in the hospital from December 9th to February 25th, without any improvement in the condition of her bladder. On that day (February 25th) I saw her for the first time, and as the ordinary means of treatment had failed, I decided to try the effect of dilating the neck of the bladder, in order to give the organ a rest, and if possible examine the inflamed lining membrane. She was placed under ether, and the urethra gradually dilated with Molesworth's dilator until the canal was large enough to admit my little finger. Then the index-finger was introduced, and, lastly, a small glass speculum measuring nearly three quarters of an inch in diameter. Through this the interior of the bladder was readily seen, and the healthy and diseased portions clearly defined. Around the neck and extending backwards about one inch and a half there was well-marked congestion. The membrane was studded with minute red points, which in some places seemed to be raised considerably above the surface, giving rise to an appearance resembling that of granular lids. There was no appearance of mucus. A piece of red litmus paper, introduced on the end of a sponge-holder, and applied to the membrane, showed a strong alkaline reaction. The bladder was then thoroughly washed with warm water, and the litmus paper again applied to the upper portion of the viscus, but the reaction was still alkaline. The cleansing produced little or no change in the appearance of the inflamed membrane. The patient was then placed in bed, and a hypodermic injection of ten minims of Magendie administered. Next day (Monday) quinine in tonic doses was ordered. She then complained of slight soreness about the urethra, the urine dribbled from the bladder until the fifth day after the operation, when the sphincter muscle again resumed control. On Sunday night, March 3d, she made water but twice. The water was retained in the interval without discomfort. From that time on, micturition was performed in a natural manner, without pain or uneasiness, and when I last saw her, two months from the time of the operation, there was no return of the disease. She had perfect control over the sphincter, and, so far as could be ascertained, a rapid and complete cure of the cystitis had resulted from the dilatation.

The absolute and almost immediate relief afforded in this case is sufficient evidence that the dilatation was the best thing to be done under the circumstances. *Rest* is the great desideratum in chronic inflammation of the bladder. With the organ at rest, the pathological changes effected by inflammation are removed without medication. The daily washing of an inflamed bladder with solutions of nitrate of silver, etc., and the internal administration of buchu, *pareira brava*, *uva ursi*, and alkaline medicines rarely effect a complete cure. The disease is merely retarded; the inflammation is apt to continue as long as the contractions of the organ take place with abnormal frequency. Now the dilatation temporarily paralyzes the sphincter of the bladder, gives the organ a rest, allows the urine to dribble away without pain. The patient is freed from the annoyance of jumping out of bed every hour during the night to micturate, and the sleep necessary to recuperate her exhausted system is readily obtained.

The risk of permanent incontinence has been urged against the operation, but this danger is, no doubt, exaggerated. Where there is inflammation in and near the neck, the tissues are probably softer than natural, and the stretching is, therefore, more readily

effected, and that, too, with less injury to the sphincter than would arise were it dilated when in a normal condition. Even granting the danger, is it not better to have incontinence of urine without pain and inflammation and loss of sleep, than incontinence of urine with them, as well as a strong prospect of the final involvement of other organs in the inflammatory process?

Perineal section, with division of some of the fibres at the neck of the bladder, has been repeatedly tried for the relief of chronic cystitis in the male, and with some success. Dilatation of the neck alone would probably answer as well; it would give the bladder the necessary rest as rapidly as the cutting operation, and with less risk.

With regard to the illumination of the interior of the bladder, the process is the same as for the examination of the vagina or other cavities. The examination may be made with or without the ordinary reflecting mirror. Following cutting operations for stone in the bladder, a small speculum could readily be introduced through the wound, light thrown in, and the pathological changes excited by the foreign body carefully studied.

Progress of Medical Science.

UNUSUALLY RAPID ACTION OF THE HEART.—Dr. Robert Farquharson relates the following interesting case:—A soldier, 28 years of age, was under treatment for acute rheumatism. He complained that for some time he had been short-winded on exertion, and on going upstairs. Twelve months before, he experienced a slight attack of palpitation, but no recurrence of this symptom was experienced until the day before, when he was suddenly and violently attacked. His heart beat very heavily all night, and in the morning he felt so ill and unfit for duty, that he at once reported himself sick. On admission to hospital it was noted that he looked pale and anxious; his breathing was much hurried; the pulse was 116, full, bounding and thrilling, and a loud double bruit was heard at the base of the heart, and down the sternum, while the heart impulse was forcible and heaving. Various remedies were used, and finally he was given fifteen minims of the tincture of digitalis, with an equal quantity of tincture of iron, thrice a day; on the next day the pulse had fallen to 80. Matters went on well for some time, when one morning Dr. F.'s attention was drawn to the very alarming symptoms which the patient presented, and which seemed to threaten a rapidly fatal result. The patient was sitting up in bed, breathing with great effort; his countenance was pale and covered with a clammy sweat; on placing the finger on his pulse, the doctor was able, though with difficulty, to count 216 pulsations in the minute. On listening to the heart itself, the cardiac systoles followed one another with great rapidity, and no bruit could be made out, but the first sound was clearly and distinctly audible. Whilst feeling his pulse, the heart suddenly stopped for several beats, then gave three or four forcible and irregular pulsations, and, on resuming its action, was found to have fallen to 104. The patient then expressed himself as feeling much relieved; the countenance lost its ghastly pallor, and he was able to tell the doctor that the palpitation first began at 9 A.M., and that he had suffered in a similar way, but much less severely, several times since admis-

sion. On the next day he had another, but much slighter, attack.

Dr. F. says that the digitalis was prescribed in his case under the old-fashioned idea of reducing the laboring action of an enlarged and hypertrophied heart, and before modern research had shown that its use in such a case was not only unnecessary, but possibly injurious. The first result of its employment, he says, was to reduce the frequency of the pulse, and the second, he fully believes, was paralysis of the terminal cardiac filaments of the vagi, from that exhaustion which usually follows undue stimulation, and hence the remarkably rapid rate to which the sympathetic urged on the muscular contractions.

This is in agreement with the theory that digitalis at first retards the pulse, whilst larger or longer continued doses inevitably bring about a secondary stage of excitement and great rapidity.—*The British Med. Journal*, June 12, 1875.

THE ANTISEPTIC PROPERTIES OF SALICYLIC AND BENZOIC ACIDS.—Prof. E. Salkowski, of Berlin, has been making some experiments on the relative antiseptic properties of salicylic and benzoic acids, adding these substances to albuminous solutions, and observing their condition subsequently as to turbidity or clearness, reaction, odor of putrefaction, and the occurrence of mould and bacteria. He concludes that salicylic acid in concentrated aqueous solutions can retard putrefaction, but cannot prevent it. He denies that it possesses deodorizing properties, as has been claimed, arguing that a deodorant action is to be explained in one of the following ways: either by the destruction of volatile emanations from the fluid, as permanganate of potash, chloride of lime, or sulphurous acid act; or by absorption, as in the case of charcoal, gypsum and the like, or by disguising the odor of decomposition, as does carbolic acid. He states that salicylic acts in no one of these ways, nor does he consider the assumption of Kolbe tenable, that it acts by breaking up into carbolic and carbonic acids. On the other hand, he declares that benzoic acid possesses much stronger antiseptic properties. He conjectures that the mode of preparation of this acid influences its antiseptic qualities, and recommends only that prepared from wine by the best makers. Another advantage is, that it is very much cheaper than salicylic acid. Our author considers both of these acids alike unfitted for internal use as antiseptics or antizymotics, because they are converted in the blood into soda salts. Neutral substances, or such as pass through the system unchanged, are to be preferred for this purpose. Among these, phenol, its substitution products, such as thymol, and the ethers of phenol, are preëminent.—*Berl. Klin. Woch.*, May 31, 1875.

OPERATION FOR VARICOCELE BY THE SUBCUTANEOUS WIRE LOOP.—Mr. Richard Barwell, Surgeon to Charing Cross Hospital, advocates the treatment of varicocele by the method which he describes as follows: First, it is most important that the vas deferens and spermatic artery be separated from the veins. This is best done by the surgeon standing on the patient's left (supposing the disease to be on that side), and taking that half of the scrotum, about an inch above the testicle, between the left finger and thumb, and feeling for the duct by rubbing the two surfaces of the bag gently together while its walls glide from his grip. When he has thus brought the duct and artery from among the venous plexus, and holds them between his thumb and finger-tip, he must let them slip away to the back, so that he will enclose the veins within the circle of his finger and thumb, and exclude from it the artery and the vas deferens. The digit tips and

slightly compressed scrotum will thus separate the one set of vessels from the other. If, in seeking for the duct, the surgeon have allowed a few veins to slip away with it, he can begin again, with the advantage of having no longer the whole mass, but only a few vessels, to deal with. If he be not sure of having successfully isolated this important part, he must examine the condition of things with his right hand while keeping the left in the same position. Supposing this separation accomplished, the bit of scrotum between the finger-tips is to be squeezed rather tight, and a needle, armed with iron or silver wire, not too fine, thrust straight through above them. Now the part may be released from the grasp, and the needle passed in again at the puncture of exit, in front of the veins, and out at the first place of entrance. Thus at one opening protrude the two ends of the wire, and at the other a loop; by drawing on the ends, the loop is pulled into the scrotal cavity, and closely surrounds the varicocele. Each end is passed through a hole in an instrument, which Mr. Barwell has described in a former paper, and drawn tight enough to make the veins below swell, bulge, and partly consolidate. Every other day, or every day, if time be an object, the wire may be tightened until it has cut through all the consolidated veins, and has come away. No suppuration nor apparent inflammation accompanies the process. The patient need not be confined to his bed after the first forty-eight hours.

Mr. Barwell says that one caution must be given. In passing the needle the second time, *i. e.*, in front of the veins, its course must be entirely in the cavity of the scrotum. If, from over-anxiety to include every vein, or, from other cause, some of the lining fascia be strangulated in the loop, the case will be considerably retarded, and some amount of suppuration, accompanied by swelling in the walls of the sac, is likely to ensue. He says that when the operation is well performed, there is but little pain accompanying or following it, and in some cases where pain in the testicle had previously been severe, relief was the immediate result.

Mr. William Rose, in a note to *The Lancet* in regard to Mr. Barwell's article, says that Mr. Wood, of King's College Hospital, for the past nine years has operated for varicocele by a method which Mr. Rose thinks superior to that employed by Mr. Barwell, in that the ends of the wire loop that surround the spermatic veins are passed through an instrument devised by Mr. Wood, so that the loop is steadily tightened by means of the constant action of a spring. In this way Mr. Rose says that the subsequent daily tightening of the wires, according to Mr. Barwell's plan, is avoided, and he further says that the veins are cut through in a much shorter time. He refers to *The Lancet* of July 4, 1868, for an account of the operation, and a woodcut of the instrument.—*The Lancet*, June 12 and 19, 1875.

HEMORRHAGE IN A CASE OF HEMOPHILIA ARRESTED BY PENGHAWAR DIAMBI.—Cantani having used this drug (see RECORD, Jan. 30, 1875, p. 80) with great success in treating a small wound in the occiput in a hemophilous patient when nothing else succeeded, expresses the opinion that it is on Vogel's theory of its action peculiarly suited to this class of cases, considering the hemorrhage in this disease due rather to a watery blood than to a fragility of the vessels. Penghawar, the fibres of which, he believes, abstract the watery elements from the blood and being thus swollen form an artificial thrombus, would exactly meet the conditions. It should therefore be applied dry.—*Aertzl. Corr.-Bl.—Rundschau*, May 25, 1875.

HOSPITAL MANAGEMENT.

At present a great deal of attention is directed towards the subject of hospital management, especially in connection with the recent action of the Board of Managers of the Presbyterian Hospital. A great many views have been expressed by our correspondents in regard to the subject, and the question has been viewed from such a variety of standpoints that it appears to have had a very thorough discussion. The great difficulty has been to define the proper relations which should exist between the managers and the medical staff. It is natural, in the enthusiasm of defending what we may believe to be our professional rights, to overstep the boundaries of discretion, and claim more than is in reality our due. This has undoubtedly been done by some of our correspondents. If we would arrive at a fair estimate of the true merits of the question, we must not coax ourselves to take too radical a position. In the cause of justice we can always afford to be conservative.

The want of a proper agreement between any board of managers and the medical staff has been a chronic difficulty with many excellent hospitals, and has tended more than anything else to interfere with the prosperity of these institutions. When we take a reasonable aspect of the case, it seems strange that such misunderstandings should exist, especially when we consider the different offices which are required of the respective boards.

The managers and the medical staff are both very essential to the welfare and the proper management of any hospital. The duties of each board are such that there should not be any reasonable desire to extend them into the province of the other. The division of the responsibilities of the manager and the attending medical man are very easy and natural. The office of the former functionary makes him responsible for the care of the hospital in all its relations to the community as a public and charitable institution, while the duty of

the latter pertains to the general medical care of the inmates. The proper and prosperous administration of hospital affairs involves an acknowledgment of the importance of both interests, and every effort should be made to blend them into an harmonious action. As one board cannot well do without the other, there should be a respect for each other's rights.

It is conceded that one of the most important requisites for the successful management of any charitable institution is money. The necessity of its possession, involving as it does skilful financiering, naturally places its pecuniary affairs in the hands of business men. Whatever benefits we as a profession may confer upon the institution after it is fairly endowed, we must acknowledge that such opportunities are proportionate to the pecuniary means for so doing which are placed at our disposal. It is fair to assume that, inasmuch as the board of managers represents the interests of the contributors, it should be entrusted with all that refers to the strictly business management of the institution. We believe that the profession do not question this right, and are willing to concede everything which may even indirectly belong to it. A trouble has been, however, that business men are apt to treat of their affairs in a very business-like manner, and are sometimes guilty of an abruptness of decision and rudeness of action which, from a professional point of view, we cannot always understand. We do not usually make enough allowance for such actions, and we are too ready to explain them in any other light than that of good intentions. This is certainly the charitable way of looking at the question, if we desire to come to any understanding of the real merits of the case.

As we have before remarked, the profession, particularly that part of it which has been seeking hospital appointment, has been in no small degree responsible for all this trouble. We have been so eager to obtain the votes for preferment, that we have forced our place-givers to believe that we have no rights which they may not confer upon us. Our eagerness for office has crucified our professional dignity, and has even lowered us into the domain of sycophancy. Can we blame the appointing powers for the contempt in which they may hold our professional influence? Is it to be wondered at that we have to encounter many obstacles before we can convince them of the limit of their interference in hospital affairs?

We believe that one reason why our opinions do not receive a due amount of respect, is the fact that we do not take the ordinary pains to entitle them to that respect. There is too much trimming to expediency to allow of the proper fulfilment of our duties. In almost every hospital there is a regulation which provides that in all matters pertaining to the medical care of the patients, the board of managers shall consult the medical board, the inference being that it will act in accordance with the advice given. But that this is becoming a mere matter of form is

quite evident from the recent troubles in one of our metropolitan hospitals. The managers may consult the medical staff, if they choose to do so, but they very seldom take any such opportunity. Having the power to make their own rules and interpret them in their own way, there is a constant temptation to overstep their true responsibilities. From a proper understanding of their relations to the medical staff they have drifted into an apparent indifference to their claims, and serious difficulty has been the result. The trouble in the Presbyterian Hospital was caused by just such a condition of affairs, and upon its ultimate amicable solution the establishment of a very important precedent in hospital management depends. The board of this hospital have undoubtedly committed a blunder, but how they can rectify it to subserve the best interests of the institution is still an open question.

We do not see how any disagreement between the managerial and medical boards could arise if each attended to its own business, for in proportion as this was done would harmony of action be promoted. The difficulty has been how to decide the limits of the respective prerogatives to the satisfaction of both parties. The proper way, in our opinion, to accomplish this is to have an adequate medical representation in the board of managers, upon whom the responsibility of deciding vexed questions of supposed interference may rest. These medical gentlemen in the board need not be connected with the institution in any other capacity than that of citizen managers, and who should be entirely independent of any other than the interests of the hospital as a whole. This would be the introduction of a conservative element in our various boards which would tend to exercise a very beneficial influence upon all parties concerned, and prevent many unnecessary misunderstandings, and many disgraceful quarrels. If the profession would restore the influence which they have lost with hospital managers in general, they should strive to secure representation upon boards of management. As one of our correspondents has very truly said, the physician has as much right upon the managing board as the clergyman, and may be of as much use. If this be doubted, we should like to see it proved as the result of actual trial.

—♦♦♦—

A REMARKABLE INSTANCE OF SCARLATINAL CONTAGION.—On the 9th of June a dinner-party and reception were given at a fashionable house at South Kensington, in London. No illness of any kind had been in the house previously. Nevertheless, within two or three days afterwards, out of sixteen persons who were present at the dinner, six were attacked with scarlatina, and several of those who were present at the reception only were attacked with the characteristic sore-throat. Two of the servants were attacked. There is a *suspicion* that the cream furnished on the occasion may have been the conveyer of the contagion, but the investigation, which at last accounts was still going on, had not settled upon the source from which the poison came, or the vehicle of contagion.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 23, 1875.

DR. E. G. JANEWAY, VICE-PRESIDENT, in the Chair.

(Concluded from page 544.)

ANEURISM OF ARCH OF AORTA AND INNOMINATA.

DR. JANEWAY presented a specimen of aneurism with the following history: Thomas Cunningham, 47, Ireland, laborer; admitted February 21st, 1871. One sister died of phthisis. Patient is temperate. Had gonorrhœa. Was well until 7 weeks ago, when he was taken with relapsing fever and sent to Charity Hospital; had one relapse. One week ago left Charity Hospital as cured, but two days before leaving noticed a small painful tumor under the right sterno-clavicular articulation. The tumor seemed to decrease at first after leaving Charity, but two days after it began to enlarge rapidly and gave him great pain.

On admission, complains only of pain in right shoulder and right side of neck and face; appetite good, bowels regular, pulse and temperature normal.

Physical examination reveals a tumor the size of a hen's egg under the right sterno-clavicular articulation extending upwards in the line of the carotid artery. Tumor pulsates. No thrill or bruit. Ordered tr. ergot ʒi. t.i.d.

February 26th. Pain increased in severity. The tumor is now double the size it was on admission. Superficial veins on right side of neck are enlarged. Pulse less distinct in right than left radial artery.

February 27th. Tumor occupies supra-sternal region, being most distinct on right side. Pulsation is distensive and distinct. No thrill and no distinct bruit.

Physical examination of lungs gives bronchial breathing behind, distant on expiration. Heart sounds labored, apex beat indistinct and 1 inch to left of normal position.

March 3d. Patient out on pass.

March 4th. Patient has not returned and is discharged.

Second Admission, December 22d, 1872. Patient was to-day again admitted into this hospital, suffering very severely from an access of his symptoms. The tumor has increased very much. Has considerable dyspnœa, and the pain is very great. He remained for three months, and was discharged improved.

Third Admission. On the 26th June, 1873, he was for a third time admitted, on this occasion for a fracture of lower jaw, the result of a fall through a hatchway on the ship where he was working. He lay quite unconscious for a week and got finally better.

The aneurismal tumor had been found to have increased in size since his last admission.

July 3d. The record book of second surgical division states "that a physical examination was made to-day, showing an aneurism of innominate artery. It is ovoid, $2\frac{1}{2} \times 1\frac{1}{2}$ inches, running obliquely downwards from right to left to border of sternum to the junction of first and second portions. It seems to have come up behind the first rib, and pushes out the sternal end of clavicle. The portion of the tumor protruding is hard, and seems to be almost solid, though by placing two fingers over the tumor pulsation of it seems to separate them. Bruit distinctly heard. Heart is hypertrophied.

July 27th. Aneurism does not seem to trouble him now.

March 14th, 1874. He is marked "discharged cured," nine months after admission.

Fourth Admission, December 16th, 1874. Patient has been working as a laborer constantly since his discharge, without any inconvenience from the tumor, until the middle of last month. The tumor has not perceptibly increased in size. He then noticed slight irritation in larynx. This lasted but for a few hours. At the same time the tumor increased in size, slightly, at its prominent point, and, as he says, was softer and more painful than the rest of the tumor. These symptoms are all that the patient noticed when he applied for admission.

On examination, find tumor occupying the inner margin of the left lateral half of the base of the neck, in size measuring $7\frac{1}{2}$ inches in circumference, $2\frac{1}{2}$ inches in length, $1\frac{1}{2}$ inches in diameter, and protruding from the surrounding parts about $1\frac{1}{2}$ inches. Its growth seems to have been outwards, upwards, and towards the median line, and causing absorption of the sternal end of clavicle. It is hard to the feel, except at its most prominent point, which is soft and fluctuating.

The skin covering it is of the color of the integument about it, except this point last mentioned, which is of a dark bluish red. On firmly grasping the tumor you detect an expansive pulsation synchronous with the cardiac impulse. Auscultation not only reveals the transmitted heart sounds, but also a distinct bruit.

Patient has numbness in right arm and buzzing in right ear; these symptoms came on since his fall into ship's hold. Both pupils alike. Temperature of right side $99\frac{1}{4}$, of left side $99\frac{1}{4}$. Right radial pulse feebler. Has slight cough, which he attributes to cold.

March 2d. Discharged improved.

Fifth Admission. Thomas Cunningham, 51, m., Ireland, laborer; admitted May 15, 1875. One week ago the skin over tumor became red and inflamed. Tumor size of orange is found at situation of interclavicular notch. The skin over the tumor is red and tender, and at its most prominent portion a scab is adherent, under whose edges pus can be seen. The skin is very thin, and there is distinct fluctuation immediately under it; the pulsation here is not expansile, but communicated from aneurism below. On the right side of the sternum pulsation can be felt for a distance outward of about 3 inches, and extending vertically from above the clavicle to second rib. There is numbness of right arm. Right radial pulse weaker than left; neuralgic pains in arm, shoulder, and neck, right side.

Auscultation.—Double murmur over base of heart.

May 20th. Last night scab separated, and a considerable amount of bloody serum escaped. Pressure on lower part of tumor evacuates more. Tumor diminished in size and altered in shape, being compressed laterally.

May 22d. The central portion of tumor is sloughing, small ulcer $\frac{1}{2}$ inch in diameter.

May 25th. Last night the protruding mass came away, being a conical mass composed of laminae of fibrine $1\frac{1}{2}$ inches thick and $1\frac{1}{2}$ inches in diameter. There was a very profuse and almost fatal hemorrhage. Lint was quickly stuffed into the cavity, and pressure brought to bear by the orderly, and the hemorrhage stopped.

May 27th. Tumor has been suppurating freely and discharging great quantities of bad pus.

May 28th. Had another hemorrhage, probably lost 12 oz. blood. Patient is very weak.

June 1st. Had a third hemorrhage last evening. Lost

but a small quantity, but it so reduced his strength that he never fully rallied, and died this morning, 6 A.M.

Correspondence.

THE CONTAGIOUSNESS OF PUERPERAL FEVER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Since reading your editorial on the Contagiousness of Puerperal Fever, in a recent number of THE RECORD, I feel as if I was invited to send for publication the enclosed letters, with a few additional and explanatory remarks. The first letter is one written by me to Prof. Barker, last winter, asking more for advice than for information. It will explain itself, and is as follows:—

FRANKFORT, KY., January 19, 1875.

PROF. FORDYCE BARKER:

DEAR SIR:—I hope that I will not trespass too much on your time by requesting your special attention to this rather lengthy letter, and also a full and pointed answer to the questions discussed therein. The subject is one of very great importance, in my judgment, and very nearly concerns the welfare of suffering women. I will premise by saying that I would not have troubled you about this matter if I could have found in any book anything which would have satisfied me perfectly as to some of the points. I will now relate a series of circumstances, exactly as they occurred, and as nearly as possible in their order:

Dr. D—, of this city, attended a lady with facial erysipelas, from the 9th to 22d of December ult. On the 14th of same month he delivered Mrs. P. (white) of a child at full term. On the 17th she had a low form of fever, with slight peritonitis, and died. On Jan. 13th he delivered Mrs. W. (colored). On the 15th she had the same fever, with similar symptoms, and died on the 16th. On the 14th January he examined the womb of Mrs. W. (white); found it retroflexed, partially prolapsed, and intensely congested, with one or two abrasions on the os. He replaced the womb *with a sound*, and touched the abrasions with tincture of iodine. The following day I was called, in his absence, to see the patient, whom I examined digitally only. I found the uterus prolapsed, retroflexed, and enlarged. I introduced a pledget of cotton wool, saturated with iodoform and glycerin, for the purpose of partly sustaining the womb in its normal position, and depleting it to relieve the congestion. I also introduced into the rectum a suppository of opium and belladonna, to relieve the intense pain which she had in the region of the womb. I transferred the case to him, as he came in during my visit. On the 17th (two days after) I was asked to see the patient in consultation with Dr. D., and found her moribund. She complained of *slight tenderness only* over the abdomen; had diarrhoea and obstinate vomiting. The vomited matter resembled coffee grounds. She died of a low asthenic fever, similar in every respect to that of the first two patients; in other words, of a fever answering the description of that which is termed in your work *puerperal fever*. Mrs. W. was *not pregnant*, as her child was only a few months old.

Dr. D. began treating Louisa (colored) for uterine disease on the 10th of January. On the 13th she had

fever, and on the 17th (same day as Mrs. W. (white) she died. He had in the meantime delivered two women, and treated other cases of uterine disease without any unfavorable symptoms up to date (19th). I forgot to mention that Louisa (colored) was also not pregnant. No other cases of this character have occurred in this county in years, but I hear that in an adjoining county several women, under the care of two physicians (partners), have died very suddenly after delivery.

I know that in one of your articles, embraced in your "confession of faith," you deny that the specific poison of the exanthemata can produce in the puerperal woman true puerperal fever. So the fact of Dr. D. attending the case of facial erysipelas might not have caused this peculiar fever in the lying-in women he afterwards attended. But this point I wish you to consider, viz.: Suppose these puerperal women had pure puerperal fever (which I do not doubt, let the cause be what it may), could Dr. D., after attending these persons, impart by manual examination a specific poison which would cause similar symptoms in a non-puerperal woman? In other words, can a non-puerperal woman have what is called puerperal fever? It might possibly be said that the treatment of the non-puerperal women in these cases had produced a peritonitis rapidly fatal, and not necessarily caused by any specific poison. Trousseau, in his article on perihysterical abscess, mentions cases which might seem similar to these. But, to say the least, they are wonderful coincidences. Refer to your work on "Puerperal Disease," page 449, lines 20, 21, 22. You quote in these lines this remark of Schroeder, "The disease is manually transferable, as the secretions of puerperal fever patients transferred to other women may produce puerperal fever." Can the word "non-puerperal" be prefixed to "women" in this sentence with propriety?

The point which concerns me individually, and is of interest to others, is this: Could I now attend a lying-in woman with impunity, without taking the necessary precautions? and what are the necessary precautions? You will remember that I examined *non-puerperal* Mrs. W., per vaginam, on the 15th, the day after Dr. D. had treated her disease (prolapse, retroflexion, etc.) by local applications, and when it might be supposed that he imparted the specific poison. I also saw her, but made no vaginal examination, the day of her death. I was not near any of the other cases.

Suppose I had attended a case of puerperal fever, genuine in every respect; knowing this fact, and the consequent danger, would the following precautions, which I have taken, be sufficient? Taking off every article of clothing, even hat, boots, fur collar, gloves and cravat, bathing in a strong solution of chloride of lime, washing even my hair; then in another tub, with strong carbolic soap, in hot water, paying special attention to my hands and nails; then in simple water. After this, without touching any clothing which I had laid aside, to dress myself in clothes, from *my skin out*, which were partly new, and others which I had not worn for a month. In your appendix "Puerperal Diseases," first paragraph, beginning on page 516, you say: "Every physician in New York took the greatest precaution to prevent the spread of puerperal fever." What was this precaution? Was it to thoroughly disinfect themselves, change their clothing, and continue to attend midwifery cases, and thereby prevent the disease from tracking them? How long a time, after seeing a case of puerperal fever, would be proper for a physician to refuse to attend a lying-in woman, provided he properly disinfected himself? I ask this question in case it is necessary absolutely to wait for a certain length of time under any circumstances.

I have addressed this letter to you, because I regard you as authority on the points mentioned. I hope you will answer me by letter, or if this is too much trouble, will you be kind enough to hand this to the Editor of THE MEDICAL RECORD, and ask him to publish it. If agreeable, you might write whatever you think necessary, and publish it as an addendum to what I have written. I would like to have your opinion or that of some recognized authority on this subject.

Very respectfully.

W. B. RODMAN.

To this letter, Prof. Barker replied as follows:

"January 24th, 1875.

"DEAR DR. RODMAN:—I am constantly in receipt of letters from different parts of this country and from Europe, in regard to subjects referred to in the work 'On Puerperal Diseases,' but I have received no letter comparable in interest with the one I read from you yesterday.

"Your letter, with its most interesting facts, must be published. . . . But I would make this suggestion. I feel morally certain the coming few weeks will furnish for you, in your neighborhood, or within the sphere of a certain epidemic influence, which will be apparent, additional facts of great value. Will it not be wise to delay the publication until we get all the facts attainable? Perhaps some of your confrères will be able to give you other striking cases; . . . then, with your permission, I will append my remarks.

"Can you not get an authentic statement of the facts, which you refer to as having occurred in an adjoining county?

"Now as regards your questions, I should say that you are perfectly justified in attending a lying-in woman after taking such precautions as you specify. But all the personal precautions that you take will not protect your patient from an overwhelming, pernicious, epidemic influence, and you cannot be held responsible for this when you have used every means known to science to avoid the danger of being a medium of communicating disease.

"After using such means as you describe, I do not think that it is your duty to wait a certain length of time, although there are some very curious facts in medical literature that are very staggering on this point. However, all of these facts occurred antecedent to the knowledge of the chemical action and power of the disinfectants which we now use.

"Yours sincerely,

"FORDYCE BARKER."

As Prof. Barker suggested, I waited nearly two months for the occurrence of similar cases in my own neighborhood, but observed nothing like those which I first reported. I also corresponded with the physicians in an adjoining county, but learned that the rumors I heard were exaggerations, and that a case of non-specific puerperal peritonitis had given rise to the reports. Dr. D., as soon as he learned the nature of his fatal cases, immediately used every precaution, that is, he changed his clothing, and used disinfectants. He continued in practice as usual, and had no more trouble.

Shortly after I received Prof. Barker's letters, I read the article published in the January number of the *Am. Journ. Med. Sciences*, written by Dr. Parry, of Philadelphia. I wrote to him giving the same facts which I had communicated to Prof. Barker, and asked him very nearly the same questions. He answered my letter, and stated that he and Prof. Barker differed in

their views in this. Prof. B. believed that puerperal fever was a disease *sui generis*, whilst he believed that the term puerperal fever was unfortunate, as it was made, by different authors and writers, to include a variety of diseases, such as scarlatina, erysipelas, diphtheria, pyæmia, and septicæmia, etc., in the puerperal woman.

I wrote these facts to Prof. Barker as he requested, and stated that if his views were right, I would find it difficult to explain the cases which occurred here in Frankfort, but that if these cases could be considered septicæmic, or erysipelatous, they could be explained. Billroth and D'Espine both regard septicæmia in the puerperal woman as puerperal fever. Prof. Barker never replied to my last letter.* But it however appears that his prediction that other cases would occur within the sphere of a certain epidemic influence was not verified, and that the "factor" of the disease in the cases mentioned is most probably a poison manually transferred from a case of facial erysipelas to a puerperal woman, and from thence to another puerperal woman, and to two *non-puerperal* women—these latter having abrasions on the uterus, *which were not protected by granulations*. This poison, it seemed, clung to the hands of Dr. D., and could not be removed by ordinary washing with soap and water, but as soon as chloride of lime and carbolic-acid soap were used, they seemed to destroy it—at least Dr. D. had no more trouble after their use.

I merely write these *facts*, and have intimated what my views concerning them are. I do not care to go into any detailed argument or citation of authorities to prove my point. It will at once occur to the reader that rarely indeed do *non-puerperal* women become the victims of this peculiar poison manually transferred. I do not recollect a single instance of this kind mentioned by any authority, and it is on this point that I wish to hear from those who are justly regarded as authorities on the subject.

W. B. RODMAN, M.D.

FRANKFORT, KY.

GUNSHOT WOUND OF ABDOMEN AND PASSAGE OF BALL PER RECTUM.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR: In your issue of July 17th I notice an interesting case of penetrating wound of the abdomen by a pistol shot, and the subsequent passage of the ball per rectum, reported by Dr. Wm. O'Meagher. This case called to my mind one that I had under my care during the early part of the late war, the notes of which I have hunted up, and herewith send you a copy of them, thinking that perhaps they may be of interest to your readers.

John W. Beard, a private of Co. F, 21st N. C. Regt. (Confederate), was wounded at the battle of Winchester, May 25, 1862, by a Minie-bullet, while in the act of climbing over a wall. The ball entered 2½ inches to the left of the second lumbar vertebra. At the time there were no particular indications of the locality of the missile. There were no symptoms of shock at the time, nor was there ever any pain to speak of in the abdominal region. For two days after the wound was received the patient passed bloody urine. There was no discharge of fecal matter nor gas from the wound. The bowels remained in a normal condition, there being from one to two healthy

evacuations daily since being wounded. On the 16th day after the battle the ball passed from the body per rectum while in the act of defecation. The ward-master and a number of the patients heard the ball as it fell into the vessel, and they all bear witness to the fact. At the time, and for a few hours after the wound, the patient was paralyzed in the lower extremities. This condition soon passed off, and since that time the patient has had no uncomfortable symptoms.

June 18, 1862. Patient still doing well.

June 25. Still improving. At this time I was ordered to rejoin my command, and I heard no more of this man till some three months afterwards, when, as I was passing through Gordonsville on my way to Richmond as a guest of Stonewall Jackson's troops, this man accosted me in the street; he had rejoined his regiment, and told me he was feeling as well as ever. It is a matter of interesting speculation where this ball was for this period of sixteen days. Could it have lain in contact with the bowel till it ulcerated through, and this without producing any inflammatory symptoms? Even if the ball passed between the reflections of the peritoneum without touching the membrane, it is impossible to account for the fact that ulceration through the intestine occurred without some peritonitis, when we call to mind the fact of the frequency of inflammation of this membrane from contiguity to inflamed tissues. The fact that there were no fecal discharges would seem to prove that the ball did not pass immediately into the bowel. The most reasonable solution of the matter seems to me to be that false membranous matter was thrown out, surrounding the ball, and thus preventing any direct opening from the outside into the bowel. This case differs from Dr. O'Meagher's in the fact that here we had the large conical Minie-ball, and the wound was open for weeks. In Dr. O'Meagher's case the ball being so very small it might have penetrated the intestine at first, and the hole being so very small it seems that it might have been so covered by a fold of mucous membrane as to prevent the escape of any fecal matter until adhesive inflammation should have had time to close the intestinal wound.

I am, sir, respectfully your ob'd't serv't,

JOSIAH F. DAY, M.D.

Late Surgeon and Brevet Lieut.-Col. U. S. Vols.

No. 77 NORTH MAIN ST., FALL RIVER, MASS. June 22, 1875.

MISTAKES IN PRESCRIPTIONS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR: The letter of the "dispensing chemist," Mr. T. H. Sayre, which appeared in a recent issue of THE MEDICAL RECORD, and in which Mr. S. offers his advice to physicians and pharmacists, contains some statements which challenge criticism and refutation. Mr. S., in his first illustration of physicians' mistakes in prescribing, says that a prescription calling for two drachms of subnitrate of bismuth mixed with two grains of sulphate of morphine, which he refused to dispense, was afterwards made up in "another drug store." This statement must make the impression upon the reader that in "other stores" the dispensers of medicines are less cautious, less conscientious than in Mr. S.'s. If it was not Mr. S.'s intention to create this impression, he ought to have, previous to the publishing of this illustration, ascertained if the dispenser of the medicine at "another store" had not consulted the prescriber, or if the latter had not altered the prescription *before* it was dispensed.

* Dr. Barker's absence from the city will explain this seeming neglect of courtesy.—Ed.

That no pharmacist on Sixth Avenue, or in any other part of the city, would compound such a prescription without applying that *generally observed* rule of precaution may be safely warranted.

Second: If one makes a citation from an authority he is expected to quote it as the authority gives it. But Mr. S., who "intuitively" knew that the potassium bichromate prescription was wrong, was deceived by his intuition when he read from the dispensatory $\frac{1}{2}$ of a grain as the dose, while that authority plainly says it was $\frac{1}{4}$.

Third: Mr. S. pays a very flattering compliment to the physicians whose prescriptions come to his drug store when he says that he has nearly *every day* one or more prescriptions to send back for correction, and one might believe that he is a special attraction for careless and ignorant physicians.

This statement of Mr. S. is regarded as a gross exaggeration by all the pharmacists who have experience from a large prescription business, and in whose pharmacies the latter is far predominating over the fancy, soda-water, and nostrum trade. The favorable impression first made by the apparent good intention of Mr. S.'s letter is destroyed by this statement, which gives it the style and character of a boast.

A PHARMACIST.

Aug. 1, 1875.

SANITARY CONDITION OF RURAL RETREATS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Your article on the "Sanitary Condition of Rural Retreats," including *drainage*, &c., reminds me of a question I have for some time desired to ask, viz., How can we carry water from our sinks and water-closets in our country homes in Maine (where the frost is frequently *four feet deep*), and avoid the risk from a backward flow during the winter, from the freezing of the *mouth* of the drain?

Many have wells in their cellars or elsewhere, within a few feet of their kitchen sinks (and it is very desirable to have them so near); they attempt to carry off the water from the sink by a lead pipe leading into an underground drain, below frost, near the house, but gradually coming to the surface some three or four rods from the house.

The drainage is good till cold weather comes. Then the mouth of the drain freezes, and the frost extends upward a rod or two. Solid materials accumulate, the drain becomes choked, and before spring comes, the water of the well is perceptibly changed by the filthy soakings of the drain. A plan, in detail, for the construction of a drain which shall obviate these difficulties, will accomplish much good in country towns and villages, where they seldom have experts for this business.

A SUBSCRIBER.

[The difficulty in question would no doubt be overcome by sinking the mouths of these drains below the frost mark; in other words, causing them to empty into cesspools four or five feet below the surface. To have these drains as far as possible from the wells is a necessity which need not be suggested to our correspondent.—ED.]

DR. BRAND, a physician of St. Catharines, sixty miles above Memphis, Tenn., was lately shot in the back of his head and instantly killed, by an unknown assassin, while sitting in his office.

HOSPITAL APPOINTMENTS.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Whether there is any established system of favoritism in conferring hospital appointments upon professional men, I have no certain means of knowing. "Veritas" claims that there is such a system, and "Justice" presents a practical suggestion calculated to diminish favoritism, and benefit a larger number of medical men. It is undoubtedly true that too few competent practitioners of medicine, in our large cities, have the advantages of hospital connections to which their inclinations, experience, and acquirements entitle them.

If it is an honor and benefit for the favored few, it surely would be of equal honor and profit to all who could become thus officially connected with the large medical institutions. There is an element of radical injustice in the wholesale appropriation of these honorable and responsible staff positions by the comparatively few medical men who hold them, and who likewise materially control new appointments for the benefit of their own college rings, society cliques, or pupils and *protégés*, through a long series of years.

To cling to a hospital connection is to cling to something esteemed valuable, else such offices would go a begging, which surely is not seen to be the case. It must be of value also in the absence of all pecuniary compensation for professional services, as no salaries are paid. It must be of value also in the face of great personal inconvenience, loss of time, and considerable private expense, for these drawbacks are true of all such public official positions. Any prevailing system, therefore, which deprives the rank and file of the profession (we might say the non-professional portion of the medical fraternity) of the benefits of these appointments, some time during their term of active professional labor, is a species of injustice that has no sufficient excuse for its continued existence.

Our leading medical organizations and societies ought certainly to take this matter into grave consideration for the advantage of their own active members. A surge from the trough of the professional sea will lift the matter into prominence, and a reckoning of its position and consequence, as an obstacle to general progress and mutual good, be made with little difficulty.

Take the case of my very intimate friend. He graduated with credit and some class distinction about eighteen years ago, from one of our best New York medical colleges, served a term in our best general hospital, visited Europe for medical observation, returned and entered the medical corps of the U. S. Army, serving with the rank of major during the entire war. After his retirement from the service he went into the country to practise, made a good living and an excellent professional connection. After seven years he found the way open for his return to the city in which he was born and educated. Business in the city prospers, and he has a clientele that highly respects his professional opinions, and which seeks with the peculiar enthusiasm due to a successful medical adviser the aid that he is able to afford. His local connections are influential, his medical course steady towards a ripe and sound experience, his army service signalized by some exceedingly responsible duties, and several situations of a kind requiring superior executive and administrative skill. He has written and published many worthy and scholarly papers, and enjoys good evidence of possessing some special expertness in some of the branches of medical research and practice. Added to all this, he has likewise the nat.

ural and laudable ambition of his brethren of the faculty and of the hospital staff. He desires to prove himself the man he believes himself to be, and only awaits the opportunity. He intends to wait for an invitation, or, say an appointment, subject to his acceptance. I wonder how long he will have to wait!

His case, though typical of the mass of our regularly educated and estimable practitioners, is not exceptional, nor to be regarded as one of the few with merits deserving reward, and likely enough, in course of time to receive due regard and acknowledgment from boards and faculties. Many hundreds, equally deserving, possibly more so, will never, under the present system, receive any public recognition and reward. They have ceased to consider it possible, and have no realization of a public sentiment in their favor that would be of service to them in an agitation of the question with a view to securing their rights.

My friend is as little likely to receive such rewards as any other of the general run of highly respectable, but unfostered medical men. We call for *the surge from the trough of the professional sea*. The surge will never come from the *crest of the waves*, and will not be a *tidal-wave from the trough*; but time and tide somehow effect great and lasting changes that have always, in the long run, benefited the world.

HOPE.

NEW YORK CITY, July 31st, 1875.

THE PRESBYTERIAN HOSPITAL AFFAIR.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—After a careful reading of the note of "Justitia," published in THE RECORD of July 24, apparently in answer of my note of two weeks before. I can only find in it a labored plea for retaliation upon the "only medical man who held a position on the Board of Managers of the Presbyterian Hospital," because the rule which causes the physicians and surgeons of the hospital to be appointed annually is said to have been introduced by him. There is also to be found in it a criticism upon our hospital appointments, a question THE RECORD has many times ably discussed, but which does not fairly enter into the matter now in hand. The rule of annual appointments, or elections, obtains in most of the hospitals of New York. May we not reasonably and charitably suppose, that in placing it among those of the new hospital there was no intention of making a legal basis for the arbitrary removal of medical officers, but merely a desire to copy the rules of the old New York Hospital, which are closely imitated in some other regulations of the Presbyterian? In view of his years of service in the New York Hospital, where a similar existing rule was never carried out in this or in any analogous way, it cannot be supposed that the gentleman in question ever imagined, if he actually introduced the law, that it would ever be made a justification for a failure to re-elect capable men, against whom their colleagues in the Medical Board had made not even the shadow of a complaint. The law of annual elections is undoubtedly a bad one—one that medical men ought not again to consent to; but no attempt has hitherto been made to put it in force in the manner that has awakened the protests of sixty hospital men. I have never heard it questioned that, under the rule, there was a *legal* right to do just what the directors of the hospital have done; but it is not under that aspect of the case that those who are labor-

ing to uphold the dignity and self-respect of hospital appointees and of the profession are arguing.

Precedent, years of custom, all notions of common good faith, had long since made such regulations null and void in all the hospitals of New York, except in actual emergencies, recognized as such by the Medical Board, such as the insanity of a medical officer, when it has been made available. Perhaps the management of Bellevue Hospital forms an exception to this rule; but that hospital has been under political control, and even there an action, for which some claimed that it made a precedent for the course of the Managers of the Presbyterian, was finally rescinded. "Justitia," like one of your former correspondents, attempts to justify this recent wrong done to the profession, by a counter-charge of previous wrongdoing and injustice on the part of medical men to each other, or of a clique to the profession. To this kind of argument the old answer may again be given—No number of wrongs will make a right. We now have an opportunity, by means of this discussion, to improve the relations between medical men and the directors of hospitals; perhaps even of reforming the present system of medical appointments, about which "Justitia" seems to speak with feeling. Let us as a profession, whatever we may have done in the past, now stand by each other, and not lose a golden opportunity, by our "discordant, dissevered, and belligerent" action, for attaining our true status, while we say and do "the things that make for peace" among ourselves.

I trust that the large majority of the profession, whatever inducements may be held out to us to weaken the influence of our class by sowing dissensions among us, or whatever temptation we may have for retaliations for real or fancied injuries, will be found united on all questions affecting our professional honor or self-respect. I may add that, in the opinion of many, of whom your present correspondent is one, such pronounced views as those of "Justitia," as to "a clique who have attempted to govern our hospital appointments," would be rendered more weighty were they given to the public on the writer's name.

With great respect, I am yours,

D. B. ST. JOHN ROOSA.

July 30, 1875.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from August 1st, 1875, to August 7th, 1875.

MIDDLETON, J. V. D., Assistant Surgeon.—Leave of absence extended one month. S. O. 83, Mil. Division of the Missouri, Aug. 2, 1875.

HUNTINGTON, D. L., Assistant Surgeon.—Relieved from duty in Department of California, and to report in person to the Surgeon General. S. O. 158, A. G. O., August 5, 1875.

BROWN, HARVEY E., Assistant Surgeon.—Assigned to duty at Fort Barrancas, Fla. S. O. 141, Department of the Gulf, July 31, 1875.

STYER, CHAS., Assistant Surgeon.—Assigned to duty at Fort Macon, N. C. S. O. 109, Department of the South, August 3, 1875.

CRAMPTON, L. W., Assistant Surgeon.—Assigned to duty with Battalion 13th Infantry, in camp at Mississippi City, Miss. S. O. 142, Department of the Gulf, August 2, 1875.

LORD, C. E., Assistant Surgeon.—Assigned to duty at Fort Buford, D. T. S. O. 145, Department of Dakota, July 31, 1875.

NAVY NEWS.

August 5th.

LENCH, T. W., Medical Inspector.—Reported his return home, having been detached from the Asiatic station, and granted three months' leave of absence.

Medical Items and News.

THE NEW JERSEY STATE DENTAL SOCIETY.—The New Jersey State Dental Society (fifth annual meeting) recently held a three day's session at Long Branch, N. J. The meetings were well attended and were interesting and instructive. The Board of Examiners was in session during the meetings of the Society, and accepted many practising dentists in accordance with the requirements of the act to regulate the practice of dentistry in New Jersey.

Among the numbers present from New York were Dr. J. G. Ambler, of the First District Society of New York; Dr. R. P. Perry, Dr. A. P. Merrill, and Dr. George H. Perine, delegates from "The American Academy of Dental Surgery." The annual address was delivered by the President, Dr. G. C. Brown, of Mount Holly. The following were the subjects of the essays read: "Operations hurriedly Made and their Opposite," by Dr. T. B. Welsh, of Vineland; "Dental Education," by Dr. C. S. Stockton, of Newark; "The Cause and Cure of the Absorption of the Alveolar Process," by Dr. J. R. Goble, of Hoboken; "The Best Mode of Inserting Partial Sets of Teeth," by Dr. J. Hayhurst, of Lambertville; "Amalgam," by Dr. E. F. Hanks, of Jersey City; "Celluloid vs. Rubber," by Dr. Leo Delange, of Bordentown. In addition to the essays read and discussed, Dr. George H. Perine, President of the American Academy of Dental Surgery, by special request illustrated the use of the galvano-caustic battery for certain operations in dental surgery. The advantages set forth are that the operation is instantaneous, painless, without shock or hemorrhage, all of which is of great importance in surgical operations in the mouth. The Doctor made extended remarks, gave experiences to his professional brethren, and strongly recommended the use of the battery to them. (See page 480, vol. 10, No. 28.)

The following officers were elected for the ensuing year: President, C. S. Stockton, of Newark; Vice-President, J. W. Scarborough, of Lambertville; Secretary, Charles A. Meeker, of Newark; Treasurer, Wm. H. Dibble, of Elizabeth. The next annual meeting of the Society will be held at Atlantic City, on the second Tuesday in July, 1876.

A HOSPITAL IN UTICA, N. Y.—The Faxon Hospital—a building costing \$50,000, the free gift of Hon. Theodore S. Faxon—has been formally opened and turned over to the authorities of the city of Utica. Remarks appropriate to the occasion were made by Judge Bacon, Hon. E. H. Roberts, Hon. Horatio Seymour, and others. Mr. Faxon has three other monuments in Utica which will perpetuate his name and add honor and blessing to his memory—the Faxon Old Ladies' Home, on Faxon street; Faxon Hall, at the junction of Varick and Court streets, for the education of the children of factory operatives by day and night; and Faxon Hospital, the splendid new institution just

opened. The first, cost \$25,000; the second, \$15,000; and the hospital gift, \$50,000—an aggregate of \$90,000.

SAINT MARY'S FREE HOSPITAL FOR CHILDREN.—The Managers of this Hospital have issued cards, signed by Bishop Potter, certifying that the possessor has placed "one brick" in the new Hospital in Thirty-fourth street, adjoining their present building (No. 407 West). The sum represented by this certificate is ten cents, and the money given will represent an actual part of the building. This method of raising funds has before been successfully resorted to for similar purposes, and, it is hoped, will add considerably to the building fund in the present instance. Thirty thousand dollars is needed for the purchase of the two lots required, and the building which is on them.

NEW YORK STATE HOMOEOPATHIC ASYLUM FOR THE INSANE.—The following gentlemen were elected to office at the recent meeting of the new Board of Directors of this Institution, located at Middletown:—President, Fletcher Hayden, Jr.; Vice-President, Grinnell Burt; Secretary, M. D. Stevens; Treasurer, James B. Hulse.

THE PRESBYTERIAN HOSPITAL AFFAIR.—The following preamble and resolutions were adopted at the recent meeting of the Medical Board of the North-Western Dispensary, New York.

Whereas, The Board of Managers of the Presbyterian Hospital of this city, at their last annual election, ignored all precedents and dropped from the Visiting Staff four men of reputable standing in the profession, and against whom said Board of Managers declare that they had no charges to make either as to their professional ability or gentlemanly conduct; and

Whereas, Said Board filled the vacancies thus made without consulting (as is customary) the Medical Board or advising with them regarding said appointees; and

Whereas, Said Board of Managers contemptuously treated all communications from the Medical Board and from the profession at large:

Resolved, That the North-Western Medical and Surgical Society most emphatically approve the action of the late Medical Board, and protest against the injustice of said action of said managers.

Resolved, That in our view a valuable precedent will be established, the dignity of our calling vindicated, and the harmonious action of the members of our profession secured, to meet such cases by our absolute refusal to accept positions made vacant in such a manner.

Committee.

C. S. WOOD, M.D.,
Wm. M. McLAURY, M.D.,
F. K. BOSWORTH, M.D.,
E. K. HENSCHEL, M.D.,
Secs. pro. tem.

DR. GEORGE HERRIOT, late of Yonkers, died suddenly on the 8th instant.

TELEGRAPH OPERATORS are the subjects of a palsy similar in nature to that which is known as "writer's cramp."

APOMORPHIA.—Dr. W. F. Duncan writes:—Will you be kind enough to correct two errors observed in the article on Apomorphia, in RECORD of August 7th? 1. Substitute (gr. ii.) two grains for (gr. vii.) seven grains in the formula given in the article; also substitute three (3) years for two (2) years in the last line.

THE SUBSCRIPTION started among the Parisian medical students for the relief of the sufferers by the inundation in northern France, has reached the sum of 4,230 francs.

Original Communications.

SOME OF THE CONDITIONS UNDER WHICH PNEUMONIA PROVES FATAL.

By FRANCIS DELAFIELD, M.D.

[A paper read before the County Medical Society, May 24 1875.]

Most of us, during the past winter, have had our attention called to the subject of pneumonia. To me one feature of the disease has been especially interesting, namely, the conditions under which it proves fatal; and it is to this aspect of the subject that I would ask your attention this evening.

For the purpose of elucidating some of these conditions I have collated the records of 122 cases of acute lobar pneumonia, all occurring in adults, and in all of which I either made or superintended the post-mortem examinations. Most of the subjects were hospital patients.

By looking at Figures 1 and 2 we see that in the three winter months, December, January, and February, and the three spring months, March, April, and May, we find most of the deaths. In Fig. 1 the maximum is reached in May, in Fig. 2 in January.

Is there any relation between the number of deaths and the condition of the weather?

The weather reports I have employed are those furnished by the Central Park Observatory.

In Figures 1 and 2 is also represented the mean temperature for each month of the year. If we compare the curves of temperature and those of mortality—the dotted line represents the curve of temperature—we see that they nearly correspond. There is, however, an exceptionally high mortality in May, in Fig. 1, without a correspondingly low temperature. We may also notice that the lower temperatures which prevailed in 1874-1875 were accompanied with a greater number of deaths than occurred in the corresponding months of 1873-1874.

At what age do the largest number of deaths from pneumonia occur?

In Figures 3, 1873-74, and 4, 1874-75, we find nearly the same relative mortality for the different

FIG. 1. 1873-1874.

Through the kindness of the Board of Health I have also been furnished with some data regarding all the deaths from pneumonia occurring in this city from March 1st, 1873, to March 1st, 1875. From these records of the Board of Health I have selected only those cases which occurred in persons over five years old, and which seemed to be cases of acute lobar pneumonia.

The entire number of deaths from acute lobar pneumonia during this period of two years,—March 1, 1873, to March 1, 1875, was 2,410. Of this number, 1,134 cases occurred from March 1, 1873, to March 1, 1874; and 1,276 cases from March 1, 1874, to March 1, 1875.

During what months do the greatest number of deaths from pneumonia occur in New York?

ages. The smallest number of deaths is between the ages of 5 and 20; then the number increases every ten years until between 40 and 50 the maximum is reached; then the number again decreases until the age of 70 is reached.

What is the duration of the disease in the fatal cases?

In Figures 5 and 6, representing the two years, we find shown in a striking way the preference of the disease for certain days. Beginning with a few deaths on the first day of the disease, the curve of mortality runs rapidly up and reaches its maximum on the seventh day, then falling somewhat on the eighth and ninth days, it ascends on the tenth. From the tenth day there is a rapid decrease in the deaths, until the fourteenth day,

when the curve rises abruptly. In the same way there is a third maximum on the twenty-first day and a fourth on the twenty-eighth day.

I hope to receive from the Board of Health the records of several more years, and thus to be able to increase the statistics just given.

I have also compared the curves of the range of

3. How large a portion of the lungs is found to be hepatized in fatal cases?

II. What lesions in the other viscera do we find as complications in fatal cases of pneumonia?

III. From what causes do these patients die?

1. From their inability to bear a small local inflammation.

FIG. 2. 1874-1875.

temperature, of the barometer and of the degree of humidity for the same two years, but as they seem to have no definite relation to the curves of mortality they are not printed here.

I will now ask your attention to the facts presented by the one hundred and twenty-two cases of pneumonia in which autopsies were made.

In studying the records of these autopsies I have

2. From the development of constitutional symptoms out of proportion to the amount of lung inflamed.

3. From the solidification of so much of the lungs that respiration is seriously interfered with.

4. From the combination of severe constitutional symptoms and extensive inflammation of the lungs.

5. From the existence of complications.

FIG. 3.

FIG. 4.

endeavored to find answers to the following questions:

1. In what condition do we find the inflamed lung?

1. In what stage of the inflammatory process do we find the lung?

2. How soon after the commencement of the disease are the different stages of the inflammation developed?

IV. What lesions do we find in those patients who have suffered from marked nervous symptoms, delirium, convulsions, and coma?

V. What is the condition of those patients who die suddenly?

1. In what condition do we find the inflamed lung?

This question must be subdivided into three others.

1. In what stage of the inflammatory process do we find the lung?

2. How soon are the different stages developed?

3. How large a portion of the lungs is found to be hepatized in fatal cases?

To designate the different stages of the disease I employ the ordinary terms of red and gray hepatization, using the term mixed or mottled hepatization to characterize the condition of red hepatization passing into gray which is so often found. The term "suppurative hepatization" or "purulent infiltration" I do not employ, for I have never seen that condition. It is

2. How soon after the chill which marks the commencement of the disease does the lung become fully hepatized? How long does it remain in the condition of red hepatization? How long in that of mixed hepatization? and how long in that of gray hepatization?

Of the 31 cases of death in the stage of red hepatization, the exact date of the disease could be fixed in only 10 cases. In these death occurred as follows: in 24 hours, 1 case; in 2 days, 1; in 4 days, 1; in 5 days, 2; in 6 days, 1; in 7 days, 1; in 8 days, 2; in 11 days, 1. It will be seen, therefore, that the lung may remain in the condition of red hepatization for

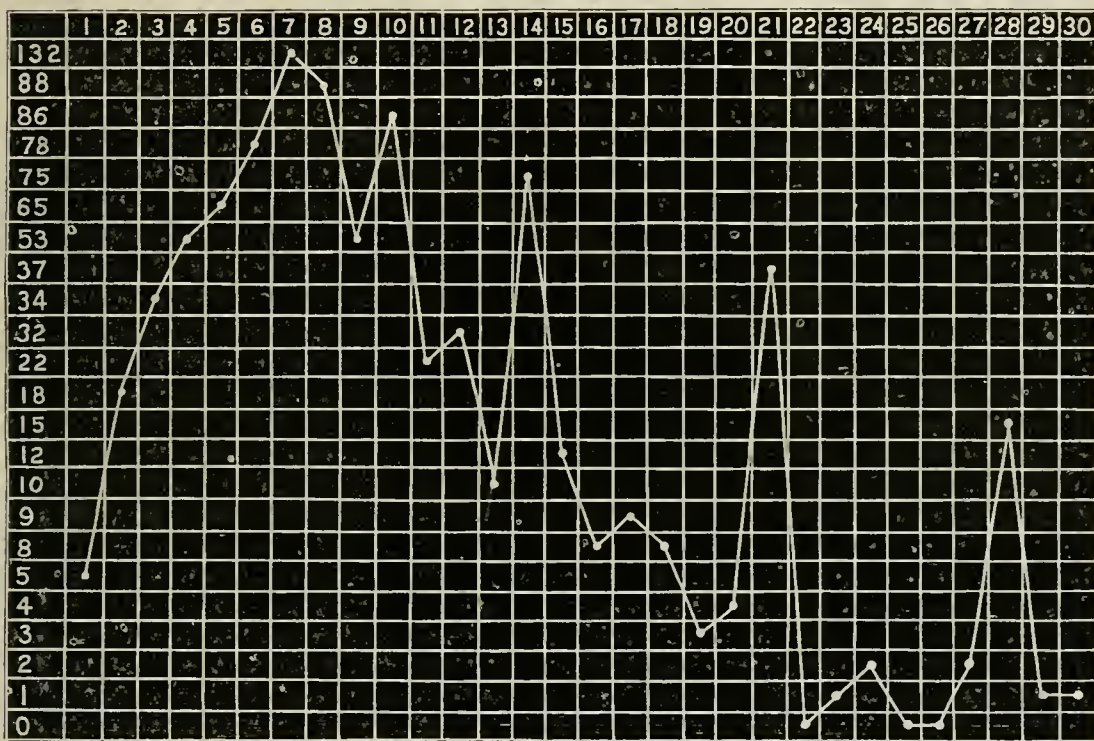

FIG. 5. 1872-1874.

indeed common enough to see lungs in the condition of gray hepatization, which look to the naked eye as if infiltrated with pus, but a minute examination shows precisely the same condition as is found in other hepatized lungs.

1. During what stage of the disease does death occur? In the 122 cases mentioned, I found the lungs to be in the condition of red hepatization alone in 31 cases; in the condition of red and gray mottled hepatization in 59 cases; in the condition of complete gray hepatization in 26 cases; in the condition of hepatization which had passed into gangrene in 2 cases; while in 2 cases the hepatized lung was breaking down in circumscribed spots; and in 1 case the hepatization was becoming cheesy.

Nearly half the cases, therefore, died at the period when the lungs were passing from the condition of red hepatization into that of gray hepatization, while more than one-quarter of the entire number died while yet in the stage of red hepatization.

as long a time as 11 days, and may be completely hepatized in 24 hours.

Of the 59 cases which died during the stage of mixed red and gray hepatization, the duration of the disease could be fixed in 25. In these death occurred as follows: in 2 days, 1; 4 days, 2; 6 days, 1; 7 days, 3; 8 days, 4; in 9 days, 5; in 10 days, 1; in 11 days, 2; in 12 days, 2; in 13 days, 2; in 14 days, 1; in 18 days, 1. The disease may, therefore, be passing from red into gray hepatization by the second day, and it may not have become completely gray by the eighteenth day.

Of the 26 cases which died with the lungs fully in the condition of gray hepatization, the duration of the disease could be fixed in 23. In these death occurred as follows: in 4 days, 1; in 5 days, 1; in 7 days, 3; in 8 days, 1; in 9 days, 1; in 10 days, 4; in 11 days, 1; in 12 days, 3; in 13 days, 1; in 14 days, 2; in 16 days, 1; in 23 days, 1; in 25 days, 1. Complete gray hepatization, therefore, was reached in one

case by the fourth day, in most of the cases not till the seventh day, and in one case lasted 25 days.

Of the two cases in which gangrene of the lung had ensued, the disease had lasted 16 days and 25 days respectively. In one of these cases, the entire right lung was in the condition of gray hepatization, with a large gangrenous portion in its lower lobe. In the other case, the entire right lung was in the condition of mixed red and gray hepatization with a number of gangrenous spots in both the upper and lower lobes.

In the two cases in which there was breaking down of the lung tissues without gangrene, the disease had lasted 8 days and 9 days respectively. These cases merit a more particular notice. Both of the patients were adults, who had been drinking hard for a number of days before they were taken sick. In both of them the constitutional symptoms were marked. They

seemed, therefore, to be one of necrosis of the lung tissue from its infiltration with fibrine, and not one of suppuration.

The case in which the hepatization was becoming cheesy was that of a woman twenty years old who had suffered from severe diarrhoea for five weeks. The duration of the pneumonia could not be fixed. She was much emaciated, delirious, and passed into the typhoid state. The entire right lung was hepatized. The upper lobe was of the appearance seen in the earlier stages of the cheesy hepatization of phthisis, of whitish yellow color, and of firm, dry consistence.

3. How large a portion of the lungs is involved in fatal cases? Of the 122 cases mentioned it was found that in 35 cases portions of both lungs were hepatized and in 25 of these cases not more than one lobe of one lung was left unconsolidified.

FIG. 6. 1874-1875.

became delirious, and died comatose. In one case only the right upper lobe was in the state of red hepatization, and in this were the softened portions. In the other case nearly the whole of both lungs was in the condition of mixed red and gray hepatization, and there were a number of large softened spots in the right upper lobe.

In both cases the condition of the lungs was peculiar. To the naked eye the appearance was that of breaking down of the lung tissue so as to form cavities in which were detached portions of lung. The edges of these cavities looked as if they were infiltrated with pus. This, however, was not the case. A minute examination showed that instead of more pus than usual there was less, and that the principal product of inflammation was fibrine. The process

In 32 cases one entire lung was hepatized, the right lung in 23 cases, the left in 9.

In 54 cases only one lobe was hepatized, in 24 cases the upper lobe alone, in 30 cases the lower lobe alone. Of these in the right lung the upper lobe alone was hepatized in 19 cases, the lower lobe alone in 24. In the left lung the upper lobe alone was hepatized in 5 cases, the lower in 9. Taking all the cases together, both lungs were involved in 35 cases, the right lung alone in 63, and the left alone in 23. It is to be noticed, however, that in some of the cases in which only one lobe of a lung is hepatized that this lobe may be so enlarged that the other lobe is compressed, un-aerated and virtually useless.

II. What lesions do we find in the other viscera as complications? Of the entire 122 cases, in only 15

were there no lesions except the pneumonia. Of these 15 cases in 6 the pneumonia was double, in 6 cases it involved one entire lung, while in 3 cases only one lobe was involved. Of these 3 cases one was a man over eighty, and the other 2 had delirium tremens.

The complicating lesions which were found occurred as follows:

Edema of the remaining part of the lungs in 28 cases.

Emphysema and chronic bronchitis in 21 cases.

Chronic phthisis in 2 cases.

Gangrene of the lung in 2 cases.

A large amount of purulent serum and fibrine in one or both pleural cavities in 16 cases.

Basilar meningitis in 2 cases.

Acute pericarditis in 12 cases.

Valvular disease of the heart in 6 cases.

The liver was fatty in 12 cases.

The liver was cirrhotic in 3 cases.

The liver was waxy in 1 case.

The kidneys were in the condition of chronic Bright's disease in 34 cases.

The kidneys were in the condition of parenchymatous degeneration secondary to the pneumonia in 25 cases.

It will be noticed that these complicating lesions were of so grave a nature, and were present so frequently, that they must have contributed largely to the fatal results of the pneumonia; and that in hospital deaths from uncomplicated pneumonia are comparatively infrequent.

III. From what causes do these patients die?

(1.) From their inability to bear a small local inflammation. The following case affords a very simple example of this cause of death: A man, over 80 years old, after retiring to bed, was attacked at about 11 o'clock with severe pain in the epigastric region; at 7 o'clock the next morning the pain had shifted more to his right side; his breathing was accelerated; his temperature 101° , his pulse 100. There were no physical signs. At 12 o'clock the pain had disappeared, but there were still no physical signs. At 5 o'clock that afternoon there was well-marked crepitation over the right middle lobe in front. The face was becoming anxious, the pulse was feebler and more rapid. He continued in this condition, with rapid breathing, quick and feeble pulse; the feet and hands gradually became colder; the intelligence remained perfectly clear, until, at 11 o'clock, the rapid breathing grew first slower, then interrupted, and then stopped altogether. The autopsy showed red hepatization of the right middle lobe, and of the lower part of the upper lobe. The rest of the lungs and the other viscera were normal. In this case death seemed to take place simply because the vital forces were not sufficient to carry on life when subjected to the depressing influence of a local inflammation. There was plenty of healthy lung left for purposes of respiration; the temperature was not high; there were no secondary lesions or symptoms.

(2.) Death may take place from the constitutional disturbance when only a small portion of the lungs is involved. The following case will serve as an illustration:

A woman, *æt.* 32, had suffered from chronic bronchitis for five months. Twelve days before her death, after exposure to cold and wet, she was seized with several chills, followed by fever. On the second day she had pain in the left side and dyspnoea. On the 5th day she began to vomit, and after that time vomited everything she eat. On the 8th day she was admitted to the hospital; pulse 122, temperature 106° , respiration 42, tongue dry and brown; she had great dyspnoea, oppression, and pain in the side. On the 9th

day pulse 107, temperature $103\frac{1}{2}^{\circ}$, respiration 35. On the 11th day pulse 160, temperature 105° , respiration 48. On the 12th day she died early in the morning. At the autopsy it was found that only the left upper lobe was hepatized, while the rest of the lungs showed the lesions of emphysema and chronic bronchitis.

(3.) So large a portion of the lungs may be hepatized that respiration is mechanically interfered with.

These cases will vary according to the manner in which the lung is invaded. In some cases a large portion of the lungs will be involved at once; in others, only a single lobe will be hepatized at first, and the disease does not extend until after several days; in others there is so much oedema and congestion of the unhepatized portions of lung that they are rendered useless for respiration.

The following case will serve as an illustration of the first method: A man, aged 21, was kicked overboard from a canal-boat into the river. On the second day after this accident he was attacked with chill, dyspnoea, and vomiting. Two days after this he died. His entire right lung was found to be in the condition of mottled red and gray hepatization, while there were numerous lobules of red hepatization in the left lung. This mechanical method of death seems to occur in a large number of cases. Of the 122 cases, in 35 a considerable portion of both lungs was hepatized, while in 28 there was marked congestion and oedema of the rest of the lungs, so that in more than half the cases death seemed to be due to interference with the functions of the lungs.

(4.) Death is caused by the combination of extensive inflammation of the lungs, and of constitutional symptoms. No matter how much of the lungs is inflamed the prognosis always depends much on the constitution of the patient, his capacity of enduring disease, and the degree to which he develops constitutional symptoms. A large number of the deaths is included in this group.

(5.) Death may be due to the existence of complications. These complications, usually in the heart, pleura, and kidneys, seem to destroy life rather by their effect in rendering the patient less able to bear the pneumonia than directly. For this reason they are frequently not discovered until after the patient's death.

IV. What lesions do we find in those patients who have suffered from marked nervous symptoms—delirium and convulsions?

(1.) Patients who died delirious.

In 30 of the 122 cases delirium was a marked symptom. In all of these cases but two, death did not occur till after the seventh day. In most of the cases the delirium did not appear until after they had been sick several days, but in two cases the invasion of the disease was attended with acute mania, which lasted until death. Eight of the patients had been drinking hard for some time before they were attacked with the pneumonia. In 23 of the cases either one entire lung (13), or portions of both lungs (10) were hepatized. Of the remaining seven cases all but one had been drinking hard before they were taken sick. The brain was examined in twenty of these cases. It was found normal in eleven, with acute meningitis in two, with basilar meningitis in one, with increase of serum beneath the pia mater in three, and congestion in three cases. In seven cases there was acute pericarditis; in eight cases there was chronic Bright's disease; in eleven cases the kidneys were in a condition of degeneration secondary to the pneumonia.

So far as these cases go, therefore, the patients who died delirious were those in whom a large portion of

the lungs was involved. The only exceptions were those patients in whom the delirium seemed to be partly due to alcohol poisoning. The large number of these cases in which kidney disease and pericarditis coexisted is also noticeable.

(2.) Patients who died with convulsions.

In five cases the patients died with convulsions succeeded by coma. In four of these cases there was present chronic Bright's disease of long standing. In such cases the convulsions seem to be due to the disturbance caused by the pneumonia in a system already under the influence of kidney disease. In the other case the kidneys were in the condition of parenchymatous degeneration, and there was emphysema of the lungs. In one case the convulsions occurred on the second day of the disease, in the other cases not until near its termination.

In one case the pneumonia was double, in two cases involved an entire lung, and in two cases only one lobe.

The brain was in one case normal, in two cases there was an increase of serum beneath the pia mater, and in two cases it was not examined.

V. What is the condition of those patients who die suddenly?

This method of death occurred in twelve cases. Of these patients five appeared to die from dyspnoea, in three of these death occurred in a sudden exacerbation of the dyspnoea. In these five patients the disease had existed for fourteen, eight, and ten days respectively, in the other two cases the duration was not known. In four of these cases the brain was normal, in the other it was not examined. The lungs were found as follows:

In the first case the entire right lung was hepatized, the left lung was normal; in the second case portions of both lungs were hepatized, and the right pleura was half full of serum and fibrine; in the third case only the right lower lobe was hepatized, and the right pleura was half full of serum; in the fourth case the right lower lobe was hepatized, the right pleura half full of purulent serum, and there was emphysema and bronchitis of both lungs; in the fifth case the entire left lung was hepatized, while the right was normal. The heart was found as follows: In the first case normal; in the second case there was mitral stenosis; in the third case there were large vegetations on the mitral and tricuspid valves; in the fourth case the heart was normal; and in the fifth also normal. In all of the cases the kidneys were diseased. Only two of the five cases, therefore, were uncomplicated, and died in sudden attacks of dyspnoea, with one lung hepatized, the other lung normal, and no heart disease.

In the remaining seven cases of sudden death the patients died as follows:

CASE I.—A man was sick for five weeks with symptoms of bronchitis and emphysema, and with constant vomiting. The exact way in which he died suddenly is not noted. One lung was hepatized; there was general emphysema and bronchitis; the kidneys were far advanced in Bright's disease; the heart and brain were normal.

CASE II.—A man was attacked fourteen days before death with pain in the right side, diarrhoea, cough, dyspnoea, headache. He became delirious towards the close of the disease. He died suddenly without dyspnoea. Just before death his respiration was 38, pulse 104, temp. 102°. The entire right lung was hepatized; the entire left lung was congested and œdematous. The heart was normal, the brain congested, the kidneys diseased.

CASE III.—A man, age unknown, the duration of the disease unknown, had the symptoms and physical signs of pneumonia. He died suddenly, the exact way is not noted. The left lower lobe was hepatized, the right lower lobe was œdematous and congested. There was acute pericarditis; the kidneys were normal; the brain was not examined.

CASE IV.—A man, æt. 25, was attacked sixteen days before his death with chill, fever, pain in his side, cough and rusty sputa, nausea and vomiting. Towards the end of the disease he became delirious. He fell out of bed and died instantly. The left upper lobe was in gray hepatization, the lower lobe congested. Almost the entire right lung was in the condition of commencing red hepatization. The kidney were in the condition of parenchymatous degeneration; the brain was not examined.

CASE V.—A man, æt. 26, had been drinking hard for some time. Four days before his death he was attacked with chill, fever, cough, etc. He was doing very well, and was lying quietly and comfortably in his bed, when he suddenly died. Most of the left lung was hepatized; the right lung was congested; the kidneys were in the condition of chronic Bright's disease; the brain was not examined; the heart was normal.

CASE VI.—A man, æt. 36, of intemperate habits, had been suffering for some time with the symptoms of cardiac disease, œdema, etc. A few days before his death he developed symptoms of pneumonia. He got out of bed to go to the water-closet, and fell dead on the floor. The right lower lobe was hepatized; the heart showed marked valvular disease, with dilatation of the ventricles; the kidneys were atrophied; the brain was not examined.

CASE VII.—A man, æt. 29, of intemperate habits, was attacked seven days before death with chill, fever, etc. Towards the close of his life he developed symptoms of bronchitis; on the day of his death his pulse was 114, respiration 30, temperature 98½°. He died suddenly in his bed, without any warning. The entire left lung was hepatized; the right lung showed emphysema and bronchitis; the brain was not examined; the other viscera were normal.

Of these seven cases in one there was marked organic disease of the heart, but in the other six cases the heart was normal. In these six cases the cause of the sudden death seems fairly to be referable to the lungs, for in four of them there was marked congestion, and œdema of the portion of lung left unhepatized, while in the other two cases there was emphysema and chronic bronchitis. It is not to be overlooked, however, that in four of these cases there was advanced Bright's disease, and in one case acute pericarditis.

In none of these cases of sudden death did the autopsy show that death was attributable to heart clot. Nor have I ever seen in an autopsy on a case of pneumonia any other clot in the heart than the ordinary coagulum which we find in persons dying from all diseases. It is well known that it is the rule to find, after death, in the cavities of the heart, especially the right cavities, coagula which vary in size, color, and consistence. Some are very large, and extend into the large vessels; some are soft, succulent, partly yellow and partly red; some are firmer and whiter; some are entangled in the trabeculae of the heart's walls. These variations seem to follow no definite laws. In sudden deaths from accident or disease, in persons who have died from every variety of acute and chronic disorder, we find in the majority of cases these same clots, larger or smaller, redder or whiter, succulent or dry, but never resembling the real ante-mortem thrombi. Only in persons dying from any of the so-called septicæmic

diseases the blood is often fluid after death, and no coagula are formed.

The assumption of the existence of heart clot in these cases seems to have its only foundation in the symptoms which may exist before death. The patients die suddenly, as if from syncope, from sudden stoppage of the heart's action. Just such sudden deaths apparently from syncope, however, are not infrequent in other cases. Patients who have suffered from chronic phthisis, from chronic Bright's disease, from pleurisy, with effusion of long standing, may all die in this instantaneous way, and in such cases we may find the heart empty, not even a post-mortem thrombus present.

In conclusion, I must remark that I am fully aware that these statistics are entirely insufficient for establishing any certain conclusions, but I trust that they may be of some value as a contribution to the history of pneumonia as it occurs in New York.

PROPHYLACTIC AND ABORTIVE TREATMENT OF EPIDEMIC PUERPERAL FEVER.

By J. H. MILLER, M.D.,

MOBERLY, MO.

DURING the winter of 1873 and '74 puerperal fever prevailed epidemically in this place with extreme virulence and with marked fatality.

I wish to detail briefly the treatment, prophylactic and abortive, which I adopted in my practice during the prevalence of the epidemic, and which resulted in complete success.

After the invasion of the epidemic, the very first case that fell under my care was attacked with puerperal fever on the second day of her confinement.

For thirty years my puerperal cases had run the gauntlet between the sanguinary treatment of Gordon, under the scholarly teachings of the elder Meigs, up to the full opium and veratrum treatment in vogue in more recent times, and of the success or futility of such treatment the profession have had the most conclusive *prima facie* evidence.

I should have been at sea with regard to treatment in this case except for the timely publication in THE MEDICAL RECORD of the clinical lecture of Dr. Fordyce Barker.

Although I did not adopt Dr. Barker's treatment in full, yet his invaluable suggestions saved my patient.

I placed her upon large doses of quinine (small doses being eminently nugatory), with bromide of potassium at short intervals, and as soon as the therapeutic powers of the remedies were established the disease began to yield. The interval between doses was then prolonged, but size of dose maintained. I also gave hypodermic injections of morph. sulph.

On the seventh day from the commencement of her attack she was free from all symptoms of disease, and made a very speedy recovery.

It is not the treatment of established cases, however, to which I wish to call the attention of the profession, but to the prophylactic and abortive treatment of epidemic puerperal fever.

Not unmindful of the trite adage, that "an ounce of prevention is worth a pound of cure," I determined to adopt a course of treatment that might possibly give to my patient some security against the results of this terrible disease. Recalling the antiseptic treatment of Mr. Lister, as a preventive against surgical fever, I concluded to employ it with such additions

and modifications as circumstances might from time to time suggest.

Knowing from long experience that attention to little things frequently makes up the difference between failure and success, I will describe minutely the course pursued in nineteen cases that fell under my observation during the existence of the epidemic.

Upon entering the lying-in chamber and examining its hygienic condition, my first efforts are directed to the proper adjustment of the bed, in order to secure it from liability of being soiled by the discharges—cleanliness being regarded of primary importance. I direct two heavy comforts to be folded upon themselves and placed lengthwise upon the anterior part of the bed, and a sheet folded in the same manner upon the comforts. These will be sufficient to absorb the discharges before reaching the bed proper.

Before making a digital examination I wash my hands with soap and water, cleanse my nails thoroughly, and anoint both hands with carbolated oil, and as soon as the labor is completed I remove everything that is soiled and let her down upon a clean, dry bed. I place a large, folded napkin, carbolated, under the nates, to receive the lochia, and then proceed to anoint her abdomen and thighs with carbolated oil, and place a single cloth saturated with carbolated oil over the entire genital organs. I then order her a glass of whiskey-toddy. The carbolated oil was applied as above thrice daily for three days, and twice per day for two days more. It is both antiseptic and antipyretic. A generous diet was allowed throughout.

For the purpose of securing speedy uterine mural condensation, I order *fld. ext. ergot* in 3 ss. doses thrice daily for the first three days, and twice daily for two days longer. I regard it of the utmost importance to have an early contraction and condensation of the uterine walls, in order to close the mouths of the uterine veins, for the liability to puerperal fever is to a great extent owing to the open, patulous condition of the mouths of the uterine vessels, allowing thereby easy ingress to the mycelium of the spores of microscopic fungi or to the shoals of the swarming bacteria, and thus invading and poisoning the whole uterine, peri-uterine, and peritoneal tissues. Secure by all means an early condensation of the uterine walls, and you thereby lessen the liability to puerperal fever in a ratio with the contraction of the calibre of the uterine veins; and with occasional washing the vagina with tepid water slightly carbolated, that condition of the puerperal state which is so inviting to the invading causes is so materially changed and protected as to render her security almost certain, and reduce the danger to zero.

Unremitting vigilance on the part of the physician is frequently the price of the patient's life. One visit every twenty-four hours is not safe practice. Three visits per day for the first three days, and two visits daily for two days more should be made in every case of labor during the epidemic.

The careful employment of the thermometer at each visit, in order to detect the brewing of the coming storm in advance of the more prodromic symptoms, lest they herald to the tardy physician the sad intelligence that he has come too late, is of the highest importance.

Perhaps without the use of these precautionary means those nineteen cases might have passed unscathed through all the fierceness of the epidemic, and, on the other hand, had it been practised more generally, the fatality of the epidemic might have been much more limited. It is only by more extended observation in this direction that we can arrive at just con-

clusions; for it is only by prophylactic and abortive means that we can expect to do our patients full justice, because in fully established cases the pathological lesions are too grave to be overcome in a large majority of instances.

Although always willing to accord to my professional brethren a full recognition of all their merits, I cannot avoid expressing upon this occasion the opinion that an impartial verdict would not hold some of them excusable for persistently ignoring the iconoclastic spirit of the last decade and a half, and who still regard calomel as their god and veratrum as their demigod, are yet sacrificing at the shrine of the traditional routinist.

Notwithstanding the prophylactic means employed, four of the nineteen cases manifested unequivocal evidences of incipient puerperal fever; three upon the second day and one upon the beginning of the third day of their confinement.

The abortive treatment was brought into requisition at the very earliest manifestations of the disease, and with decisive effect.

Quinine is the remedy *par excellence* in the abortive treatment of puerperal fever. It neutralizes any toxic action from malaria already in the system; it diminishes pyrexia; it slows the pulse, prevents the formation of pus, and is inimical to the existence of bacteria. Ten grains every four hours I have found to be sufficient, although in one case I gave twenty grains to start with, and with the happiest results, and at the end of twenty-four hours in all four of the cases everything was pleasant and satisfactory. In addition to the above, although I have had no experience with them, I would recommend the use of salicylic acid, both locally and internally, and also the use of thymol. It is my candid conviction, that if these suggestions are implicitly carried out, epidemic puerperal fever will be disarmed of its terrors.

As a corollary to the above, I will formulate the chief points for practice.

- 1st. The most scrupulous cleanliness must be observed by all concerned.
- 2d. Unremitting vigilance on the part of the physician.
- 3d. The antiseptic treatment by carbolated oil, and by salicylic acid and by thymol.
- 4th. The early condensation of the uterine walls by means of ergot.
- 5th. The thrice daily employment of the thermometer.
- 6th. Large doses of quinine in the incipiency of the disease.

MOBERLY, Mo., July 10, 1875.

THE MOST UNKILLABLE MAN ON RECORD is said to be one described in the *Medical News*. He fell sheer two hundred and fifty-eight feet by actual measurement, and suffered concussion of the brain, broken ribs, fracture of a radius, and dislocation of a humerus downward and backward. About twenty-four hours after the accident all symptoms of concussion passed off, but an attack of pneumonia followed, from all of which, having made a good recovery, he is as well as ever.

TREATMENT OF CORPULENCE.—Dr. Lucca, Resident Physician at the Marienbad, Bohemia, claims to have astonishing results in the treatment of corpulence, by mixing two or three pounds of common carbonate of soda with a bath of Marienbad water, at a temperature of 60° to 70° Fahr.; one to be taken daily.

Progress of Medical Science.

A CASE OF DOG BITE.—Dr. Theodor Dreschke, of Dresden, reports the following case of *lyssa humana*. It concerned a boy twelve years old, who was bitten on May 26, 1874, by a rabid dog; the wound, which was on the upper lip, being so trivial as to be imperceptible on the following day. Nothing was noticed wrong about the boy until noon of August 12th, excepting some sluggishness of motion and irritability of temper for the preceding three weeks. At the time indicated he suddenly developed an inability to swallow liquids. The next day he was exceedingly restless, and his mind wandered. He was then brought into the hospital. The following morning he dipped a sponge in water, and washed his head and neck, but carefully avoided the mouth and nostrils. He was, however, totally unable to swallow a spoonful of coffee, the attempt causing the most violent spasms in the throat. It was noticed that the same effect was also produced when he was touched about the right nostril, though he was sensitive in no other situation. Early on this day he was in full possession of his senses, but he became wildly delirious late in the afternoon, and died about midnight after an hour's quiet. There were at no time any tonic convulsions or symptoms of paralysis. He had some food during the day; was given a steam bath in the afternoon, and two hypodermic injections of morphine. None of these remedies seemed to produce any effect. The autopsy was made ten hours after death by Dr. Birch-Hirschfeld. The brain was the seat of the most intense hyperæmia and injection, accompanied by great softening of the substance, features which were also marked in the spinal cord. The autopsical record, which is remarkably full, does not seem to show that there were any other lesions to which the symptoms might have been attributed, though it is said that there were four rows of narrow erosions of the mucous membrane of the posterior wall of the stomach. Besides the points to which we have called attention, it should be noticed that two other persons were bitten by the same dog on the same day. In both of these the wound was considerable, and bled freely. One had the wound cauterized three days after it was received; the other had the scar excised the day the boy was taken sick. Both of them are still perfectly well.—*Archiv der Heilkunde*, 16, iv.

EXPERIMENTAL INVESTIGATIONS INTO THE OCCURRENCE OF EXTRAVASATIONS OF BLOOD IN THE MUCOUS MEMBRANE OF THE STOMACH.—Schiff has shown that hemorrhages into the mucous membrane of the stomach take place after injuries affecting certain portions of the brain, notably the thalami and pedunculi cerebri. Following this lead, W. Ebstein has now found this same result from injuries of other parts, also of the central nervous system, viz.: of the anterior corpora quadrigemina and of the spinal cord down to the lumbar portion of it, diminishing, however, the lower down the injury has been inflicted. The same occurred also after continued irritation of sensitive nerves, after injury inflicted on the labyrinth of the ear, and after increase of the blood pressure. In this increase of blood pressure, in fact, as caused by the various experiments, Ebstein finds the explanation of all these hemorrhages. Obersteiner also remarks in noticing these experiments, that hemorrhages into the stomach, ecchymoses of its mucous membrane, and also ulcers of the stomach, are frequent accompaniments of various brain diseases, especially the acute ones.—*Rundschau*, May 25, 1875.

THE MEDICAL RECORD:

A Weekly Journal of Medicine & Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 21, 1875.

THE HOMŒOPATHIC HOSPITAL FOR NEW YORK.

THE homœopathic practitioners of this city and their friends have succeeded at last in obtaining a hospital. By reference to another column it will be seen that the Commissioners of Charities and Correction have set apart a portion of the Inebriate Asylum on Ward's Island for that purpose. It should be a matter of no small congratulation to such as are specially interested in the prosperity of the institution and the success of Hahnemannic practices, that, as a building, it is so admirably appointed. This is as it should be, and we are glad that the concessions have been made, to the end of giving our homœopathic friends what they have always contended they should have, a chance to practise their peculiar doctrines. In fact, we should allow them everything, rather than the opportunity of constantly croaking over their sufferings, their persecutions as martyrs to an opinion. There is nothing that strengthens any cause more than unreasonable opposition to what may even be its pretended claims; nothing which appeals to any notion of ordinary justice more effectually than intolerance of opposite opinions. Whatever may be the real claims of homœopathy as a practice, the foundation of the greater part of its apparent triumphs has been laid in our bitter and foolish opposition to its doctrines. At once the cry of persecution was raised, and it was by no means hard to convince the community that such persecution was not altogether unconnected with interested motives on our part. The sooner we can correct any such impression the better able will we be to combat error, on the common ground of reason and the broad platform of enlightened liberality. That we have made a serious blunder in not doing so before, is now quite apparent to all who are anxious that the community at large should place the proper estimate upon our abilities as practitioners of medicine. The homœopaths have never tired in charging us with persecution, illiber-

ality, narrow-mindedness, and all those elements of character which are hardly complimentary to our reason, common sense, or ordinary discretion. They have said that we have used our influence against all efforts at progress on their part, and are particularly fond of exemplifying on their own behalf that truth and right will always prevail. In fact, they have almost entirely appropriated the familiar lines of Bryant bearing upon this point, and the community naturally expect us to clank our chains in applause of the sentiment.

Within the past few years the doctrine of the survival of the fittest has gained much ground, and its tenability has so forced itself upon the popular mind that it is perfectly safe to rest the issue of opinion upon it. In this view the establishment of a homœopathic hospital is a step which we have no reason for regretting, as being one of the means to the end, which must sooner or later come.

The difference of opinion concerning homœopathy has rested principally upon the *modus operandi* of medicines, and the peculiar treatment which the followers of this absolute system uphold. Now the way to exemplify the boasted brilliant results of their treatment is to satisfactorily settle many of the conditions which modify any system of medication. One of the most important of these conditions is a satisfactory diagnosis of the disease and its particular type of severity. This, it strikes us, would be the fair starting-point of comparison of results, for without it there would be no chance whatever for any just or reasonable conclusions. The existence of a disease, and the pathological lesions connected with it, are facts—self-evident propositions—which lie at the very foundation of all theories, and are the natural bases of all argument for their support.

It is claimed by the homœopaths that in matters of diagnosis and pathology we are their masters. If they are unwilling to take back their oft-repeated assertion, they should concede us the right of aiding them in their endeavors to start aright; in other words, they can lose nothing by allowing us the privilege of making a diagnosis for them, and verifying its correctness by autopsical examination, in case their treatment should ever result disastrously to the patient. Under the government of the same board that manages Bellevue and Charity Hospitals a very satisfactory arrangement can be made to accomplish the purpose. Indeed, we understand that a plan having such an end in view is already under contemplation by the Commissioners of Charities and Correction, and if it be consistently, conscientiously, and honestly carried out, the establishment of the homœopathic hospital may be the beginning of the end of a controversy which has lasted altogether too long, and which has so seriously damaged true progress in medicine. We believe with the homœopaths that there is but one God in medicine; but it is not quite clear to us that Hahnemann is his prophet. Let us, however, in the

spirit of humility patiently listen to what they claim to be their infallible argument.

THE SMALL-FEE SYSTEM.

OUR correspondent who signs himself "A Country Practitioner," in commenting upon the small-fee system, writes a very interesting and suggestive letter. There is no doubting the fact that there is much abuse of medical charity, by not only a wilful neglect to receive small fees, but what is infinitely worse, placing a premium upon dishonest practices. We are constantly hearing complaints from practitioners, in the vicinity of the city, against the questionable means which the different college clinics have of securing interesting cases. It is time that this evil should be remedied by those who have it in their power to do so. There are enough needy patients who could be used for purposes of clinical demonstration, and, generally speaking, if sufficient care was exercised, there would be no difficulty in sifting out the unworthy ones. Mistakes may be made now and then, but there is no reason why they should be so frequent. The enthusiasm for a given college is well enough, but no one but the professor himself would excuse the outrage of actually stealing a patient on such a plea.

Reviews and Notices of Books.

ELEMENTS OF EMBRYOLOGY. By M. FOSTER, M.A., M.D., F.R.S., Fellow and Prælector in Physiology, Cambridge, and FRANCIS M. BALFOUR, B.A., Fellow of Trinity College, Cambridge. London: Macmillan & Co. 1874.

MR. FOSTER'S share in the *Hand-Book of the Physiological Laboratory*, prepared by the joint labors of himself, Drs. Burdon Sanderson, Klein, and T. Lander Branton, is a sufficient guarantee for the practical efficiency and thoroughness of this new volume. Like the hand-book, this is less a treatise than a manual, intended to initiate the student into the personal observation of the elementary facts of embryology; and all thorough helps to such initiation are invaluable, both to those who wish to learn, and to those who wish to acquire the reputation of knowledge by the facile process of reading about what others know.

The present volume of the "Elements" is limited to the study of the chick's embryo, during the first six days of development. This study is intended to be an introduction to the general facts of vertebrate embryology, for which the hen's egg is selected on account of the practical advantages which long ago commended it to Aristotle, to Harvey, "on account of its great cheapness, which puts it in every man's possession;" to Haller, wherewith to prove the doctrine of evolution; to Wolff, in order to overthrow evolution by epigenesis, and to Von Baer, as furnishing material for the entire development history (*Entwickelungsgeschichte*) of animal life.

Mr. Foster declares of Von Baer that "he found the true line of inquiry already marked out by Wolff, and followed it so sedulously, and with such success, that

nearly all the work which has been done since his day up to the present time in vertebrate embryology may be regarded as little more than an extension, with corrections, of his observations." Wolff, in the *Theoria Generationis*, published 1759, laid the foundations of modern embryology, and even of modern histology, when he disproved Haller's theory of evolution by showing that the cicatrula of the hen's egg consisted of cells, and that no embryo appeared in it until after fecundation. The next great epoch consisted in the discovery by Purkinje of the germinal vesicle in the fowl's ovum (1825), and this led to the third (according to Foster the last), namely, Von Baer's discovery of the mammalian ovum in 1827, which first rendered possible a consistent view of mammalian generation.

The study of invertebrate embryology, however, has during the last few years produced the most striking results, and to its main facts, and to the discussion of general morphological considerations, will be devoted the third part of Mr. Foster's "Elements." In the second part will be considered the embryonic histories of other vertebrates, in so far as these differ from that of the bird, and also the development of special organs.

The first part contains, in an appendix of twenty-eight pages, minute practical instructions for studying the development of the chick. These comprise descriptions of incubators and their management; method of opening the egg after eighty-six hours' incubation (period recommended as most suitable for the first studies of a beginner); examination of the blastoderm *in situ* with the naked eye or with a lens; removal of the embryo, and preparations for observation at a low power of the microscope; details of the surface view of the transparent embryo, as seen from above and below; and examination of the embryo as an opaque object. Then follow directions for preparing sections, with methods for hardening, staining, and imbedding. Analogous indications are given for the examination of an embryo at forty-eight hours, on the fourth day—at twenty hours—finally of the incubated blastoderm.

The main part of the book, however, is occupied with a didactic description of the successive changes that may be detected by the foregoing manipulations. Such descriptions, detailed from day to day, read like the first chapter of the book of Genesis, with the additional marvel of being both true and verifiable by one's own eyes. On the first day the blastoderm is divided into three layers—the epiblast, mesoblast, and hypoblast, or the serous, mucous, and intermediate layers, as they were formerly called. The primitive streak is formed by a thickening of the mesoblast, the primitive groove along its centre, the medullary groove in front, while below the latter the notochord is formed out of mesoblastic cells. The primitive groove, supposed by earlier observers to be converted into the medullary canal, is now known to disappear without apparently fulfilling any function whatever. "We can only suppose that it is the rudiment of some ancestral feature." The rudiments of the vertebral column appear in the first day, where one or more pair of protovertebræ rise on each side of the notochord (chorda dorsalis.*). The mesoblast is split in two; the upper half unites with the epiblast to form the somatopleure, destined to generate the external part of the body; the lower half unites with the hypoblast for the formation of the viscera. Between the two lies the great pleuro-peritoneal cavity. This cleavage was

* See Robin, Mémoire sur l'Evolution de la Notochorde, 1868.

described by Von Baer as a process by which the different layers of the embryo were transformed into a series of concentric tubes, or fundamental organs. The innermost of these is the mucous membrane; the next the vascular layer of the abdomen. "Finally, an outer animal or flesh layer (*Fleischschicht*), which forms a posterior tube,—the vertebral column surrounding the nerve-tube, and an abdominal tube inclosing the two first named.*"

Finally, on the first day of development in the chick, appears the headfold and first trace of the amnion, and the vascular area begins to be distinguished from the rest of the opaque area.

On the second day the medullary folds close around the medullary groove, and form the neural canal; the head is elevated above the plane of the blastoderm; the heart and great blood-vessels are formed, and the rudiment of the Wolffian duct. This during the first half of the day. During the second half the second and third cerebral vesicles appear, as also the optic vesicles and vesicles of the cerebral hemispheres, both head and tail are more definitely formed, and the amnion grows rapidly.

On the third day new viscera appear; the foregut is divided into œsophagus, stomach, and duodenum; the latter into large intestine and cloaca; the lungs bud out as diverticula from the alimentary canal; the liver and pancreas as diverticula from the duodenum. The cranial nerves appear, not continuous with the cerebral vesicles, but developed independently in the mesoblast. The four visceral clefts—of which the upper one becomes the mouth, while the lower are ultimately obliterated—appear between the five visceral folds. Of these the upper one divides into the superior and inferior maxilla, the second develops to the hyoid bone, the remaining three become the temporary branchial arches.

The most important event on the fourth day is the development of the genito-urinary system from the Wolffian duct and body, which had existed alone from the second day. The generative glands in both sexes arise from the inner border of the Wolffian body, on a ridge consisting of cylindrical epithelium, derived from the hypoblast of the splanchno pleure, or the abdominal cavity, or nutritive epithelium of the ovary. Among the mass of epithelial cells some are larger than the rest, and become the primordial ova. These exist up to the eightieth hour, in the male as well as the female embryo, then the first differentiation of sexes takes place, by an arrest of development of this epithelium in the males, while in the females it becomes more and more prominent, and grows to the Graafian vesicles. In the females, also, the oviduct is derived from the duct of Muller, which is developed on the outer border of the Wolffian body by an involution of the germinal epithelium from the pleuro-peritoneal cavity. The vas deferens, on the other hand, the masculine analogue of the oviduct, is the excretory duct of the Wolffian body, which persists in the male and atrophies in the female. The kidney, like the Wolffian body, makes its first appearance on each side as a duct, given off as a diverticulum from the Wolffian duct, about the eightieth hour, or coincidently with the differentiation of the sexes. This duct, the permanent ureter, again gives off numerous diverticula from its upper end, which, lengthening and becoming twisted, form the tubuli uriniferi, around which the mesoblast condenses into the malpighian bodies. In this account of the primitive development of the genito-urinary apparatus Foster entirely agrees with

Waldeyer. These, as all modern researches, entirely disprove the opinion, so prevalent a few years ago, that the female organism represents an earlier, more immature type than the male. It is evident, on the contrary, that there are no successive stages of development by which the one sex passes into the other, but that both are evolved by equivalent differentiations from a common neutral sexual organization.

The other most important event of the fourth day is the projection of the allantois from the pleuro-peritoneal cavity. The allantois is to be regarded as a portion of the cloaca, but on the fifth day, when it grows very rapidly, it is to be considered as chief organ of respiration. On the fifth day limbs grow, and wings become distinguished from feet, the knee and elbow joints appear, and cartilaginous rods in the visceral folds, also in the limbs. The digestive canal is developed by the formation of the anus; the spinal cord acquires a large development of gray matter in the cornua, and the white columns grow; while in the vascular system the most important epoch in the history of the heart occurs. The ventricular septum is complete, the auricular septum appears, the bulbus arteriosus is also divided, and the semilunar valves are formed.

Finally, the sixth day marks a new epoch in the general development of the chick, for then are first seen distinctly avian characters. Then for the first time become visible the main features of the characteristic manus and pes; the crop and intestinal cæca; the stomach takes on the form of a gizzard, the nose begins to develop into a beak, and the commencing bones of the skull to arrange themselves after an avian type. On the sixth day Von Baer observed movements of the limbs, and on the seventh Vulpian discovered rhythmical pulsations of the amnion, which he ascribed to rhythmical waves of nutrition.*

The remaining history of the chick's intra-ovular existence is more briefly sketched. Since facts and theories of development to-day influence every department of human thought, and of none more than the sciences pursued by the physician, practical acquaintance with the elements of embryology and methods of embryological research becomes of constantly increasing importance. Hence the great value of a volume like the one whose contents we have so briefly indicated, which not only guides the beginner, but by the discussions of controverted points inducts him gradually into the central regions of high and most modern science.

MANUAL OF HYGIENE. By CHARLES H. CAMERON, Ph.D., M.D. Dublin: Hodges, Foster & Co. London: Baillière, Tindall & Cox. Nov., 1874.

This manual is among the recent valuable contributions to sanitary science. It is an attempt to furnish such a guide and such information as will be of service to health officers, and also aid those who are engaged in direct scientific investigation. The book, both in its commencement and its appendix, gives us an idea of the progress of health legislation in the United Kingdom. Its opening sentence informs us that "the Public Health Act of 1874 has created a permanent army of sanitarians for Ireland." Further on we are told that every part of the United Kingdom is now provided with health officers. Nearly one-third of the volume consists of a collection of thirty-four sanitary statutes applicable to Ireland. These include most of the subjects which come under the surveillance of sanitary law, and are well worthy of the examination of framers of health codes.

* Entwicklungsgeschichte der Thiere, p. 165.

* Journal de Brown-Séquard, Vol. I.

The author in his introduction plainly comprehends the sphere and extent of sanitary science. He well remarks that physicians mistake in assuming themselves to be sanitarians because of their profession. There is need to acquire more of the knowledge of the physicist and the political economist than belongs to a study of the treatment of disease. The second chapter treats of the duties of health officers. The importance of house-to-house inspection is wisely brought into prominence. In Chapter III., on nuisances, the author specifies overcrowding, privies and ash-pits, cellars, housed animals, manure, black smoke, effluvia from factories, and steam whistles. The list is not very complete, but valuable suggestions are offered. The next chapter, on vital statistics, illustrates anew how vital is the study of this department, and how imperfect it still remains. We need to study not only death rate, but sickness rate and birth rate. There are many insidious sources of error to be eliminated in our calculations. The real expectation of life is often quite different from the tables. Approximate figures often have very little of pure mathematics in them, and the balancing of errors does not furnish exact results. We confess ourselves unable to accept many of the conclusions of statisticians, because objecting to their mode of averaging.

On the question of marriage between relatives. Dr. Mitchell, of Edinburgh, is quoted, and the danger stated to be in the increased risk from such marriages "of the transmission of abnormal peculiarities." It is well to remember that if a perfect son and daughter of Adam and Eve had been joined in wedlock and had begotten children, they were quite as likely to be perfect as their parents. The mere fact of the same blood is not contaminating or deteriorating, except as similar and real defects are multiplied, and these, like family traits, are apt to be similar in relations. The whole subject of heredity will bear restudying in the light of new physiological research.

From Chapter V. to IX. we have a presentation of facts as to water supply. Directions are given with exactness as to the tests for water and its filtering. A chapter on water as a carrier of disease gives many instances to show its agency in this regard. Chapters X to XIII. treat chiefly of air and heat in their relations to health. As usual, there are some indefinite suppositions as to ozone in its bearing on epidemics. The author states that it is "used up in the open country in destroying the organic matters which are so abundant in such situations." The only evidence of this adduced is that where there is much organic matter in decay there is generally not much ozone. The test of carbonic acid in air by baryta water is commended for its simplicity. But it must be remembered that too much significance must not be given to the presence of carbonic acid as the full test of impurity. The more deleterious organic ingredients of foul air are not always in proportion to the carbonic acid. The author well remarks that headache and other pains which we suffer from ill-ventilated places are nearly altogether owing to the organic matter, and not to the carbonic acid of the vitiated air. The nitrogenous organic matter is so insinuating that filtration through cotton wool does not remove it.

In the chapter on Heat it is recommended that air from a furnace should never be admitted to rooms. For the introduction of fresh air to a room, Gauger's plan is approved, which is to have an air-chamber back of the fireplace and flue, communicating on one side with the atmosphere, and on the other with the room. The air is thus heated and delivered fresh and warm into the apartment. The amount of oxygen ab-

stracted from the air by lights and fires is alluded to, also the importance of avoiding red heat and dampers.

The relation of the ground to health is well discussed in Chapter XIII. It is important to recognize the different capacities of different soils as to moisture and as to the disposal of the varied products of decay. Air beneath ground is richer in carbonic acid than the atmosphere, and may contain offensive gases. "A strong wind playing upon the surface of the ground outside a house has been known to force the gases contained in the ground into adjacent houses."

The introduction to the chapter on contagion makes us feel more than ever how, as a profession, we need to come to a more definite understanding in the use of such words as contagion, infection, etc. Our author says these words are used indifferently, and mean "catching," while Dr. Erskine, in his excellent report on yellow fever in Memphis (*Public Health*, Vol. I.), says yellow fever "is not contagious, but its fearfully infectious character is beyond dispute." The author gives some important thoughts as to microzymes in their relation to disease, and wisely regards the germ theory in reference to zymotic diseases as still *sub judice*. The chapter on vaccination affords new proof that we still have a wide field for study and observation in this department. The recent outbreak in Ireland, after variola was supposed about banished, shows how eternal vigilance is the price of liberty. The impossibility of transmitting other diseases through vaccine virus is strongly stated. The chapter on disinfectants and deodorants is one of the best, not because it introduces to us new antiseptics, but as fairly presenting the basis of their use, and the results of the careful experiments of Dougall, Calvert, Plugge, etc. The hot-air disinfecting chamber which the corporation of Dublin provides for disinfecting clothing and bedding is a valuable arrangement. It is important for the unwashed woollen clothing worn by laborers as well as for that infected by disease, and the expense of use is small.

The chapter on the spread of disease and how to prevent it has many facts pointing to the specific character of contagions. We should like to know on what authority the author says, "It is probable that attacks of such comparatively mild zymotics as measles may help to render persons somewhat less susceptible to the poison of all the contagious maladies." If there is respectable evidence of this we should be glad to have it. If not, we object to mere guesses from eminently respectable authors, lest their random hypotheses be quoted as verities from the respectability of the source. We need some facts or scientific probabilities to support such suggestions. Hospital Ventilation is well treated, and the chapter well summed up by the remark of Simon that "what makes the healthiest house makes likewise the healthiest hospital." A chapter on school hygiene draws timely attention to the evils resulting from imperfect school methods and arrangements. Both Chadwick and Virehow have given us able treatises on this subject. The sewage question is quite fully discussed. The author gives in his adhesion to the water system as best adapted to dealing with human excrement.

The question of utilizing sewage is discussed at some length, but properly held in abeyance to the best methods of securing its removal in the interests of health. It is a good remark that "excrement may be removed from towns, and safely disposed of on more than one principle, and the same principle does not need to be applied in all quarters of the same town."

The effect of occupation upon health is discussed in two chapters.

Exercise, bathing, and clothing are discussed with the usual amount of good advice.

The mind, like the body, it is said, can be underworked as well as overworked. We think this view of mental hygiene needs to be considered in its bearing upon some classes.

We have great respect for Sir Alfred Power, because he seems to have done much for the relief of the poor and the improvement of the public health, but we trust his poetical effusions will not be numerous.

The chapter on foods is full of well-considered suggestions and facts. We must except the strange advice of page 274, where rusk-panada, weak beef-tea, and chicken broth are recommended for healthy children, after two or three months. This is too early to depart from the special indications of maternity. The chapters on diseased food and on adulterations of foods and drinks, draws attention to most of the modes of detection and give valuable caution. While there is not very much new matter in the book, the old is well collected and arranged, and the author evidently has high claims as a practical sanitarian. It is what it seeks to be, a manual, and deserves to take a place among the valuable aids to sanitary science, and as a guide in sanitary legislation.

THE NATURE AND TREATMENT OF VENEREAL DISEASES. By ROBERT A. GUNN. New York: A. K. Batts & Co. 1875.

The reader of this book will undoubtedly be struck with the fact that while upon the title-page the author speaks of venereal diseases, in the body of the volume he considers that there is but one venereal disease. The present work affords a poor example of a man stultifying himself to the results of modern careful and convincing research, and of maintaining views which have been scientifically proved to be incorrect years ago. We shall not go into the author's reasons for his peculiar opinions, as such a course would require a discussion of a question which has long been settled, and, we think, forever. The author evidently is influenced by the results of a small field of observation, and as it is to be feared that he is lacking in the knowledge of certain facts relating to the true virus of syphilis and of the pus of chancreoid, he forms the opinion he entertains, the truth being that if the very cases which have convinced him were examined and explained according to well-known facts in syphilology, they would be powerfully convincing of the errors of the construction placed upon them by Gunn. We should strongly advise the author, if he ever has the happiness of bringing out a second edition, to study more carefully the features of both hard and soft chancre, and to examine into the doctrinal points as to the origin of chancreoid pus, as well as the results of the numerous experiments which have been made with it. The author's descriptions of the various lesions of syphilis betray a want of large familiarity with them, so that, even if based upon the words of classical writers, they have suffered in the translation. In keeping with other parts of the work, the chapter relating to the treatment of syphilis is disappointing. The vegetable remedies advocated have long been tried and found wanting, and the author's arguments against mercury are not his own, nor are they convincing. It were better that such books were not written, for it is questionable whether the stock used in getting them out would not have done more good in the rough.

OZENA AND ITS TREATMENT. DE L'OZÈNE ET DE SON TRAITEMENT. By A. D'AZAMBUJA. Paris: Delahaye. 1875.

This affection, often one of the most inveterate, is, strange to say, not very often made the subject of study and didactic treatise. The present author has evidently devoted much time and thought upon its clinical history, and his descriptions being good, he has produced a very acceptable brochure. He considers first the nature of the complaint as a symptom, its diagnostic points, and finally its treatment. He thinks that chronic fetid coryza or coryza should be divided into: 1st, the simple non-ulcerous coryza; 2d, the ulcerous form; 3d, the necrotic; and 4th, the caseous.

Each of these are well described and illustrated by cases. As to the simple form, he, like most French writers, thinks that it is a manifestation of an herpetic or dartrous diathesis. Azambuja's remarks upon diagnosis are very pertinent; indeed, considering how little this subject has been studied, they may be pronounced *clever*. He thinks that in a given case the attendant should try to ascertain: 1st, is there an ulceration? 2d, what is its depth? and 3d, what is the nature of it? Each of these questions is carefully considered, and the text offers some important suggestions. In the matter of treatment, the author goes over the usefulness of many remedies and modes of procedure, and, while he gives a fair résumé of our knowledge, makes some good points. He makes a digest of his book in seven aphorisms. They are as follows:

1. Ozena is a chronic fetid coryza; in other words, to be a coryza there must be chronic inflammation of the pituitary membrane or of the subjacent tissues, and a fetid condition of the breath.

2. It is almost always of serofulous or syphilitic nature; rarely it exists without known cause, resulting from traumatism, the presence of foreign bodies or calculi in the nasal passages, or arising from destructive lesions, happening as a complication during the decline or in convalescence of adynamic fevers. More rarely still, it is an evidence of herpeticism.

3. There is a simple, non-ulcerating ozena, and a fetid coryza without ulceration. The latter shows itself in two forms, the moist and the dry. It is the result of serofula, and it is very doubtful whether syphilis plays a part in its causation.

4. There is an ulcerating ozena without osseous lesions, caused either by serofula or syphilis. The ulcerations of serofula invade the superficial structures and then the deep, being more irregular than those of syphilis. Syphilitic ulcers are caused by two different processes; first, by symptoms similar to those of the skin; second, by the softening of the gummata.

5. The most serious form of ozena is that which begins in the bones—the necrotic form—and is more frequently due to syphilis than to serofula.

6. Ozena always accompanies the affection described as caseous coryza.

7. The treatment is both local and constitutional, the latter being required in syphilis and serofula. The best method of local treatment consists, 1st, in douches and irrigations; 2d, in direct cauterization of the ulcerations.

The author refers to a method of reaching the nasal cavities, devised by Rouge, of Lausanne, which, while it gives good results, has numerous drawbacks, and is sometimes followed by death. It consists in incising the gingivo-labial angle. Separating the soft parts of the nose, and throwing them back, the fossæ are reached. The parts are afterwards replaced without deformity.

Correspondence.

THE SMALL-FEE SYSTEM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Your editorial on "The Small-Fee System," recently published in THE MEDICAL RECORD, touches a number of points which cannot fail to interest many professional brethren who have been waiting for some one to present an old case in a new aspect.

I have long been in the habit of receiving small fees from many of my patients, I being in the capacity to them of a physician to a sort of protective union, or, more properly, the medical attendant of a factory in which these people are employed. Many of these employes have left the mill, and in other callings have still continued to employ me as their physician under what you please to call the "small-fee system." I doubt not that there are not a few medical men who, while they may openly condemn the "small-fee system," secretly take advantage of its benefits.

The difficulty with each physician is to decide who may be the ones in his practice who may be entitled to the benefits of the new system, the object being to aid the honest man in discharging what he believes to be a debt of obligation. Too great care cannot, in my opinion, be taken to guard against the deception of the so-called professional frauds. But each medical man must make his own standard in this matter, and be willing to draw his own line of distinction.

The bad influence which small fees may have upon the abuse of medical charities is, I think, very much overrated. One fails to see how it can possibly affect a poor but honest patient in any other way than for good. He is made to feel more or less free from pecuniary dependence, and is the farthest possible removed from the person who glories in cheating the doctor. Altogether, it is one of the best ways to prevent this professional pauperism which has been fostered by the high-toned sentiment against small fees, and by the determination to take large fees or none at all. If you make a patient believe in such a doctrine, make him think that when he cannot pay the standard fee that he is entitled to any of our services free of expense, then you spoil him for all time, and he either feels insulted at any reasonable bill, or he goes to the dispensary or college clinique, to eke out a shameful pauperism.

While speaking of the evils of dispensaries, college clinics, and the like, it is not fair to make the would-be pauper-patient bear their whole weight. If medical men in charge of these institutions did not encourage the practice, there would be no need for this outcry against the abuse of medical charities. As you have on previous occasions very truly said, the leading men and medical teachers have placed such a premium upon medical pauperism that it is now almost next to impossible to stem the tide of the abuse of our medical charity. There is not one bit of exaggeration about this.

I was most struck, not long since, by a communication from a rural practitioner, who complained that a good-paying patient of his went to one of the New York college clinics, and was operated upon for nothing, and without question, by one of the leading practitioners in your large city. When I was a student I knew this to have been done repeatedly. One of the wealthiest men in my section of country, at the time a patient of my preceptor, went to the city for

the purpose of seeing an eminent surgeon, and having lithotomy performed. I give him the credit to state that he (the patient) went with the best of intentions, but some how or other he learned that he could have the operation performed for nothing at one of the colleges. I well recollect with what a chuckle of satisfaction he told me of the arrangements for the said operation, and how it pleased his miserly soul to call himself a fool for paying for a thing which "these great men in New York seem so glad to give for nothing." "Why," said he, "I have no doubt they would pay me for letting them do it, rather than cheat the young doctors out of a little show." The operator was informed of this fact; but he told me that, after all, the operation would do more good to the college than to the patient, and so it was done—done, when the patient could well afford to pay five hundred dollars for it, and would have been performed by my preceptor, only he wished to give the patient the best possible chance of extended consultation in the city, because he was well able to pay for it. This is an instance of what I call putting a premium on professional frauds. It is from these seats of learning that we get all our ideas of professional ethics, and we hear from their professors that if a man does rightly, he will be sure to succeed; that we should never cheat each other out of practice; and yet these very leaders of professional thought do the very thing above all others which has a tendency to take the very bread out of the mouth of the young medical man, who has a need for every crumb.

A parallel instance occurred to me after I had graduated and had settled for a time in New York. I had a case of popliteal aneurism in a comparatively well-to-do mechanic. I agreed to operate upon the same by ligation of the femoral. The patient agreed to pay me fifty dollars for it. While I was getting ready to perform the operation, the man had, some way or other, drifted into one of the college clinics. The case was an interesting one, and the surgeon marked the man at once. Of my personal knowledge, this surgeon afterwards drove to the house of my patient, and not only solicited him to come to the college to have the operation performed, but actually promised him a place in a hospital afterwards, where his board and attendance should be free during his convalescence. My patient could not resist the plaintive appeal, and I lost him. I certainly could not blame him; for here was I, a youngster, on the one hand, who wanted fifty dollars as much as I ever did in my life, and who was to perform the operation because that fifty dollars was one of the prime inducements; while, on the other hand, there was an eminent professor and expert, who had a very large experience, and who not only promised to do the operation for nothing, but virtually pay the man's board besides.

These are matters which have come under my professional knowledge, but I have heard of others which are even worse. I have been informed by a trustworthy gentleman that he knew of a patient who was "well off," and was actually paid in money by a professor who wanted to perform lithotomy upon him before a college class, and that the patient accepted the money as a *quid pro quo*. The circumstance at the time was made quite public, from the fact that a rival medical college, which was also anxious to get hold of the patient, hearing that twenty-five dollars had been offered to the "man with the stone," promised to give him "fifty dollars" if he would be cut at their college. From some strange reason the man very disinterestedly stuck to his original contract.

I admit that these are extreme cases; but we have

similar ones, though less in degree, that are constantly crowding our college clinics and dispensaries, and that do so because many men send them there rather than take a small fee, a fee which the patient would esteem it a privilege to pay.

Now, it strikes me as preposterous to assume that because services cannot command so much, that they are worth nothing. This would be a strange law to apply to trade, and yet the poorest of all trades—the practice of medicine—acknowledge it as a leading principle. I have never heard of a business-man giving away his goods because he could not get a fixed price for them. Somehow or other these men strike a cash balance between what they ought to have, and what they can get, and in the end become rich. The doctor, on the other hand, places himself above the petty consideration of cash compromises, and generally dies a poor man. I for one do not think that this false pride, this unbending dignity in regard to standard fees, this refusal to take smaller ones when we cannot do better, pays in the long run.

A COUNTRY PRACTITIONER.

A PROPHYLACTIC FOR SORE NIPPLES.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The curative as well as the palliative treatment of sore or cracked nipples being well known to be futile, my aim for a long time was directed to the finding of a *reliable prophylactic*. After trying a good many formulas of others, and combinations of myself, I came at last to the use of "*tannate of lead*," the "*cataplasma ad decupitum*" of the Pharmacopœia Germanica, with the addition a little glycerine to modify, in some degree, the excessive drying properties of that preparation. This "*plumbum tannicum pulviforme*" I had applied, for about one month before parturition, two or three times a day, directly to the nipples. This, I found, "*TANNED*" the nipples in so thorough a manner that they were perfectly able to withstand all suckling and all pulling on the part of the infant successfully. At the same time I use a piece of *cotton felt*, about one and a half inches in diameter, and half an inch in thickness, with an aperture in the middle large enough to give free access to the nipple. This will not only prevent the pressure of the garments on the nipples, but will give, at the same time, to the nipples a chance to develop themselves better, which is often so much needed.

JULIUS FEHR, M.D.

HOBOKEN, N. J., June 5th, 1875.

ACID TANNATE OF IRON IN DIPHTHERIA.

EDITOR OF THE MEDICAL RECORD.

SOME time in August last my attention was directed to an article in the *Physician and Pharmacist*, by Dr. J. A. Hopkins, of Milton, Del., regarding the local use of the acid tannate of iron in diphtheria. Though the disease has not been very prevalent throughout my immediate neighborhood since, my experience with the substance in some six cases has been so favorable as to induce me to second the Doctor in calling the attention of the profession to it as a valuable therapeutic agent. In one case especially, an effect was produced which may be of interest. The patient being a docile, quiet girl, whose tonsils were completely covered with the diphtheritic deposit, I introduced the point of a bistoury, and gave a little slit, by means of which I was

enabled to detach and hold up a portion of pseudo-membrane, about a line in thickness, and having the appearance of "dirty wash-leather." On applying the acid tannate, a rapid apparent coagulation took place, the membrane shrinking from the incision towards the periphery. Nor was it afterwards reproduced to any great extent. In the other cases no such striking result was obtained, but the local disease would appear to be modified, the influence of the agent being attested by the at first blackened and afterwards brownish color of the deposit. Exfoliation generally began in the course of a few hours, in the form of hardened patches coughed up and expectorated occasionally. The method of application which I found best, was to first apply thoroughly the "*tr. ferri chl.*," followed immediately by a strong solution of tannic acid; thus allowing the chemical reaction to take place upon the diseased portion. An application once in the twenty-four hours is, I think, sufficient, due attention being, of course, paid to tonic and stimulating remedies, with disinfectant solution and nourishment.

H. B. WHITEHORNE, M.D.

VERONA, ESSEX CO., N. J.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from August 8th, 1875, to August 14th, 1875.

BACHE, DALLAS, Surgeon.—Leave of absence extended one month. S. O. 45, Head-Quarters of the Army, August 10, 1875.

FORWOOD, W. H., Asst. Surgeon.—Granted leave of absence for one month, with permission to apply for an extension of two months. S. O. 155, Department of Texas, August 6, 1875.

KIMBALL, J. P., Asst. Surgeon.—Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 147, Department of Dakota, August 3, 1875.

MAUS, L. M., Asst. Surgeon.—Assigned to duty at Nashville, Tenn. S. O. 111, Department of the South, August 6, 1875.

TAYLOR, B. D., Asst. Surgeon.—Assigned to duty at Fort Snelling, Minn. S. O. 149, Department of Dakota, August 3, 1875.

KILBOURNE, H. S., Asst. Surgeon.—Assigned to duty at Fort Gibson, Indian Ty. S. O. 139, Department of the Missouri, August 3, 1875.

BARNETT, R., Asst. Surgeon.—Assigned to duty at Coushatta, La. S. O. 145, Department of the Gulf, August 5, 1875.

WOOD, M. W., Asst. Surgeon.—Assigned to duty at Camp Douglas, U. T. S. O. 87, Department of the Platte, August 4, 1875.

TESSON, L. S., Asst. Surgeon.—Assigned to duty at the Military Prison, Fort Leavenworth, Kans. S. O. 143, Department of the Missouri, August 9, 1875.

The following named Asst. Surgeons, recently appointed, are ordered to report by letter to the Commanding Generals of the Departments named, for assignment to duty:—Curtis E. Price, Department of California; H. S. Turrill, Department of Texas; Jos. Y. Porter, Department of the Gulf; Geo. E. Lord, Department of Dakota. S. O. 163, A. G. O., August 12, 1875.

NAVY NEWS.

August 13th.

AMELER, J. M., Assistant Surgeon.—Ordered to the *Minnesota*.

MARTIN, EDWIN M., Assistant Surgeon.—Detached from the New York Navy Yard and ordered to the *Intrepid*.

McMURTRIE, D., Surgeon.—Placed on waiting orders.

Medical Items and News.

THE CHOLERA IN SYRIA.—A correspondent of the *British Medical Journal* writes that in Damascus, from the 5th to the 12th of July, inclusive, there were 1,118 cases of cholera, 506 of which proved fatal. The worst day was the 12th, when there were 190 cases and 107 deaths. At Antioch, from the 6th to the 11th, there were 115 cases and 66 deaths.

CHILD KILLED BY A ROOSTER.—A child in Alabama, aged eighteen months, while playing out of doors, was attacked by a rooster and knocked down. He received several strokes from the rooster's spurs, and one of them entering the skull through an open fontanelle, wounded the brain and caused the death of the child.

CHOLERA IN TURKEY.—Cholera showed itself last May in Hama, a town of 30,000 inhabitants, and about five days' distance from Damascus. The Turkish officials at once took measures to prevent the spread of the disease, but the attempt to maintain a *cordon sanitaire* had to be abandoned, and the disease has been gradually spreading to neighboring towns, and cases have occurred in Antioch, Aleppo, and Damascus. Quarantine exists at Syria and Trieste against all vessels from Syria. A medical commission has been sent from Constantinople, among the members of which are Drs. Millinger and Zitterer. Dr. Dillon, late resident sanitary officer at Mussul, has died at Hama of the disease.

The latest accounts reach us through the *London Times*, of the 7th of August, which publishes a letter from the Secretary of the Universal Alliance, who says: "According to accounts from Damascus to the 22d of July, the cholera was raging there. Four hundred cases were reported daily, but the real number was concealed. The Christian quarter of the place was deserted. Sudden deaths occur in the streets of the city. There are no physicians, medicines, or supplies for the treatment of the sufferers. The disease is also bad at Antioch, Deir Hems, Hamah Hauran, and Salahiya, and among the Druses. The mission schools are closed, and the children have dispersed."

Hamah, where the disease first appeared, is quite out of the track along which cholera has been accustomed to spread in its westward course, and is said to have been introduced by a body of troops coming from Kerbela. The outbreak has followed intense and unusual heat in Hamah, and excessive rain in Damascus.

PLUGGING THE NASAL FOSSA.—A writer in the *Independent* suggests the following procedure in the absence of a canula, sound, or any other instrument. Take a common stout thread, grease it well, then, having rolled one end into a ball the size of a pea, place it in the implicated nostril and direct the patient

to snuff it up. If the plan succeeds, the ball, or what remains of it, is found hanging beside the uvula, and ready for the attachment of the plug.

THE SCHOOL FOR NURSES, which the Commissioners of Public Charities and Correction propose to establish in Charity Hospital, was opened on the first of the month; over thirty applications having been received from women of fair qualification. Besides the course of instruction at the bedside, which is to be conducted by the house-staff, lectures are to be delivered to the pupils by junior members of the Visiting Staff, on Nursing, Midwifery, Physiology, Surgical Nursing, Examination of Urine, Hygiene, Children, Poisons, and Food.

THE UNIVERSITY OF MICHIGAN.—The Regents of the University have appointed Dr. Samuel A. Jones, of Englewood, N. J., to the chair of Homœopathic Materia Medica, and Dr. John C. Morgan, of Philadelphia, to the Chair of Theory and Practice of Medicine. The salary of each is \$1,800 per annum.

THE CONNECTICUT STATE MEDICAL SOCIETY elected the following officers at its last annual meeting:—*President*, P. A. Jewett, of New Haven; *Vice-President*, A. W. Barrows, of Hartford; *Secretary*, M. C. White, of New Haven; *Treasurer*, J. C. Jackson, of Hartford.

HOMŒOPATHIC HOSPITAL.—It is reported in the daily papers that the Commissioners of Public Charities and Correction voted, on the 7th, to place the building heretofore used as an Inebriate Asylum on Ward's Island, under the charge of homœopathic physicians and surgeons, to be used as a general hospital.

The following preamble and resolutions were passed accordingly: *Whereas*, More than six months ago an appeal was made to the Board by six hundred and fifty-five citizens and tax-payers to designate an hospital to be under the care of homœopathic physicians; and

Whereas, The resolution of this Board, passed February 13th, conditionally assigning the Riverside Hospital for the purpose, has proved inoperative by reason of the continued occupancy of that building by the Board of Health; therefore,

Resolved, That that portion of the Inebriate Asylum on Ward's Island, made vacant by the distribution of the soldiers to national homes, be set apart for a hospital, to be under the care of homœopathic physicians, under such rules and regulations as the Commissioners of Public Charities and Correction may establish.

Resolved, That the Committee of the Homœopathic Society, whose petition in this behalf bears date July 3, 1875, and was followed by a personal interview with the Commissioners on the 13th of July, be notified of this action of the Board, and requested to make such suggestions and recommendations as may seem to them calculated to promote the object in view.

THE ROYAL COMMISSION ON VIVISECTION.—Much fault is being found in England with Professor Huxley, for absents himself from the meetings of the Committee appointed to investigate the subject of vivisection. He is the only member of the Committee competent to insure a fair hearing for the scientific side of the question; the only other member who is known to have devoted much attention to the subject having made the statement that it were better that mankind should suffer for generations from curable disease and removable pain, than that animals should suffer in order that the means of curing disease and curing pain should be discovered.

Original Communications.

TREATMENT OF DISEASES OF RESPIRATION AND CIRCULATION BY THE PNEUMATIC METHOD.

By A. ROSE, M.D.,

NEW YORK.

SINCE a certain extensive therapeutical scepticism has disappeared in Germany, there has been an endeavor to determine indications exactly, and to perfect the methods for applying remedial agents. To these rational endeavors we owe the introduction of hydrotherapeutics, electro-therapeutics, gymnastics for orthopædic purposes, inhalations, etc.

A few years ago a new method of local treatment of diseases of the respiratory organs and heart was introduced into medical science, principally by HAUKE, of Vienna, and WALDENBURG, of Berlin, which, on account of its practical importance, very probably occupies the most prominent position amongst the varied attainments of therapeutics at the present time.

It has been shown, especially by the investigations of Waldenburg and Riegel (Waldenburg, *Die Manometrie der Lungen oder Pneumatometrie als diagnostische Methode*. Berlin, klin. Wochenschr., 45, 1871, and Riegel, *Die Athembewegung*. Würzburg, 1873), that the careful observation of the distinct acts of inspiration and expiration is of primary importance in both diagnosis and treatment of diseases of the respiratory organs. According to these investigations it is important to discern whether the condition of dyspnoea depends upon imperfect inspiration or imperfect expiration, or upon both. It was proven, for instance, that in cases of emphysema only the expiration was imperfect; the inspirative force was not only normal, but often even greater than normal, this being the natural result of the excessive use and consequent development of the inspiratory muscles; however, in cases of phthisis, that primarily and principally the inspiration, and later the expiration, is imperfect. Stenoses of the respiratory ducts produce imperfect inspiration, but leave expiration intact. Waldenburg found that in catarrh of the small bronchi expiration was invariably imperfect, inspiration normal; he also observed that inflammation of the lung tissue and of the pleura had an effect upon respiration similar to that produced by phthisis. To mention a striking example, we will find that *such* treatment will directly benefit a patient, afflicted with emphysema, which assists expiration. By this means—as will be seen later—the surroundings of the thoracic cavity (thoracic wall and diaphragm) will, from their permanent inspiratory and expanded position, be reduced to their former condition of equilibrium.

For treating these different imperfections of respiration successfully, a portable apparatus was invented, which was first made known to the profession at large in the year 1870, by Dr. HAUKE, in Vienna, by means of which air in a receiver can be condensed or rarefied, and used in either of these conditions for respiration.

Dr. Von Cube, of Mentone, Italy, found, while investigating the subject, that, two years before Hauke's publication, Dr. Lewess (like Dr. Von Cube, a German physician), in St. Petersburg, Russia, had practised the pneumatic method successfully; his apparatus (bellows and cylinder system) is said to be, in exactness

and completeness of action, not inferior to those which were constructed later and have become more generally known at the present time.

Several of Hauke's apparatus were imported here by Otto & Reynders, and were procured by German physicians; I recently saw one in the store of the firm mentioned. To my knowledge, however, no communications have been published here in reference to this new treatment and of this new invention.

Hauke supposed his contrivance to be especially useful in cases of emphysema and croup. In emphysema expiration should be made into rarefied air; in croup condensed air should be inspired. He soon dropped this treatment for croup, but he was most successful in emphysema. Later he recommends inspiration of condensed air as a prophylactic remedy for consumption, and he relates a case in which a patient in the first stage of phthisis was so far relieved after a course of treatment, lasting three months, that all symptoms of disease disappeared, with the exception of a dulness on percussion and prolonged expiration.

After his publication a number of other physicians, most of them in Vienna, employed Hauke's method, and confirmed in their communications the favorable results. However, taken as a whole, such communications were few until Waldenburg overcame the imperfections of Hauke's invention, which consisted in an insufficient development of power (maximum $\frac{1}{4}$ atmosphere) and inconstancy of effect, and constructed his own pneumatic apparatus. He at first experimented with Hauke's, and afterwards with the one of his own combination, upon healthy persons and patients, and arrived at a conviction stronger even than any of his predecessors in this treatment, that the fundamental principle in the treatment by condensed and rarefied air was not only rational in theory, but proved itself perfect in practice.

The principal parts of Waldenburg's apparatus are two spirometer-like cylinders of sheet zinc, fitting one into the other, the outer one of which is one metre high and 30 cm. in diameter. The outer cylinder is filled with water up to a mark, as in the spirometer; the cover of the inner cylinder has two openings, one for a manometer, the other for a flexible tube, passing to an orinasa mask. If the inner cylinder, resting upon the bottom of the outer cylinder, with the stopcock closed, is raised and kept in position by weights, suspended from cords passing over pulleys, the air will be rarefied; if the upper and inner cylinder be allowed to receive air at the atmospheric pressure, and the stopcock is then closed, the cylinder being

FIG. 1.

now loaded with weights and made to descend, the air in it will be condensed. According to simple physical laws the degree of condensation or rarefaction remains the same until the cylinder has been filled or emptied, as the case may be, by the lungs.

When the apparatus has been fully charged once it takes—according to the capacity of the lungs—5-30 inhalations to empty it.

From the measure of the inner cylinder the atmospheric pressure produced by certain weights can readily be computed. In using condensed air, Waldenburg generally commences treatment with 20 lbs. weight, = $\frac{1}{3}$ of an atmosphere (which is, of course, an addition to the atmospheric pressure of 15 lbs. to the square inch), advancing by and by to 40 lbs., = $\frac{2}{3}$ atmosphere, seldom as high as 60 lbs., = $\frac{1}{3}$ of the atmospheric pressure.

As I have been informed, Dr. Langman, of this city, procured a Waldenburg's apparatus last year, which he used in the treatment of some of his patients. In regard to the results which he obtained, he read a paper a short time ago before a society of German physicians of this city. Not having the honor of being a member of this society, I did not have the pleasure of hearing this paper. My friend, Mr. John Reynders, exhibited upon this occasion a new pneumatic apparatus, invented by Dr. Biedert, which he had imported at my request, and which I will describe hereafter. I have learned from Mr. Reynders that Dr. Langman's results were very favorable.

When Waldenburg published his first report upon the experiences of his mechanical treatment of pulmonary diseases, he had treated with Hauke's apparatus seven cases of emphysema, one case of phthisis; with his own, seven cases of emphysema, three cases of phthisis, one of which was complicated with catarrh of the upper lobes of the lungs, the other two chlorotic. The emphysematous patients were invariably directed to expire into rarefied air, but whenever an attack of dyspnoea occurred, inhalation of condensed air during the continuance of the attack was ordered. The other patients generally inhaled condensed air.

I will here detail some of Waldenburg's cases:

St., æt. forty-one, suffered during five years of summer asthma; emphysema extensively developed; expansion of the lungs to the free margin of the ribs. July 7, at the pneumotometer, inspiration in maximo, 120 mm.; expiration 90 mm., expiration into rarefied air, one sitting daily, lasting from 10 to 20 minutes.

	Measure of inspiration as indicated by the manometer.	Pressure of expiration.	Vital capacity of lungs.
July 16th.....	130 mm.	100 m.	3,500 ccm.
" 23d.....	150 "	120 "	3,700 "
August 1st.....	150 "	140 "	4,000 "
" 10th....	168 "	160 "	4,200 "

The patient is perfectly healthy, percussion indicating a considerable retraction of the boundaries of the lungs approaching the normal. He goes to St. Maurice, Switzerland, and is making pedestrian excursions without fatigue, whilst formerly ascending stairs was troublesome to him. On the 25th of August, returning, is under treatment again, twice daily, until the 30th of August, with rarefied air for expiration, the pressure being now increased to sixty pounds.

	Measure of inspiration as indicated by the manometer.	Pressure of expiration.	Vital capacity of lungs.
August 25th....	150 mm.	130 m.	3,800 ccm.
" 30th....	180 "	180 "	4,350 "

Thus it seems from this last record that his lungs had expanded somewhat again, probably from sudden removal to the highlands, where the patient also suffered from epistaxis. Under the latter short period of treatment the lungs contracted again to their perfectly normal boundaries, as was proven to be the fact by percussion, and the above figures are (at least as far as pneumatometry is concerned) such as are seldom reached by perfectly healthy and strongly-built persons as maxima. Mr. St. did not only reach the maximum in inspiration and expiration of 180 mm., but could also comfortably maintain the position of the mercury column at a height of 130 mm. in inspiration, and of 125 mm. in expiration. He was not affected with summer asthma this year.

In all the four cases of phthisis an increase of the vital capacity, and of inspiratory and expiratory power of the lungs could be observed; three of them also perceived an alleviation in breathing, sometimes for an hour, sometimes for a longer period, and consequently general improvement was felt. In one of the cases of phthisis the patient had suffered for two years of chronic hæmoptysis, which was treated with the most diverse remedies in vain. Waldenburg had the patient, who was comparatively quite strong, but very dyspnoic, inspire condensed air. The objective and subjective alleviation appeared in a surprising manner. After a few sittings, bloodspitting became less frequent, and afterwards did not take place for three weeks, while during two years the hæmoptysis had scarcely paused longer than eight days. However, in this case a relapse occurred, and although an interruption in the bleeding followed after a few days, it returned again and then persisted as heretofore.

According to the results of Waldenburg, a curative effect against the paralytic conformation of the thorax may be anticipated. In Virchow's *Archiv* for 1873 a case of catarrh in the upper part of the lungs is mentioned, which was treated by Waldenburg with applications of the pneumatic method with perfect success.

The results of experiments in inspiring rarefied air have led to the conclusion that it is the most effectual gymnastic exercise for the thorax, and that, therefore, it is to be recommended as a prophylactic to persons inclined to phthisis.

Furthermore, atelectasis (especially in consequence of pleuritis and paracentesis thoracis), asphyxia, and stenosis of the bronchi are conditions of the lungs which indicate treatment by the new method. Waldenburg, in his summary conclusions, expresses himself as follows:

"Inspiration of condensed air, as well as expiration into rarefied air, increase permanently the vital capacity of the lungs (as shown by spirometry), and the power of inspiration and expiration as measurable by the pneumotometer. This fact appears to me of such paramount importance, that it alone leads me to consider the pneumatic method as one of the most important remedial agents of therapeutics."

Dr. J. Sommerbrodt, of Breslau, published in May, 1874, a series of extraordinary results attained in the treatment of lung disease by Waldenburg's apparatus.

He certainly had opportunity to test well to what extent cures could be effected, having had under treatment by this method during four months more than sixty patients. He found also the limits beyond which no more effect could be produced, in so far that in two cases of very extensive emphysema he could influence the catarrh beneficially, but the emphysema only in a very small degree; and furthermore, in a case of emphysema of ten years' standing he found every attempt fail to reinstate the lost power of expiration. However, in more than fifty cases of emphysema of not so long standing, the most diverse in character and duration, partial recovery never failed to be obtained, and in most cases it was complete.

I cannot abstain from giving some of Sommerbrodt's cases in detail:

Miss H., *et.* 22. Father and a sister deceased of phthisis pulmonum. During her childhood she was not often ill; grew up fast under good conditions of nourishment. During the past three years the patient has become thin and sickly, and has suffered from coughing; menses were generally scanty and irregular. Repeated milk treatment in the country effected no relief. Suffered from almost continual diarrhoea for three months. December 28th, 1873, the patient is weak, thin, bones very prominent, pale mucous membranes, somewhat circumscribed redness on the cheeks, transparent skin. She coughs, has short breath when ascending stairs, not much expectoration, poor appetite. She is 164 cm. high, weighs 115 lbs.; vital capacity 2,000 ccm. (about 600 ccm. below the standard for her height); negative pressure of inspiration, 40-44 mm.; positive pressure of expiration, 40-44 mm. No pathological dulness on percussion anywhere on the thorax. On auscultation in the fossa supra-clavicular. Single sibilant râles, also crackling râles; weak vesicular inspirium and prolonged expirium at the same place. Heart normal. Entero-catarrh. (Tannin 0.66 three times daily.)

After the 29th December inhalations of condensed air ($\frac{1}{5}$ atmosp.) were ordered daily. On the 31st December the patient observed that she could ascend stairs more easily. After Jan. 5, 1874, the inhalations had to be discontinued on account of increased diarrhoea, accompanied with fever, and the patient had to lie in bed. On the 27th January, the intestinal catarrh could be considered as completely cured (by Argent. nitr. *c. op.*). Appearance sickly. Weight of body 108 lbs. On Jan. 28, the evidence of catarrh in the apex of the right lung was indicated by sibilant and crackling râles. Resumption of inhalations of compressed air (2 cyl., $\frac{1}{5}$ atmosp.). After February 2, considerable improvement of color appears. The cough, which often commenced early in the morning and lasted sometimes all day, and the shortness of breath, diminished strikingly. February 7, pressure of inspiration, 90 mm. Expir., 40-44 mm. *No trace of catarrh of the upper part of the lungs apparent.* Loud vesicular inspirium all over the right lung. Digestion good.

After this day the patient inhaled 1 cyl. compressed ($\frac{1}{5}$ atm.), and $\frac{1}{2}$ cyl. rarefied air ($\frac{1}{10}$ atm.) until Feb. 19, by which time coughing had entirely disappeared. Walking and ascending stairs without any dyspnoea; continued increase of the weight of the body. General appearance most healthy.

February 19, negative pressure of inspiration, 40-46 mm. From Feb. 20 to March 20, inhalation of $\frac{1}{2}$ -1 cylinder of rarefied air every alternate day. March 20, weight of body, 120 lbs. March 21, patient was discharged perfectly cured. April 25, vital capacity of lungs, 2,200 ccm.; negative pressure of inspiration, 44

mm.; weight, 120 lbs. No cough. In the upper part of the right lung perfect vesicular breathing; general appearance very healthy. According to last report, patient was doing very well in June, 1875.

Amongst others, Dr. Sommerbrodt treated a boy afflicted with severe chronic bronchial catarrh, which did not yield in the least to any medical treatment. Inhalations of condensed air by Waldenburg's apparatus had the effect of mitigating the attacks of violent coughing. Treatment was commenced March 9, and lasted until the 13th, with continual improvement. After March 15 the patient absolutely did not cough. An equally brilliant result was attained in the case of a singer, generally well known for his beautiful tenor voice. He suffered from chronic catarrh of the trachea and bronchi, and could not sing for four months. Treatment was commenced on March 26, with inhalation of condensed air, and after the twelfth sitting no evidence of disease remained. April 2, the patient sang the tenor's part of the "Creation" with as strong and beautiful a voice as he ever had at his command before the involuntary interruption of four months.

Waldenburg has tried the new method unhesitatingly on many healthy persons and patients, and has arrived at the important discovery, through his researches, that the effects of condensed and rarefied air upon the organs of circulation are equally as exact, constant, and useful for therapeutic purposes as upon the organs of respiration. In respect to this application of the pneumatic method, there are no observations of my own to record. I therefore quote extracts only from Waldenburg's papers.

The blood pressure must be decidedly modified as soon as the air pressure in the lungs is changed by the inspiration of condensed or rarefied air, or by expiration in rarefied or condensed air, as has already been demonstrated by the experiments of J. Müller, Ed. Weber, and Donders. With the assistance of the pneumatic apparatus these effects may be studied in detail.

In inspiration of condensed air the pressure in the lungs, which in normal inspiration is remarkably negative, is notably increased in the use of sufficiently condensed air. The heart and the large vessels are lightened, the more so as the density increases, so that when the air is sufficiently condensed the lungs will cause a pressure upon the circulatory organs enclosed in the thorax. The consequence thereof is an increase of pressure in the arterial system (pulse more tense, even hard), increased flow of blood (pulse fuller), checked flow from the veins into the right heart, increased quantity of blood in the greater circulation, decreased quantity of blood in the lesser circulation. The frequency of pulsation is generally distinctly decreased. Expiration in condensed air of low density has a similar effect upon the circulation as the inspiration of condensed air of high density.

Inspiration of rarefied air has diametrically opposite effects to the inspiration of condensed air. The pressure in the arterial system and the flow of blood are diminished; the pulse loses tension; the entire arterial tube appears smaller; the lessened pressure of air in a very expanded thorax aspires the blood with greater force from the veins into the right heart; the greater circulation is relieved of blood, and the organs enclosed in the thorax, especially the lesser circulation, are abnormally charged with blood. If the air is but slightly rarefied, the pulse will be moderately accelerated.

Expiration into rarefied air acts upon the organs of circulation in a manner similar to inspiration of rarefied air, but in much less degree.

It would be interesting to compare these facts, and

the results of further experiments with the pneumatic apparatus, with the observations made on those laborers who were engaged in laying the foundations of the East River Bridge between New York and Brooklyn, and who were working in caissons, far below the water-level, in an atmosphere of very great density.

Indications for condensed air present themselves in cases for which it is desirable to increase the power of tension of the heart, and accordingly the pressure in the arterial system, to increase the quantity of blood in the greater circulation, and to relieve the lesser circulation of blood, *i.e.*, especially diseases of the heart in which the flow of blood from the lungs or from the left ventricle is checked, as, for instance, stenosis or insufficiency of the mitral and aortic valves, chronic inflammatory processes in the lungs, and bronchial catarrh of severe form.

upon persons afflicted with diseases of the heart it could be shown that by the inhalation of condensed air the systolic elevation of the curve of the pulse was higher, the dirotic curve less marked, and that, on the other hand, after expiration into rarefied air, the systolic elevation is less marked, and the dirotic curve is relatively more marked and higher. This agrees perfectly with Landois's teachings of the condition of the arterial pulse, if the effects produced by the pneumatic apparatus described by Waldenburg are considered. Gradually increasing changes of curves of the pulse in this direction could be proven on patients afflicted with heart disease after continued use of the apparatus thus shown graphically, and also by the disappearance of the other signs of the disturbance of the compensation. In a case of insufficiency and stenosis of the valvula mitralis the curves of the systolic eleva-

FIG. 2.

Indications for rarefied air are presented in cases in which the pressure in the arterial system is to be decreased, the volume of blood in the greater circulation to be diminished, and the quantity of blood in the thoracic organs is to be increased, as in affections of the right heart.

Condensed air is especially *contra-indicated* in cases of abnormalities of the walls of the vessels (atherosis) and disposition to hemorrhage.

By means of the sphygmograph Haemisch demonstrated graphically the effects of the pneumatic apparatus upon the heart and system of vessels described by Waldenburg. As well upon healthy persons as

tion appeared distinctly more prominent under the influence of inhalation of condensed air after fourteen days than before the first inhalation; the dirotism was much less marked; also during the treatment the bronchial catarrh, the cyanosis, and the shortness of breath disappeared, and the quantity of urine increased, and thus the symptoms of the interruption of compensation considerably improved.

Gerhardt recommends for the promotion of the act of expiration in cases of emphysema, instead of expiration into rarefied air, assisting the expiration by pressing the hand on the breast and abdominal walls. In this manner he treated two cases of emphysema

daily two or three times (20-30 respirations), and observed that in both the vital capacity of the lungs increased. Disagreeable consequences in both cases were slight bronchial hemorrhage, and in one, convulsions of the muscles of the face.

Berkart, in London, next to Hauke and Waldenburg, made a contrivance to produce rarefaction of air during the act of expiration. He fits a metal mask with rubber margins to the mouth and nose, from which mask a tube passes to a suction-pump. This pump is worked during every expiration, and indicates the degree of rarefaction of the air on a scale.

Dr. Von Cube has also contrived a pneumatic apparatus which is an improvement on Hauke's invention, and is described and illustrated in the *Berl. klin. Wochenschr.*

Dr. R. Fränkel, of Berlin, in 1874, made an invention in the same direction, which, however, was faulty in different ways, and not of great durability. Later, in the year 1875, he invented a second pneumatic machine, to which I will refer hereafter.

A very superior apparatus was constructed by Dr. Ph. Biedert, assistant surgeon in fourth regiment of Hessian Infantry, in Worms, which I have used myself.

In constructing his apparatus, Biedert availed himself of the principle of the bellows as applied in the accordion, similar to, but independent of, Fränkel's invention. The bellows has the form of a cylinder, 50 cm. in height, 22 cm. in diameter, which is closed at the ends by boards $1\frac{1}{2}$ cm. in thickness, termed covers. Its walls are made of leather, air-tight, and have the necessary strength to maintain their ordinary form against over-pressure of air. The lower cover has a perforation near its front margin into which a rubber tube is fitted air-tight, and when in use is prevented from collapsing by a spiral wire which it contains. Straps are fastened crosswise to the upper cover for holding weights; pins being inserted which fit into holes in the weights and prevent their slipping. These weights are round plates of iron of the diameter of the covers of the bellows; two are $2\frac{1}{2}$ lbs. each, the others 5 lbs. each; 30 lbs. go with every apparatus. When the bellows is expanded as much as possible it contains a column of air, the diameter of which is upon an average 2 cm. less than that of the covers, on account of the zigzag outline of the walls of the bellows. The pressure which the covers of the bellows must support is equal to that upon a circular plane 20 cm. in diameter, or 314 square cm. of area, which will be 648 lbs., taking 1,033 grammes as the pressure upon a square cm. If the bellows is charged with 1 lb., the condensation of the air will be $\frac{1}{648}$; with 10 lbs. it will be $\frac{1}{64.8}$; with 20, $\frac{1}{32.4}$; with 30, $\frac{1}{21.6}$. If the bellows is reversed, weights downward, and in this manner expanded, the cubic contents will be equal to the area of the cover multiplied by the height of the expanded bellows, $314 \times 50 = 15,700$ cm.

The other part of the apparatus is a stand of iron consisting of four opposite iron bars, two thinner and two stronger, connected on top by a flat ring, the diameter of which is 24 cm. The lower ends of the bars are fastened to the lower cover of the bellows, which can readily be removed. The upper cover of the bellows can be moved up and down, and is kept in line by guides running on the two upright thin bars of the stand. Guides are also attached to the body of the bellows, which slide on the two stronger upright bars. Small projecting pins are attached to the centres of the larger bars, upon which the whole apparatus swings. These pinions are supported upon uprights from a firm base of wood. Upon the pinions the apparatus can be

turned by two handles, one of which projects from the ring above, the other at the lower end from one of the bars. This permits of a half turn of the apparatus backward.

The machine is placed upright on the margin of a table, so that the tube will lie in a groove cut into the wooden base, and the desired quantity of weights is fastened to the upper cover of the bellows. If the upper end is turned down, the weights will sink and the bellows will fill itself with air. The bellows is then turned back, while the patient compresses the rubber tube with his fingers until he is ready to inhale through the mouth-piece attached; he then gradually inhales the air as the weights compress the bellows. While the patient expires into the free air the bellows is filled again by turning, and the operation continued in this manner *ad infinitum*. For expiration into rarefied air the tube is compressed and the bellows turned weights downward; applying the tube to the mouth the air passes from the lungs into the partial vacuum produced by the expansion of the bellows. The bellows filled with the expiratory air is emptied by turning, while the patient inspires air at the atmospheric pressure, and the operation repeated.

Finally, the patient can inhale condensed air from the partially filled bellows, and after turning the apparatus exhale directly into rarefied air.

The first patient on whom I used it was Fred. Staubach, *et.* 60 years, tailor. Called at my office for the first time May 28th, 1875. He had suffered during ten years from asthma, and was troubled very much in the morning, when rising, with a violent cough. Emphysema of lungs very extensive; lower boundaries of the lungs as far down as the free margin of the ribs; no dulness over the heart on percussion; coarse râles on the right side; exaggerated respiration. Patient suffered besides from chronic catarrh of the intestines, and had for a week violent diarrhœa. Ordered a solution of ferrum oxydatum dialysatum, and after a few days all symptoms of the intestinal catarrh disappeared, and did not return until the present time (July 3d). I commenced the pneumatic treatment on June 16 only, as I had some improvements made on the apparatus, consisting mainly in a stronger bottom made of three layers of wood arranged cross-grained—the original bottom having given way and leaking. The patient came from a distance, and on account of excessive weakness was accompanied by his wife. I made him exhale into rarefied air, the apparatus being weighted with $12\frac{1}{2}$ pounds. After ten minutes the patient, an old man, was fatigued, and returned home.

June 17th. Had felt very easy on his homeward journey after the previous visit, and used the apparatus this time without my assistance for fifteen minutes.

June 18th. Did not come on account of bad weather.

June 19th-24th. Daily use of apparatus, weights as before ($12\frac{1}{2}$ pounds), generally for twenty minutes at one sitting. He now came all alone during the hot weather, and in the afternoon between two or three o'clock. He was highly gratified with his improved condition, while for many years exercise such as ascending stairs caused him great fatigue, obliging him to take a good rest on each floor as he went up. He can now, without inconvenience and without resting, ascend to the third floor.

June 25th. No sitting.

June 26th-27th. Continued use of apparatus. During the past week he coughed only once in the morning. Apparatus charged with $17\frac{1}{2}$ pounds.

June 28-29th. Weight 20 pounds.

June 30th. Weight $22\frac{1}{2}$ pounds. During the past eight days no cough.

July 3d. Weight 25 pounds.

Patient has left the city on a visit of some length to his children, living in the country. The general improvement in this case is so evident that it is noticed with surprise by all the man's acquaintances who meet him. It is interesting to note that, having certainly no knowledge of anatomy or physiology, he should have observed that while expiring into rarefied air he had a sensation as if something was being drawn up from the abdomen into the chest. Waldenburg's patients perceived the same, and thus described the elevation of the diaphragm.

Another case in which I have been operating with Biedert's apparatus is M. Eck, 33 years old. Married. Tobacco dealer. Parents died when they were about fifty years old. His father had asthma, while his mother suffered a great deal from pulmonary hemorrhage, and finally died from phthisis pulmonum. A sister is also afflicted with asthma. Patient lost the sight of the left eye in consequence of some illness during infancy. His health was always delicate. At the age of twenty he suffered considerably from bronchitis. The year following he was sick with typhus fever, which lasted fourteen weeks, and sick again with remittent fever for six weeks, when twenty-six years old. During the last year the patient has suffered from cough and expectoration: coming to my office for the first time in September, 1874, had fever and night sweats. On examination chronic catarrh of the apex of the right lung was found. Treatment consisted principally of tonics. No narcotics. The patient being in straitened circumstances a journey South was out of question. Taken as a whole, the condition of the patient did not improve much, although he visited me at regular intervals and took religiously his iron, chinin, and the unavoidable cod-liver oil.

Examination on July 1st, 1875, revealed relative dullness on percussion at the right apex, posteriorly as far down as the middle of the scapula, and anteriorly as far as the first intercostal space. Over the same space *sibilant râles* were heard on auscultation. Expiration is prolonged. Height, 5 feet 8 inches; weight, 113 lbs.

Treatment by pneumatic method (inhalation of condensed air) was commenced on July 6th, 1875. At this time there existed severe cough, accompanied by reddish-colored sputa—especially is this the case in the morning; sometimes shortness of breath. *Taking a deep breath always excites the cough.*

At the commencement of treatment Biedert's apparatus was charged with 7½ lbs. This weight was increased every day by 2½ lbs. until July 11th. From this day until July 22d we operated with the weight of 20 lbs., increased again to 22½ lbs. on July 23d, with which we are operating yet (July 31st). Duration of daily sitting, twenty minutes.

July 9th, there was a remarkable increase of reddish-colored expectoration, together with a tablespoonful of blood; sputa were reddish colored also during the day until July 12th. July 19th, I prescribed an infusum scellis cornuti.

July 13th to 18th, cough easier, expectoration less, sputa still show traces of blood, being reddish colored; but this color of the expectorated matter, and all traces of blood in it, have altogether disappeared since July 18th. From this time until to-day (July 31st), the amount of sputa is on the average only half as much as it was at the commencement of treatment; some days it is hardly a quarter the former amount.

During the week ending July 31st the patient is doing remarkably well, and finds himself in the best of spirits. Examination made to-day, July 31st, shows

that the percussion sound over the space above mentioned is higher and shorter, inspirium vesicular everywhere, expirium prolonged; *to-day I can discover no râles*. The patient calls my especial attention to the fact that he is able to breathe very deeply without exciting the cough by it, as such used to be the case formerly at the slightest exertion of this kind.

The pneumatic method has been modified by Dr. von Cube, of Mentone, and Domanski, of Krakau, Poland, in applying medicines to the deeper air-vessels by means of condensed air (which could not be approached by any local therapeutics, not even by inhalation). They recommend this local treatment, for instance, in cases of phthisis pulmonum in the later stage, when the bronchial secretion is more copious and the inner surface of the lung resembles an ulcer such as no surgeon would treat indifferently. To check the pathological changes, and to diminish the bronchial effusions, medicines, especially when they are given through the stomach, may not suffice, which may be readily appreciated when it is remembered that surgeons mostly treat wounds and ulcers locally; not, however, dispensing altogether with general treatment. For introducing medicines in this manner into the lungs, Domanski causes the condensed air leaving the apparatus to pass through a vessel in which the medicated vapor for inhalation is produced.

For this purpose he removes from Waldenburg's apparatus the mask and stopcock, fills the inner cylinder as stated with atmospheric air, and without taking the weights from the hooks, connects the rubber tube with a glass tube, reaching almost to the bottom of a Woulff's bottle. In this bottle, for enlarging the volatilizing surface, there is some cotton impregnated with the volatile medicine. In the second neck there is a short glass tube, which, by means of a rubber tube, is connected with the mask and stopcock. Everything is, of course, air-tight. If the weights are now removed from the hooks and laid in any quantity on the inner cylinder, all air contained in the apparatus will be compressed to an exactly known degree, and if the stopcock at the mask is now opened, the air will pass from the cylinder into the Woulff's bottle, where, impregnated with medicated vapor, it enters the lungs. After the inhalation is completed, the stopcock is closed, and the patient expires into the open air, and then repeats the operation. The medicines used up to the present time are oleum terebinthinæ, oleum pini, creosot., and acidum carbolicum. Von Cube, as well as Domanski, have treated a number of patients and obtained good results. The histories of these cases, however, are not yet ready for publication.

I have endeavored to describe the pneumatic method in its historical development, and now I will dwell more particularly upon some modifications of the use of condensed air, originating with v. Cube.

In cases in which he desires to produce an effect upon one lung only, the patient inhales half inclined upon one side, with a hard cushion placed under the loin. The air entering the lung in this posture overcomes the resistance of that part of the thorax more readily which does not sustain the weight of the body. Among others, Dr. v. Cube treated a patient who had had, several months previously, a pleuritis exsudat. on the left side, with what result has not yet been made known.

Besides the apparatus described, a number of others have been devised by Högges, Finkner, Treutler, Stoerk, and others. The literature of these apparatus is not at my command, certainly none of these have come into general use.

The non plus ultra of simplicity and cheapness is

the new contrivance of B. Fränkel, of Berlin, referred to above, resembling the ordinary accordion. The annexed illustration shows the apparatus as used. As may be seen, it consists of the bellows of an accordion.

FIG. 3.

On one side a metal tube is inserted 2 cm. in diameter, which carries the mouth-piece; the latter may consist of an inflating rubber cushion, similar to a pessary. Fränkel recommends the sitting position for using the apparatus. If the bellows is expanded by drawing the accordion apart, the air contained in it will be rarefied; if it is compressed, the air is condensed. If the patient, during the expansion or compression, applies his mouth to the cushion the effect of the rarefaction or condensation of the air will communicate itself to the intra-thoracic air. The apparatus is without valves; as it is very easy to apply or withdraw the mouth from the cushion at the right moment, any such arrangement as valves is therefore not necessary. If expiration is to be made into rarefied air, the mouth should be applied to the cushion and the bellows expanded. After the expiration the mouth is withdrawn from the cushion, and while inhaling the free air the patient closes the bellows, for expiring, the apparatus is found empty and ready.

All varieties of effects described with Biedert's apparatus can also be produced with Fränkel's apparatus, by the patient himself, without assistance. He can either inspire condensed air only, or he can inspire condensed air, and expire into rarefied air.

On the margin of the apparatus there is a centrimetrical measure, which plainly indicates by how many centimetres the wooden disks are separated or brought together. This shows the volume of air which has been drawn into or expelled from the apparatus. The apparatus is 35 cm. in height, and 16 in breadth. If the foldings are considered, the bottom area will be $15 \times 34 = 510$ square cm. The expansion of the apparatus of one cm., according to the measure affixed, would correspond with 510 cm. of volume.

Fränkel considers the attachment of the dynamometer to his apparatus as unnecessary.

The air from this apparatus is more completely and more fully perceived by the lungs, and with less modification of its original pressure than by any previous invention, due to the shortness of the breathing tube. All excess of action is avoided, as it is worked by manual force only. Fränkel having found that

with his greatest efforts he could not condense the air above $\frac{1}{20}$ of an atmosphere, nor the power of suction above $\frac{1}{20}$ atmosphere.

The patient is sensitive to the amount of pressure and draught upon his lungs, and can regulate both according to his own feelings. Fränkel leaves this regulation to the patient, but warns him against over-exertion.

The advantages of the apparatus are, that it is easily transportable and applicable anywhere (for inducing artificial respiration in cases of chloroform asphyxia, asphyxia of the new-born, poisoning by oxide of carbon, etc.). The apparatus is so cheap that poorer patients can avail themselves of it and use it at home.

According to my judgment, Biedert's apparatus will be used more especially in physicians' offices, and Fränkel's by the patients themselves at their residences.

Résumé:

1. The pneumatic method answers the indication for a more thorough ventilation of the lungs, and an increase of their capacity and power of breathing.

2. The condensation of air, and especially rarefaction of air, have not only a symptomatic effect, but also a decidedly curative one, especially in cases of emphysema.

3. By no method—with exception of Gerhardt's impracticable one—can be accomplished the reduction of the abnormally expanded lungs to the normal or even a smaller volume, or can be caused a retraction of the emphysematous lung.

4. Methodical expiration into rarefied air is the only remedy for emphysema, and its application is highly commendable.

5. The pneumatic method is a powerful means of affecting mechanically the action of the heart, and the circulation of the blood.

6. Hardly any other therapeutic remedy, perhaps with the only exception of cold, is equal to the pneumatic method in certainty of effect, which can be mathematically expressed, like the physical law itself on which it is based.

ELASTIC LIGATURE FOR SECURING THE FUNIS.

By GEORGE BAYLES, M.D.,

NEW YORK CITY.

DR. PULLING's article in THE MEDICAL RECORD of July 17th, describing his device of an elastic clamp for securing the funis after parturition, attracted my attention, especially as by it I was reminded that it might be of service to describe a more simple and ready, yet equally efficient, method that I have adopted for the same purpose.

I carry in my pocket-book a moderate supply of small elastic india-rubber rings, of a size that would be somewhat stretched by being drawn over the first point of the fourth finger of my hand. By so carrying these rings I have them always with me, and need not resort to the clumsy and never perfectly certain method of tying with such string as may be provided by the attendants of the patient. When ready to apply the rubber ring I double the umbilical cord upon itself, so that three inches are taken up in the loop (or four inches if the cord should be exceptionally thick), as close to the umbilicus as possible. I then spring a rubber ring over the loop and roll it down to within half an inch of the abdominal surface. I then cut the funis about half an inch from the rubber ring, external to the loop. I have therefore

two portions of the funis constricted by one rubber ring. When any doubt occurs as to the sufficient constricting force of the ring, I double the ring upon itself and stretch it over so that it shall do duty as a double strand. Another ring is commonly slipped over the placental end of the funis. This method of ligation has proved in my practice entirely reliable, and for cheapness and convenience is all that can be desired. There is no slipping, and even should the end slip the ring, the stump is still engaged at the base, and quite secure.

It compresses equally firmly after exudation has diminished the fulness of the cord. It determines the exact line of separation, and completes the sloughing process with greater promptness than by the usual method of tying merely the extremity of the umbilical stump. The loop does not form an uncomfortable bunch, for it soon flattens out parallel with the surface of the abdomen, under the pressure of the binder used in infantile dressing. The raw surface of the cut end of an umbilical stump thus ligated, and dressed by the linen wrap as usual, will not moisten and excoriate the tegumentary surface of the abdomen more than by any other method. It is in practice a perfect ligature, which has never caused me the slightest anxiety, as it has not failed to prevent hemorrhage in all the cases (now more than a hundred) in which I have employed this common rubber ring, to be found in the stock of any stationer.

37 WEST 43TH STREET, July 29, 1875.

A CASE OF MEDIAN LITHOTOMY.

By GEORGE R. FOWLER, M.D.,

BROOKLYN, N. Y.

I REPORT this case of median lithotomy because I think the attention of the profession ought to be called to the advantages which this method of operating possesses over all other cutting operations for the removal of vesical calculus; and that any case operated upon should be reported in order to support the truth of the conclusions of Drs. Sands and Little, of New York, who have striven more than any others in this country to popularize this, the modification of the Allarton operation.

G. G., aged twenty, had been complaining since he was four years of age of symptoms of vesical irritation, being subject to frequent attacks of dysuria. These would pass off after a few days' duration, he being troubled with shooting pains in the penis, extending to the glans and prepuce.

Suspicion of stone had been entertained, and upon several occasions he had been sounded by different physicians, but no calculus had been discovered.

When first called, I found him pacing the room in dreadful agony, holding the penis strongly grasped in a napkin, the urine dribbling away upon the latter every few minutes.

No hæmaturia had occurred, but the symptoms were so strongly marked that I at once declared my belief that he was suffering from a vesical calculus.

The patient, almost crazed with pain, at first utterly refused to allow a sound to be passed, but finally yielded, and the calculus was discovered. The sensation was conveyed of a large stone, although its dimensions were not accurately determined by the lithotrite.

On December 15, 1873, I performed the median operation of lithotomy, Drs. Krackowizer, Kammerer, Barber, Pilcher, Hamilton, and Maddren, being present.

The patient, being under ether, a staff having a broad and shallow groove on its posterior surface, was passed into the bladder, and entrusted to the firm and steady grasp of Dr. Krackowizer. The index finger of the left hand was introduced into the rectum, its palmar surface upward, and its extremity resting in the groove of the staff at the anterior portion of the prostatic body, at its junction with the membranous portion of the urethra. A long and narrow-bladed knife was then introduced, with its back downward, about half an inch from the anterior verge of the anal orifice, and, with my finger acting as guide, the point entered the urethra at the junction of the membranous and prostatic portions. The knife was then carried upward until the whole length of the membranous portion of the urethra was divided, about half an inch. The knife was then withdrawn, at the same time enlarging the external incision.

The left index finger was then introduced into the wound, and by firm pressure and a steady boring motion the prostatic portion of the urethra was easily dilated. The staff was then withdrawn, and the forceps passed alongside of the finger, Dr. Pilcher making firm pressure over the suprapubic region in order to bring the stone easily within reach.

The calculus having been grasped with its longest diameter parallel with the long axis of the blades of the forceps, it was found to be too large to allow of extraction without running the risk of producing a dangerous amount of laceration of the neck of the bladder. It was therefore crushed by the forceps and withdrawn piecemeal.

The hemorrhage was very insignificant, and the patient rallied well from the shock.

By the third day the patient had complete control of the urine, passing it through the wound and retaining it at will.

On the sixth day he passed urine per urethra, and on the fifteenth day per vias naturalis entirely.

Upon examining the stone there was discovered a hair embedded in its encrusting portion. It had evidently been carried ahead of a sound down the urethra upon some previous occasion while he was being sounded. This suggests the possibility of producing a calculus by want of attention to this point. Every surgeon must recall instances where, previous to passing a catheter, he had found and removed a hair from the pubic region, lying across the meatus.

Dr. Charles Jewett kindly made the examination of the calculus for me, and made the following report: "Weight of calculus, 420 grains; the nucleus is uric acid. The body of the stone, about half its weight, is oxalate of calcium. The encrusting portion is a mixture of phosphate of calcium and triple phosphates, the material of the so-called fusible calculus."

EXTRA FEES.—With a view to encourage patients and others, who may be in need of the attendance of a physician, to send him word at such time as will admit of his arranging his work for the day, the Forfarshire (Scot.) Medical Association have confirmed the resolution unanimously adopted at last year's meeting, "that all visits sent for at 10 A.M., and requiring to be attended to the same day, should be charged at an extra rate."

PUNISHMENT FOR CARELESSNESS.—A butcher, living at Linden, near Hanover, has been condemned to two years' imprisonment for gross negligence in selling a quantity of trichinized meat, which caused the illness of about four hundred persons, and the death of more than fifty.

New York, August 28, 1875.

PRELIMINARY EDUCATION AND INDEPENDENT EXAMINING BOARDS.

Our esteemed British contemporary, the *Medical Press and Circular*, in commenting upon our remarks regarding the necessity of proper preliminary education for medical students, gives a very encouraging account of the utility of enforcing such a provision by the experiences of medical education in Great Britain. The system of preliminary education which is there enforced, as well as in the other European countries, carries its recommendation upon its face, and needs no argument to prove its indispensability. The institution of independent examining boards is another feature in their system of medical education which proves the benefit of taking from the various medical colleges the absolute right to confer degrees.

These reforms, which have made medical education what it is in that country, have been the gradual outgrowth of much discussion, much up-hill work, and a great deal of hard fighting against the selfish interests of the different medical schools. The profession in America has the same task before it, if it would accomplish so desirable a result, and the more the subject is agitated, the more thoroughly it is discussed, the more independently it is advocated, the sooner will the necessary changes be made. The individual interests of the colleges here are not a bit stronger than they were in the mother country when the question was first brought up for the candid consideration of the progressive educators of the profession there. It is true we have to contend with many difficulties in securing a uniform law upon the subject, difficulties which are always inherent to a Republican form of government, but these are not by any means insurmountable when the justice of the principle is fairly vindicated, and the necessity of the reform fairly proven.

In respect to independent examinations the medical profession is very much behind the others, for example

the clerical and the legal. The latter, more especially, have considered an impartial and independent examination for admission to the bar one of the prime requisites to insure the fitness of every attorney for the practice of his chosen calling. The board of legal examiners are regularly appointed by law, and their decisions upon the qualifications are considered final and absolute.

It is true that within the past few years there has been an exception to the rule in favor of the Columbia College and University Law Schools, which by virtue of special legislation have been empowered to grant the requisite licenses independent of the bar committee. But this privilege is now very seriously questioned by leading legal educators, as calculated to subvert the best interests of the profession and lower the necessary standard of qualifications. With an implied intention of offering greater facilities for the study of law, these schools have taken a step backward, which places them on a par with the majority of our medical colleges.

A leading newspaper, in commenting upon the necessity of a reform in this matter, makes the following remarks, which, find an exact picture in the condition of our own schools, and equal necessity for the desired reform:—

“It is certainly matter for regret, if not for some disappointment, that the colleges of law in New York have not, in the judgment of the Courts, justified the legislative partiality which permitted them to bestow upon students, after a preparation comparatively brief, the degree of Bachelor of Laws, and authorize them to practise law. But opinion continues to gain ground that these privileges have not been put to the best use in this State. The degree has come to be altogether too common, and, unhappily, little if any distinction now attaches to it. In this city a mob of young men is annually thrust into the most arduous of professions, when their minds are immature, and altogether undisciplined by any previous contact or proper acquaintance with the life and duties of the practical lawyer; and it will hardly be denied that many who are unequal to a manly effort to meet the requirements of the Courts, join classes in the schools in hope, if not with the expectation, that they will thus find an easier way to the bar.”

The evil although of comparatively short duration, has aroused the attention of the Supreme Court of New York, which is keenly alive to the necessities of the occasion. In keeping with this sentiment to raise the standard of legal qualification, Mr. Justice Leonard offered a resolution, which was unanimously adopted at the late Convention of Judges at Albany, requesting the Legislature to amend the existing statutes so as to allow law schools only an equal period for the time spent in attendance at them, upon the terms of clerkship prescribed for other students by the Court of Appeals; and requires, besides, that graduates of schools, before they can apply for admission to the bar, shall be examined in the same manner as other applicants.

This contemplates the same change which we have considered so necessary in reforming our present sys-

tem of medical education, viz., that our schools shall offer all the necessary facilities for a first-class education, but that the special privileges of granting a license to practise shall belong to an independent examining board. There seems to be a fair promise that this change for the better will be made in the study of the law; at all events the proper initiative seems to have been taken.

In the clerical profession the system of independent examinations has been carried out with good effect, and in spite of the privileges which the seminaries have of granting degrees, the various clerical boards are practically responsible for the fitness of the candidate. In almost all denominations, before the candidate is fairly admitted to orders, and takes his charge, he appears before a committee of clergymen, who take every pains to discover his fitness for the discharge of his future responsible offices. The opposition to the lay ministry, which of late years has been so decided and so widespread among the different denominations, had the best part of its foundation in a determination to preserve the intellectual power and the educational qualifications of the regular clerical profession. When we compare ourselves with the other liberal callings, and witness the jealous zeal which characterizes their determination to keep their standard of education up to the highest possible requirements of the age, we have need to feel ashamed of the apathy in our own ranks, at the indifference to the monopoly on the part of medical schools of all our educational interests, and at the quiet submission to all those demands which we know to be actuated by the smallest of motives and the most selfish of purposes.

We believe that the foundation of all reform in medical education rests mainly upon the enforcement of the two conditions, the necessity of which we have so frequently pointed out, viz., a proper preliminary education and an independent examining board. These two points are the *alpha* and *omega* of the requirements of the prospective practitioner, while the office of the medical college is merely to fill up the gap between the two. The opposition to these reasonable propositions comes very naturally from the colleges themselves, whose interest it seems to be to gain a reputation for large numbers of matriculants and a large graduating class. It is in the hope, however, that the time will eventually come when these propagating schools will care more for the quality than the quantity of the material which they may control, that we shall continue to agitate the utility of the reforms proposed.

SWIMMING EXTRAORDINARY.—Captain Webb, said to be the son of a medical man, lately swam from London to Gravesend, a distance of twenty miles, without any artificial aid whatever. It is said that he proposed this month to swim from Dover to Calais, an undertaking which, if successful, would eclipse Paul Boyton's feat by considerable, and would probably be one of the most severe taxes of human stamina and endurance that has yet been recorded.

Reviews and Notices of Books.

CHOLERA: HOW TO PREVENT AND RESIST IT. By DR. MAX VON PETTENKOFER, Professor of Hygiene, University of Munich, Obermedicinalrath, President of the Sanitary Commission of the German Empire, etc. From the German. Translated (with Introduction and Appendix on the International Cholera Conference of Vienna) by THOMAS WHITESIDE HIME, A. B., M. B., etc.; Ex-royal Scholar Trin. Coll. Dub.; Lecturer on Obstetric Medicine and Diseases of Women and Children in the School of Medicine, Sheffield; Medical Officer to the Hospital for Women; Surgeon-Accoucheur to the Public Hospital and Dispensary; Fellow of the Obstetrical Society, London, etc. Revised by DR. VON PETTENKOFER. With Illustrations and a Chart. London: BAILLIÈRE, TINDALL & COX. Paris: BAILLIÈRE. Madrid: C. BAILLY-BAILLIÈRE. 1875.

This small volume presents to the reader the advantage over the German work of Pettenkofer that it contains a short article from Dr. Hime, as well as the conclusions arrived at by the Vienna Conference of July, 1874. It may be considered as a summary of the most recent reliable views with regard to cholera. Although some points concerning the characteristics of the disease and its treatment, which were considered as settled, still remain *sub judice*, yet our knowledge in this direction has advanced. The knowledge gained is also such as can be made of practical value in averting or diminishing the dangers of an epidemic.

How far the ground-water influences the existence or spread of cholera is as yet undecided. Pettenkofer states that "as in certain places the existence of typhoid fever exhibits a certain temporal dependence on the variations of the moisture of the soil, of the so-called 'ground-water,' in like manner it is probable that cholera is similarly dependent, though, owing to the fortunately less frequent prevalence of cholera, the relationship cannot be so regularly and satisfactorily proved as in the case of typhoid fever." One or more of the elements which favor *germination* seem to have long ago been regarded as connected with the spread of cholera, although the evolution of the idea belongs to later days. Mr. Barnes, surgeon in the Hon. East India Company's service, who had charge of the district of Jessore, in Bengal, from 1810 till 1822, wrote that "if the rain did not terminate till the end of September, and the floods subsided gradually during the month of October, the autumn season was free from extensive sickness; but if the rains broke up at the end of August, and the waters sank rapidly during September, the disease commenced its attack among the natives at the beginning of October, carrying death and desolation in its progress until about the middle of December, when the complaint became checked, and in a short time apparently extinct." The gradual fall of the waters might be regarded as unfavorable to germination by maintaining an excess of moisture in the soil, but the rapid sinking of them would leave a damp soil most favorable, under a burning sun, to vegetable life. "The extremes of drought and wet," writes Dr. Hime, "are alike unfavorable to the development of the cholera germ."

In the Introduction a tribute is paid to the extraordinary energy and skill with which Prof. von Pettenkofer has investigated this disease. Here also an explanation is afforded of the ground-water theory, and several experiments are given illustrative of the permeability of the earth to air and water. As is stated:

"Nothing can be more erroneous than the common idea that the atmosphere ends where the ground begins. The ground (using the term in its general acceptation) is not half so solid as it seems, and currents of gas and water circulate freely through almost any part of it except the most compact clay and rock."

From this is deduced the necessity of maintaining the soil as free from sewage pollution as may be, since air defiled by such impurities circulates freely through the ground, or rises as a poison into the superjacent atmosphere. At the same time, a filthy soil offers a favorable development to the germs of a pestilence.

As the Introduction to this volume is interesting, so is the Appendix, which consists of the conclusions arrived at by the International Sanitary Conference, which was held in Vienna, July, 1874.

The conclusions referring to the various features of cholera were adopted by vote, and are the expressions of opinion from deputies who represented twenty-one governments of the Old and New World. As might have been anticipated, while some points were unanimously adopted, with regard to others there was a well-marked difference of opinion. It may be said, nevertheless, that the sentiments were sufficiently in accord to indicate progress towards a gratifying unity of opinion concerning the nature and prevention of this scourge, which has been at once both a pestilence and a puzzle.

A TREATISE ON CUTANEOUS MEDICINE AND DISEASES OF THE SKIN. By H. S. PURDON. London: Baillière, Tindall & Cox. 1875.

THIS work is composed of fugitive essays and lectures delivered by its author in the Belfast General Hospital. Its contents include a wide range, and in the twenty-three chapters very many affections of the skin are brought into notice. It is quite difficult to determine the exact worth of the book, as it contains almost nothing not known to persons well read in skin diseases, while the want of system in it is a drawback with the general reader. The manner of construction of the whole book, it must be confessed, is bad, and contributions like this, which are, we are sorry to say, too frequently put forward of late, should be treated according to their merits. It is evident by reading this book that the author is zealous in his love of the study of skin affections, yet it is clearly seen that his views are not accurate, and that he is given to careless or rather superficial thinking. He evidently reads copiously, but, judging from his writings, he does not clearly master what he reads: the result is that in this work we have a vast amount of erudite knowledge derived from others, which is not well assimilated in his articles, so that in each chapter there is a painful lack of coherence in describing a subject, by which the author's own views are not well brought out, nor are those of others shown up by comparison. Then, again, in matters of theory there are evidences that the author does not clearly comprehend certain views, as we meet further on contradictions which would not have occurred had the idea been mastered. Indeed, the present is a bad specimen of book-making. The style is not clear, nor is the grammar faultless. The diseases described have already been treated of very well by other authors, and their reconsideration by Dr. Purdon is productive of no good. The plain fact which strikes a person who reads the book attentively is, that the author is a superficial observer, a loose thinker, and a man who has not the power to write a logical, terse article. In the present instance he evidently imagines that he is saying something of importance, but the difficulty with the reader will be to determine what he has said.

Progress of Medical Science.

ON THE TREATMENT OF UTERINE FIBROIDS BY ERGOT.—*The Medical Examiner* for July 1st contains two articles of considerable interest, with reference to Hildebrandt's method of treating fibroids of the uterus with ergot. One of these articles consists of an abstract of a paper, read before the American Medical Association, at Louisville, last May, by Dr. W. H. Byford. In this paper Byford discussed the ergot treatment on the basis of an analysis of 103 cases, collected by him, where this treatment had been pursued. His statistics are exceedingly favorable to the method of treatment under consideration, as appears from the following results: Twenty-three cases out of the whole number are reported cured; in thirty-eight more the tumors were diminished in size, and the hemorrhage and other disagreeable symptoms removed; nineteen of the remainder were benefited in that the hemorrhages and leucorrhœal discharges were relieved, while the size of the tumors remained unchanged. Only twenty-one out of the whole number of cases resisted the treatment entirely. Consequently the result of the treatment in eighty out of the one hundred and three cases was decidedly beneficial.

The ergot was administered both hypodermically and by the stomach, and in some instances injections were made into the cervix uteri or into the substance of the tumor itself. The objection to the internal use of the drug is the gastric irritability which is apt to be developed, whilst the hypodermic injections are liable to produce inflammation and suppuration. The frequency of these ill effects depends, to a certain extent, upon the form in which the ergot is used. Squibb's solid extract is recommended by the writer, both for subcutaneous injection and for administration by the stomach. This preparation is very similar to Wernich's formula, which is used by Hildebrandt. For hypodermic injections it is reduced with water, in the manner described by Squibb, so that each minim of the solution represents four grains of ergot in powder. From ten to twenty minims of this solution are injected once a day, or once in two days. If used internally, the solid extract is recommended to be given in pills, coated with gelatine. A pill of five grains is equivalent to thirty grains of crude ergot, and is administered two or three times a day. Painful contractions of the uterus are generally produced shortly after the administration of the ergot, and last for ten or twelve hours. Sometimes, however, the good effects of the drug are experienced without these painful symptoms being developed. The latter may also be somewhat alleviated, it is claimed, by means of the hydrate of chloral, which appears not to interfere with the remedial action of the ergot.

It is observed that the action of the drug upon fibrous tumors of the uterus may be evinced in three different ways: (1.) A gradual disintegration and resorption may be produced; (2.) the nutrition of the tumor may be so suddenly interrupted as to cause rapid disintegration and decomposition, followed by the discharge of the putrid contents, and (3.) finally the tumor may be partially or totally expelled from the cavity of the uterus without undergoing other change, the uterus being more or less inverted. Its removal can then readily be completed by a surgical operation.

In the same number of *The Medical Examiner* Dr. E. P. Allen reports a case of uterine fibroid treated by Hildebrandt's method, in which, on two occasions, the

subcutaneous injections of ergot were followed by severe attacks of phlebitis. The tumor was of very large size, extending three and a half inches above the umbilicus, and was attended with profuse menstruation. At first the ergot was administered hypodermically in the form of Squibb's fluid extract. Fifteen minims in an equal quantity of water were injected in the region of the umbilicus, and the dose was soon increased to twenty drops. The injections caused considerable pain, with some redness and tumefaction. The effect, however, during the first few weeks was decidedly favorable. The menses ceased to be profuse, and their duration was diminished, while the circumference of the abdomen, at its most prominent part, was reduced from thirty-six to thirty-two inches. Thirty injections had been given, when severe pain in the left side and hip, together with marked febrile symptoms, interrupted the treatment. The pain and fever increased, and an inflammatory process gradually involved the whole of the left leg. The process differed in no respect from an ordinary case of phlegmasia dolens, and lasted for some three weeks.

Three months after the ergot was stopped the menses had again become profuse, and the tumor had greatly increased in size. The fluid extract of ergot was then given by the mouth for some time, with the effect of arresting the hemorrhage and of checking the growth of the tumor. But finally the stomach became too irritable to tolerate the medicine, and the patient was obliged to discontinue it. The ergot was not resumed for a number of months, but the tumor continuing to enlarge, and the symptoms becoming very distressing, the patient was at length induced to have recourse again to the subcutaneous injections. This time Squibb's solid extract was used, in a watery solution, which appeared to cause less irritation than the fluid extract. The injections were made near the umbilicus, as at first, but more on the right side. The strength of the solution injected was such that one drop represented a grain of ergot. The injections were used for eight weeks, with the same good effect as in the first instance, though the relief was produced somewhat less rapidly. On increasing the strength of the solution so much irritation was caused as to produce an abscess. This having healed the injections were continued (of the same strength as the first) on the right side, until symptoms again occurred of a commencing phlebitis. The veins became enlarged and painful, and the inflammation proceeded rapidly downward, and culminated in an attack on the right side, precisely similar to the previous one on the left. After recovering from this attack the hypodermic injections were continued for a short time in the arm without ill effect. As to the immediate cause of the attacks of phlebitis no positive opinion is expressed.

THERAPEUTIC OBSERVATIONS ON THE ACTION OF ESERINE IN CHOREA.—M. Bouchut has undertaken a series of investigations with regard to the action of eserine—the alkaloid of Calabar bean. His conclusions are summed up as follows:—When eserine is administered to children, in moderate doses, it causes a diminution of muscular contractility, though the contractility of the small blood-vessels is increased.

Eserine, or its sulphate, may be administered either hypodermically or by the mouth; in the latter case it should be given on an empty stomach.

In the form of subcutaneous injections eserine, or its sulphate, may be given in doses of from three to five milligrammes, beyond which it is not regarded as safe to go.

The action of the drug is more energetic when ad-

ministered hypodermically, and a less dose by one-half is required than when given by the stomach.

The action of the alkaloid continues for from one to two hours, when it becomes completely exhausted, and the dose may be repeated; so that in the course of a day fifteen to twenty milligrammes may be given in three or four doses.

When administered to children, eserine produces its effect in a few minutes; more rapidly when injected subcutaneously than when given by the stomach.

Pallor is generally induced, the pulse becomes wiry; afterwards it is sometimes diminished in frequency.

Nearly all of the children treated by eserine showed symptoms of distress, with loud screaming, epigastric pain, gastralgia, nausea, and expectoration of a stringy fluid.

Sometimes the drug caused bilious vomiting.

No alteration of the temperature was observed.

Administered in the above doses, the alkaloid caused neither colic nor diarrhœa.

When given internally, eserine has no effect upon the pupil; the latter is neither dilated nor contracted.

Frequently considerable transpiration of the face and body is produced.

Paresis of the diaphragm, or its temporary paralysis even, is the most serious and painful of the symptoms produced after the subcutaneous injection of five milligrammes of the drug.

As soon as the alkaloid has exhausted its effect, the child recovers its normal condition, and the action of the drug does not appear to be followed by any after-effects.

When used in the above-mentioned doses, eserine does not appear in the urine.

When employed for the treatment of chorea, eserine arrests the movements during the continuance of its action, and little by little moderates them in the intervals, so that on an average the disease is cured in ten days.

The effect of the remedy is more certain when administered subcutaneously than when given by the stomach.

The writer has never seen tremulousness nor convulsions produced by the remedy, and thinks it probable that these accidents are only provoked by the drug in very large and toxic doses.—*Bulletin de Thérapeutique, Gazette Médicale de Paris*, June 12th, 1875.

REMARKABLE SLOWNESS OF THE PULSE, WITH FATTY DEGENERATION OF THE HEART.—Two cases of extreme slowness of the pulse were presented by Cornil and Malassez before the Société de Biologie, and are reported in the *Gazette Hebdom. de Méd. et de Chirur.*, of 11th June. In Cornil's case, the pulse was found to beat 24 times per minute at the first visit, while later it was only 14. Every quarter of an hour attacks of dyspnoea occurred, which terminated in syncope, which latter was associated with epileptiform movements. The attacks continued until death. At the autopsy complete fatty degeneration of the heart was found, but no valvular lesions. Malassez's case is described as presenting similar symptoms to those of the above. The pulse was 24 per minute. Sphygmographic tracings were presented in connection with the case.

A case of similar character is described by Dr. J. R. Leaming, in his paper on "Significance of Disturbed Action and Functional Murmurs of the Heart," which he lately read before the New York Academy of Medicine. In this case the pulse was 25 per minute, and complete intermissions occurred of from 13 to 16

seconds' duration. There were also epileptiform attacks, which occurred during the intermissions of the pulse as well as at other times. The attacks were afterwards relieved, and the patient died some two years later. At *post-mortem* examination the heart was found completely adherent to the pericardium; there was insufficiency of the aortic valves, and marked stenosis of the mitral; the heart was very much hypertrophied. No mention is made of fatty degeneration being found.

NYSTAGMUS AMONG MINERS.—Dr. Charles Bell Taylor, surgeon to the Nottingham and Midland Eye Infirmary, England, says that during the past few years he has noticed a peculiar malady among workers in collieries, and which he calls "miners' nystagmus," from the peculiar oscillating motions of the eyeball, which are characteristic of the disease, and from the fact that he has only observed it among adults, workers in the coal-pits, and independent of other ocular defects.

It was formerly supposed that nystagmus was incurable, always developed itself during infancy, and was caused either by imperfect nervous perception, or structural changes in the transparent media of the eyeball. In miners' nystagmus, however, the disease is developed in adults and aged persons previously healthy, is not accompanied by disease of the nerve or structural change of the eyeball, is usually curable, and is, as a rule, only to be noticed when the patient attempts fixation, especially in a stooping position. Dr. Taylor considers the affection analogous to writers' cramp, pianists' and telegraphists' cramp, or the similar affection of the gastrocnemii sometimes observed in ballet-dancers. It may be developed in any or all of the muscles supplied by the third nerve, and is clearly caused by the overtaxing of these organs.

The patient makes a great and sustained effort to see in an imperfect light; the muscles engaged in the accommodative strain are overburdened, in course of time give way, and at last, whenever called upon, just as in the analogous cases cited above, become, as it were, agitated and fluttered, escape from the control of the will, and perform irregular motions. Nystagmus generally persists so long as its cause remains, and, if developed in childhood, may continue even after its removal; but in "miner's nystagmus," as a rule, change of occupation and working in a good light are all that is necessary to effect a cure. Dr. Taylor says that it is worthy of note that the men are very apt to attribute their imperfect sight to one or other of the accidents which are so frequent among workmen underground. This is natural, of course, and acquires importance from a medico-legal point of view; but hitherto he has been unable to satisfy himself that in any case the accident had caused the affection, though readily inclined to grant that the nervous commotion and depressing influences of such injuries may aggravate an already existing disease, specially one so apt to be intensified by any nervous excitement.—*The Lancet*, June 12, 1875.

SCABIES CRUSTOSA.—Although it is not very uncommon for crusts to form in old cases of scabies, especially where they are protected from external violence, it is rare for them to form on the more exposed parts of the body. In this respect, as well as in the rapid growth and large size of the crusts, the inveterate cases described by Bergh in the *Hospitals Tidende*, 20-3, 1874, are of interest. In two cases the crusts were situated on the forearms and waist, and the animals, instead of spreading over the body, as they often do,

limited themselves to these particular parts. The author says it is not the itch-mites which, by their boring operations, produce the thickening of the skin, but the itching thus produced causes the patient to scratch and irritate the skin, which thus is inflamed and becomes thickened. The Norwegian animals spread in the crusts in colonies, and as one colony dies out its place is occupied by other colonies in succession.

A remarkable case is mentioned, where the patient, a man twenty-four years of age, had had the disease sixteen years, and with him the nails of the fingers and toes had become hypertrophied, and hooked like the claws of animals. According to the story of the patient, a hard mass was first formed under the nails of the fingers, and then of the toes. As these growths increased in size they gradually forced the nails out of position, and the latter then began to assume the claw-like form and size they presented when first seen by the doctor. Some years after the nails began to be affected the formation of crusts commenced in different places on the body. The growth of the nails was very rapid, and he was obliged to cut off as much as a quarter of an inch every two weeks. The cutting was somewhat painful, and occasionally excited bleeding from the matrix.

Under the microscope the crusts from the skin were found to consist of epidermoid cells, saturated with, and held together by, transuded matter and a molecular substance, mostly of a fatty nature, and mixed here and there with blood, which had given the crusts a yellowish color. Throughout their whole thickness they were filled with enormous quantities of excrement, egg-shells, eggs in all stages of development, the skins and other remains of the insects, and insects in various stages of development. Sections from the nails were also examined under the microscope, and found to consist of an axial portion of very well-preserved nail-substance, surrounded by a crust formation similar to that of the skin, though the passages and cavities in them were smaller, and the insect detritus was also much less in quantity. According to the author, the parasite which produces this disease is the ordinary itch-mite, the *sarcoptes hominis*, and differs from those commonly seen only in size.

At first the patient was treated with potash baths, and then a solution of carbolic acid, in the strength of 1 to 50, was applied to the entire surface. After the use of seven baths all the scabs had fallen off, and the nails, especially on the toes, had become smaller. A liniment of styrax was then used alternately with the above medication. The patient was under treatment for eighty days, but at length was regarded as entirely relieved from his trouble.

AN OPERATION FOR THE RADICAL CURE OF HERNIA.—Dr. Gussenbauer quotes from the *Memorabilien* this account of Dr. M. Langenbeck's mode of treating hernia. He had observed that the exudation following a subcutaneous restoration of a strangulated hernia was often sufficient to effect a firm closure of the hernial orifice, so that a truss was no longer needed. Accordingly he has adopted the following method, which he has put in practice in nine cases of hernia, as yet unstrangulated, with most favorable results. He forms from the skin of the thigh a tongue-shaped flap of $2\frac{1}{2}$ to 3 fingers' breadth at the base, and about two inches in length. This is then pushed without tension into the hernial canal, which has been freshened by the previous introduction of the index finger. The flap is secured in its place by sutures, the whole wound is filled with lint, and cold is applied for two or three days. At the end of this time the wound is

cleansed, and pressure applied by a sand-bag for a few days more. The patients were able to leave their beds at the end of ten days or a fortnight, wearing a truss until the skin was healed. Some patients treated in this way, when examined after three and six months, during which they had worn no truss, showed a firm closure of the canal, and there was no impulse communicated on coughing.—*Rundschau*, Feb. 28, 1875.

SYPHILIS AS A CAUSE OF PHTHISIS.—Whether phthisis is ever caused by syphilis has long been a disputed question among physicians. Dr. N. W. Thoresen has investigated the subject very thoroughly, and his memoir obtained the prize of the Medical Society of Christiania.

The history of three hundred and eighteen syphilitic parents is given, as well as that of all their children, up to the time of publication of his memoir.

It was often found that a syphilitic mother gave birth to a healthy child, which was nursed by her and which remained healthy, and if the mother were not treated the next child might have marked hereditary syphilis, or present other signs of ill health. In some cases several healthy children were successively born of such a mother, who then gave birth to syphilitic children. Others had syphilitic children, and then gave birth to perfectly healthy ones. In no case, however, could the origin of phthisis be traced to syphilis in the parents. It was invariably found that where the children had tubercles there was a history of this disease in their ancestors.

Of the whole number of syphilitic individuals examined, there were only sixteen who had tuberculosis, and there were none among these in which tuberculosis was not found to have existed as a family disease.

In the nine tuberculous individuals who became syphilitic, the course of the latter disease was very disastrous. The condition of those syphilitic individuals (twelve in number) who belonged to a tuberculous race, but who had not themselves had tubercles, was carefully followed, and though most of them had severe syphilitic accidents, none of them had any chest affections, and no other manifestations of tuberculosis were discovered.

The author concludes that syphilis has no causal relation whatever to tuberculosis, though the latter dyscrasia renders the prognosis of syphilis bad, just as any other depressing condition would.—*Norsk Med. f. Læg.*, April, 1875.

THE SPLEEN IN INFECTIOUS DISEASES.—In the *Berl. klin. Wochenschrift* for June 21, 1875, we find a notice of a pamphlet by Prof. Botkin, of St. Petersburg, on *The Contractility of the Spleen, and The Relation of Infection to the Spleen, Liver, Kidneys, and Heart*. These two essays were based upon clinical experience. As it was found from experiments performed on animals that irritation of the splenic nerves by electricity caused a contraction of the spleen, so our author, in cases of leukaemia, typhoid, epidemic gastro-enteritis, intermittent fever, and other diseases in the human subject, where the spleen was enlarged, has distinctly observed a sudden diminution of the size of that organ under the influence of electricity applied through the abdominal walls, of forced percussion, of palpation, and of mental emotions. Hence he infers the existence in the human subject of a central nervous apparatus, which, through the medium of the contractile elements of the vessels and the muscles of the proper substance of the spleen, influences the dimensions of the latter. In some cases of faradization of the spleen, simultaneously with its contraction, our author witnessed an increase in the size of the liver, evidently due to

the access of blood to it which had been driven out of the other organ; and again, in cases of leukaemia, after the size of the spleen had been reduced by faradization, the number of white corpuscles in the blood increased, indicating that the spleen had discharged a part of its contents. Botkin then finds the general condition of the patient improved by this treatment, and assumes that one of the two important functions of the spleen, viz., the conversion of white blood corpuscles into red, is arrested by those conditions, which, like its enlargement, interfere with the circulation of blood in it, and that, moreover, there is greater destruction of the red corpuscles from their longer retention. He therefore recommends faradization of the spleen as an important remedy, not only in leukaemia but in enlargements of it from other causes. He adds the history of three cases of leukaemia where this treatment was followed by a diminution of several centimetres in the size of the spleen, and improvement in the general condition of the patients. The enlarged lymphatic glands were also reduced in size.

Botkin alludes to the combination of various infectious diseases in the same individual, such as typhoid or typhus fever with relapsing fever, and also the influence exerted upon various local diseases by the prevalence or approach of an epidemic of an acute infectious character, especially such as affects the parenchymatous organs—the liver, kidneys, and spleen. He believes that persistent acute infectious diseases are a most fruitful source of chronic inflammations of the liver and kidneys, and of tumors of the spleen. Even when recovery seems to have been complete, he thinks we can often trace the connection of a cirrhosis of the liver, chronic Bright's disease, chronic enlargement of the spleen, and of leukaemia, to a former attack of cholera, typhoid or relapsing fever. Finally, he believes that a number of cases of fatty dilatation of the heart, without valvular disease, may be regarded as relics of former attacks of some infectious disease.

A CASE OF LYMPHORRHAGIA.—The following case is reported by Prof. Petters. For four years a woman of twenty-three had noticed a white, wart-like prominence on the left labium majus, which gave issue to a milky fluid, the flow persisting in spite of various remedies. This was soon complicated by swelling of the left labium and thigh. The patient married a year afterwards. During the ensuing pregnancy the discharge ceased, to recur again after convalescence from an abortion, which occurred at three months, and was followed by peritonitis. During its cessation the inguinal region and left thigh became more swollen. On admission the left thigh measured more than the right; the glands of the left groin were enlarged, and the labium of the same side presented a swelling as large as a pigeon's egg, studded with warty knots, which secreted a milky alkaline fluid, containing albuminate of soda, red blood corpuscles, numerous lymph corpuscles, and free fat, but no sugar and no urea. The quantity amounted sometimes to nearly six ounces in an hour and a half. The diagnosis of lymphorrhagia was confirmed by the post-mortem, the patient's death occurring rather suddenly with febrile symptoms and lymphangitis. There was found diffuse peritonitis, with purulent foci in the ovaries and tubes. The inguinal glands were much enlarged, and contained cavities filled with lymph. Around them were also found extensive spaces with smooth walls, likewise filled with lymph. The lymphatics of the left thigh were dilated, and the spleen enlarged.—*Prag. Fjurschr.*, cxxv. p. 69, 1875.—*Schmidt's Jahrb.*, 160, ii. June 17, 1875.

Correspondence.

HOSPITAL MANAGEMENT.

TO THE EDITOR OF THE MEDICAL RECORD.

STR:—In the discussion of any subject involving a principle, especially when the principle is not settled, there is always, I take it, room for suggestion. The leader on Hospital Management was one which was timely, and in the main I agree to the propositions laid down. The necessity for harmonious action on the part of the executive and the medical boards is, no doubt, the *sine qua non* of the prosperity of any hospital; but how this prosperity is best insured, how the harmonious understanding should be best preserved, is, to my mind, still a somewhat open question. Your recommendation that only the medical profession should be represented in the medical board, is well enough; but even this might lead to more or less trouble. There was such a representation in the board of managers of the Presbyterian Hospital; but, far from conserving the different interests of the institution, the opposite was the case. That same representative had a great deal to do with all the trouble with which the profession have lately become so familiar.

The difficulty was in the want of a proper understanding between the medical element of the managing board and the medical board proper, and this I imagine would be a chronic objection to the plan proposed in your recent editorial. It would hardly be possible for any medical board to bow submissively to the decision of one or two medical men, whose only right and fitness to decide ethical questions rested in the fact of their being members of the board of managers. There is, of course, no objection to having medical men members of the board of managers; but in that capacity they should not pretend to control the actions or construe the motives of their brethren of the staff. The medical staff should be able and competent to speak for itself, to plead its own cause, and to act in accordance with the dictates of its own judgment. In view of this, would it not be equally well to have the entire medical board a part of the board of managers, or at least be entitled to a seat in the board when any question bearing upon the interests of the hospital should come up? As they have only one interest in common—the good of the hospital—there would not be such a chance for quarrelling and such opportunities for misunderstandings as are witnessed under the present system.

I know there is a regulation in many hospitals providing for consultation on the part of the managers with the medical board; but, as you truly say, this is a rule more honored in its breach than its observance. The staff, on all such occasions, should consider it their right, and not a mere act of forced courtesy. The managers, it is true, should have the power to appoint these medical men; but when once appointed they should have all the privileges of attendance upon the board which belong to members of a society at stated meetings. The medical staff should hold office during good behavior, and should not be dropped unless for good cause, cause assigned in open meeting. Any member of the staff should run no more risk of being expelled or "voted out"—which is now the fashionable way of putting it—than he should be of expulsion from any medical society.

I fail to see how a fair and manly course by the managers, when any charge is brought against a medical man, should be productive of anything but benefit to all parties concerned. There would at least be a good opportunity offered for a free discussion of the merits of any given case, and any member of the medical board would not then be left out in the cold without due notice. It is a small matter, perhaps, to vote a man out, but the victim is hardly prepared to be satisfied with the verdict, unless he has an opportunity of putting in a defence in the trial. I do not see how any reasonable objection should be made against such a proceeding.

The trouble with the Presbyterian Hospital had its principal cause in the mismanagement of a party who was trusted with the functions of executive officer of this hospital. As very often happens, a spirit of domineering began to show itself, which was resented by the majority of the medical staff. In the main this interference scarcely amounted to more than petty annoyances; but the continual dropping wore away patience, and a rupture was the result. The questions in dispute were more or less of a purely medical character, but the judgment of members of the medical staff amounted to nothing in comparison with the fiat of the executive officer. I do not think it is necessary to make explicit charges; it is sufficient to know the facts of the case, which can be substantiated by members of the medical board. Complaints were made of the obnoxious person to the board of managers, but failed to have the desired effect of changing the method of management, and there the matter rested until it became a question whether it were better to get clear of the defendant or the plaintiffs. Everybody knows the result. Medical men could be obtained so much easier to fill vacant places than executive officers, that the easiest way to get out of a difficulty was to "vote out" the obnoxious ones. The wisdom of this course of action is seen by the prompt manner in which the vacant places on the staff were filled. Now, I contend, if the medical board were allowed a membership of the board of managers, this difficulty would not have occurred. There would have been a candid and impartial examination of the point at issue, and there would have been no occasion for the disgraceful wire-pulling which has made the Presbyterian Hospital affair a byword of reproach for the profession of the country.

AN OUTSIDER.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from August 15th, 1875, to August 21st, 1875.

COOPER, GEO. E., Surgeon.—Leave of absence extended fifteen days. S. O. 166, A. G. O., August 18, 1875.

STERNBERG, GEO. M., Assistant Surgeon.—Granted leave of absence for one month on surgeon's certificate of disability. S. O. 151, Depart. of the Gulf, August 14, 1875.

FORWOOD, WM. II., Assistant Surgeon.—Leave of absence extended two months. S. O. 46, Hdqrs. of the Army, Aug. 12, 1875.

NEWLANDS, W. L., Assistant Surgeon.—Assigned to duty at Camp Halleck, Nev. S. O. 87, Depart. of California, Aug. 6, 1875.

NAVY NEWS.

August 13th.

AMBLER, J. M., Assistant Surgeon.—Ordered to the *Minnesota*.

MARTIN, EDWIN M., Assistant Surgeon.—Detached from the Navy Yard, and ordered to the *Intrepid*.

McMURTRIE, D., Surgeon.—Has reported his return home from the Navy Yard, at New York, and ordered to the *Intrepid*.

August 17th.

SMITH, HOWARD, Assistant Surgeon.—Is ordered to the Naval Hospital, New York.

MARINE HOSPITAL SERVICE.

SMITH, ORSAMUS, Surgeon.—Transferred from Louisville, Ky., to Mobile, Ala., August 4. Surgeon Smith is directed to open the Marine Hospital at that port as a Government Hospital, Class I.

MUILENBERG, HENRY E., JR., Assistant Surgeon.—Relieved from temporary duty at Chelsea, Mass., and assigned to Philadelphia, Pa.

ROBINSON, SAMUEL Q., Assistant Surgeon.—(Passed the Board of Medical Examiners July 20-25.) Appointed Assistant Surgeon, July 29, and assigned to duty at Chelsea, Mass., July 31.

DOERING, EDWARD J., Assistant Surgeon.—(Passed the Board of Medical Examiners July 20-25.) Appointed Assistant Surgeon, July 29, and assigned to duty at San Francisco, Cal., July 31.

CHIPMAN, W. R., Hospital Intern.—Appointed and assigned to duty at Chelsea, Mass., July 30.

Medical Items and News.

"MEDICUS" will secure the publication of his letter if he will send us his name as a guarantee of good faith. No communications to THE RECORD should be anonymous to the editor.

PRIZE OF THE GENEVA CONVENTION.—The prize of 2,000 thalers, for the best work in the Geneva Convention, has been awarded to Professor Läder, of Erlangen.

CHOLERA IN SYRIA.—The *Fakit*, a Turkish newspaper, published at Constantinople, states that the cholera in Syria is considerably increasing. According to it, during the past week, the number of cases reached 500, a great part of which were fatal.

THE AMERICAN ACADEMY OF DENTAL SCIENCE will hold its eighth annual meeting in Boston, on Monday, September 27th, at 10 A.M. The annual address will be delivered by Dr. Robert Arthur, of Baltimore.

THE FECUNDITY RELATIVE TO MARRIAGES IN EUROPE.—The average number of children by marriage varies from 4.73 to 3.07. Russia stands at the head with the number 4.73; France last with 3.07. The ratio of fecundity is as follows: Russia, Spain, Scotland, Ireland, Italy, Hungary, Norway, Sweden, Wurtemberg, Prussia, Holland, Austria, Belgium, England, Saxony, Denmark, Bavaria, France.

The reason for the small increase in the French population cannot be found either in the period of marriages nor in their number, nor in the mortality of infants or adults; but it is solely from the limited (and voluntary) fecundity of marriages.

UNVEILING OF PROF. HYRTL'S BUST.—By a resolution of the College of Physicians of Vienna, the bust of Prof. Hyrtl, the anatomist, has been placed in the principal hall of the university.

The ceremony of unveiling took place on the 22d of June, at which Hyrtl was present.

DEATH OF MR. JOHN CHURCHILL.—This eminent medical publisher, who for many years has been most intimately associated with the members of the medical profession by the publication of their works, died at Tunbridge Wells, on the 3d instant, within a few weeks of completing his seventy-fourth year.

DIMINUTION OF DOCTORS IN FRANCE.—M. Paul Bert has stated in the National Assembly, that the total number of practitioners has diminished in France from 17,192, in 1866, to 15,429, in 1872. It is said that the religious sisterhoods have by their numbers and their habit of practising among the middle and lower classes, almost unrestrained, become formidable opponents of educated physicians, and together with the low rate of compensation and high price of living, deter men from entering the profession.

BLUE URINE.—In a case recently described to the Société de Biologie by M. A. Robin, a curious blue tint of urine corresponded to attacks of lumbar pain. The urine was scanty, not actually blue when passed, but on standing a sediment fell in which were many deep-blue granules, distinct under the microscope, showing no trace of crystallization. The nuclei of cells of bladder epithelium were also stained blue. Urea and uric acid were lessened in amount. The blue substance was a little soluble in water, hardly soluble in alcohol or ether, insoluble in chloroform or alkalies, soluble in sulphuric acid, with a tint at first rose, then reddish-orange; soluble in hydrochloric acid, with a magnificent carmine color. It corresponds closely with the cyano-urine of Braconnet, who believed it to be a transformation of uric acid less oxidized than urea.

THE PRACTITIONER has issued to its subscribers the first of a series of questions relating to the treatment of some diseases, with the intention of tabulating them and publishing the results. In the present instance the disease in question is quinsy, and the questions are as follow: What are the drugs you generally prescribe in this disease? What preparations of these drugs, and what doses do you generally prescribe? What local treatment do you employ? What diet and regimen? How is your choice of drugs and line of treatment modified by the following circumstances:—(a) Constitution of patient (strumous, rheumatic, gouty, etc.). (b) Age and sex. (c) Symptoms—(1.) Pain in throat; (2.) swelling in throat; (3.) pains in limbs; (4.) constipation? To what extent do you resort to surgical influence? The blank form has a postage stamp affixed, and is addressed to The Editor of *The Practitioner*, 23 Somerset Street, Portman Square, London, W.

MEDICAL SCHOOLS IN FRANCE.—The French Government have adopted a law which permits the founding of medical schools by private enterprise. It is expected that the competition between the new schools, thus organized, and the old and privileged bodies will result in great improvement in the methods of teaching. The law does not grant those schools licensing powers, and the examination for the granting of the degree is still, as before, under the control of the government. Schools have been organized in Nancy and Lyons, under the provisions of the recent law, and extensive preparations have been made for the course, which is to open in November.

Original Lectures.

COMMON SENSE IN THE SICK-ROOM.

A LECTURE DELIVERED AT THE BELLEVUE HOSPITAL
MEDICAL COLLEGE,

By A. B. CROSBY, M.D.,

PROF. OF ANATOMY, ETC.

GENTLEMEN:—I now ask your attention to what may be called "*common sense* in the sick-room." There are certain incidental matters pertaining to the sick-room which not only contribute to the comfort of the patient, but have very much to do with the favorable or unfavorable termination of the case, and these elements are so absolutely suggested by common sense, that there is no impropriety in using this term as a text for the present lecture.

Now there are certain elements of hygiene which it is very important that we should observe—whether the sick-room contains a surgical or medical case—if we would reasonably expect to obtain the best possible results from treatment. In the first place the

TEMPERATURE

should ordinarily range from 65° to 70° F., and this should not be a mere matter of guess-work, but should be ascertained by the thermometer. If the temperature is permitted to average much higher than this, all febrile disturbances will very likely be aggravated; and if the average is much lower, the patient in ordinary cases runs some risk of getting a chill, although, very many times he may remain with safety in a room having a lower temperature, providing he is furnished with a plentiful supply of blankets.

SELECTION, PREPARATION, AND FURNITURE OF THE ROOM.

The room which is selected for a sick-room should be as far removed as possible from those ordinarily occupied by the family, in order that the patient may have the benefit of perfect quiet. It should be large, airy, well lighted, and, if possible, should have a sunny exposure.

The *wall* of the sick-room is a pretty important matter to the patient. If it is covered with one of those dreadfully variegated papers, which, alas; are regarded as ornamental, it will be found, especially if the patient is suffering from any disease in which there is abnormal exaltation of the brain, that it is a source of great annoyance, and may even be positively injurious. For, as his eyes run over these pictures, he will fancy that he sees images of various kinds, such as angels and demons alternating; indeed these figures will assume every conceivable form, and he becomes thoroughly worried in the attempt to disentangle the confusion.

The paper covering the wall should have a uniform, neutral tint, such as a light green, a delicate buff or a very delicate slate color, a light green, perhaps, is as agreeable to the eyes as any color that can be selected, and it rests the eyes with a refreshing monotony. Such a uniform tint tends to "healthy stupidity," and this leads to repose. The *floor* of the apartment should engage your attention.

The model sick-room should never be carpeted, but ordinarily should have a hard-wood floor, and this should be oiled and varnished. Upon such a floor

may be spread as many pieces of carpeting, rugs, and mats as are desirable. These may be placed in front of the bed, over the parts which the nurse traverses while performing his or her duties, at the doors, etc. Each morning, these can be quietly slid along the floor, taken out, and be thoroughly shaken and aired. After they are removed, the floor can be wiped off with a damp cloth or soft brush, and when dry, the rugs, etc., may be replaced.

If the floor is managed in this manner, what was known among the older writers as the *materies morbi*, certainly is not likely to accumulate, and that is an essential item of consideration in the management of the sick-room. The *windows* should also engage your attention. These should be so arranged as to admit abundance of light. Light is a nominal stimulus to the human body, and we have no good health without it; you cannot grow healthy cabbages in a dark cellar, nor can you any more easily cure invalids without the influence of sunlight. There are some acute diseases, during the progress of which it may be necessary to temper the light, but it should never be entirely shut out, for if you do you remove from the body one of its important natural stimuli.

The windows never should be surrounded by tapestry or decorations of any kind that are made of woolen stuff. A plain white shade is all that is requisite to temper the light and cut off outside objects from the patient's view, and the window-frame should be free from lambrequins, hangings, etc., which may become impregnated with the germs of disease.

CLEANLINESS.

It may seem absurd to you that I mention cleanliness as an essential element in a sick-room, and insist that it is one of the things which you should bring under your personal inspection, but I suspect that it is far less frequently seen in the sick-room than even godliness itself, although we have eminent authority for placing it *next* to godliness.

The average housekeeper is very apt to make a good show, hence covers the bed with a clean counterpane, which may be like a "whited sepulchre," within are "deadmen's bones;" and it is true, in very many instances that absolute cleanliness will not be maintained unless the physician himself makes an inspection of the details. Your patient may live in a fine house, belong to an "old family," one regarded as irreprouchable in respect to cleanliness, and yet a sanitary inspector may find many hygienic errors to be corrected. Now, if the floor is not covered with a carpet, the physician can very easily determine whether it is clean or not; but if carpeted, it is altogether probable that a considerable amount of dirt could be found if the carpet were removed. Next you will observe what condition the bed itself is in. I am well aware that it is an easy matter to place a neat, clean sham over the pillow, and a clean spread over the ordinary covering, just before the doctor is admitted, so that the bed may have the distinguished appearance of cleanliness; but it is not a difficult matter to turn these aside sufficient to enable you to determine for yourselves whether the real covering of the bed and pillows are clean or not, and your examination can be conducted delicately without giving offence or even being observed. In a majority of cases, changing the bed-linen once or twice a week is not sufficient. When a person is confined to the bed, especially with any febrile disorder, at least one clean sheet should be placed upon the bed each day.

This may be the upper one, and it may be used as

an under sheet the following day, if it has not become soiled. The pillow-cases should be changed equally as often. If the patient is suffering from any of the severer forms of acute febrile disease, such as scarlatina, typhoid fever, etc., or from a disease in which there is any tendency to septic influences, an immense benefit will be derived from changing the bed through-out every day.

IMPROVISED STRETCHER.

Suppose, now, that your patient has received some severe injury, or is suffering from some disease which renders it desirable that his bed should be changed daily, or even oftener, how can it be done with the least inconvenience to him? If there are two beds in the room, one may be rolled close alongside the other, and then the patient be lifted from one to the other; and it is a good plan to allow him to occupy one bed at night and the other during the daytime. This is especially beneficial when there is any tendency to septic disease, or the patient is severely sick with some febrile disorder, for it gives the attendants an opportunity to remove all the bedding into another room or other convenient place, where it may be shaken and thoroughly aired so that when it is again used it will be entirely refreshed. All this can be done without annoying the patient, even though he is extremely sick or suffering from a severe injury.

But it may be said that moving a patient so much, who is extremely sick, is of itself objectionable. This, however, is not a valid objection, for the reason that it can be done without inconvenience to any patient. If there is a condition present known as hyperinosis, such as is frequently seen in puerperal women, there may be an objection to moving the patient in an upright posture, or even permitting her to assume such a posture, lest embolism or thrombosis occur suddenly and terminate life; but such a person can be moved with perfect safety while kept in the horizontal posture, and even carried from one room to another if desirable.

Place the means for moving such patients from one place to another can be found about any house, especially in the country, and I have succeeded in obtaining all the materials necessary for this purpose even in a medical college. What I wish to do is to improvise a *stretcher*, and for that purpose all that is necessary is a strong sheet or blanket as long as the patient, two rods of the same length of the sheet and an inch or more in diameter. If you are in the country you certainly can find rake-handles, and they answer the purpose as well as anything that can be used. In order to move a person easily, four assistants are necessary, who are to stand, two on each side of the sheet and *exactly* opposite each other.

Let us suppose, now, that the sheet upon which this gentleman is lying is the one to be made into a stretcher; you will place one of the poles close to the edge of it, and then roll the sheet over it very tightly up to perhaps within six or eight inches of the body. It does not require strong rods at all for this purpose, but the special point is to draw the sheet out smoothly from the patient while you are rolling the stick up inside of it. The opposite rod is adjusted in the same manner. When every thing is ready the assistants should grasp the rod firmly with their hands placed about two feet apart, and, as near as possible, directly opposite each other, so that as they lift, and at the same time draw against each other, the sheet will be supported at exactly opposite points. Now direct the assistants to first drag strongly against each other and then lift, and keep constantly pulling against each other as they move along. Such a stretcher can be

easily improvised, and affords a means by which a patient can be moved without annoyance. If the patient whom you are moving happens to have a fracture, unless the precaution is exercised of directing one assistant to grasp the rod with his hands exactly opposite those of the assistant upon the opposite side, you may disturb the broken bones in the act of moving.

If you wish to move a man who has accidentally received an injury, any distance, a stretcher can be improvised in a similar manner, by using a blanket and a couple of poles, such as a couple of strong sapplings would make, fastening them in the blanket with stitches of twine or strong thread, and then placing a forked stick between the handles close up to the blanket, of such length as will put it upon the stretch. If the number of bearers is limited to two, and they desire to assist their arms, it can be done by fastening a strap to the handles long enough to pass up over the shoulders.

There is one precaution that the bearers should always exercise, and that is, to break steps while walking. If the bearer in front steps off with the right foot, the bearer behind should advance the left foot first.

All of this may appear to you like an insignificant matter, but it not infrequently happens that the comfort of your patient, the rapidity of his recovery, and, it may be, the recovery itself, will materially depend upon your ability to devise a plan for moving him from one bed to another without annoyance, and while in the horizontal posture. In ordinary cases of sickness, one bed can be brought to the side of another and the patient slid from one to the other, or he may be lifted across in the sheet; but where persons are very much debilitated or suffering from a severe injury, they may not be able to endure the fatigue which even such slight movements will subject them to. In such cases the means just described may be resorted to with the greatest advantage.

MANAGEMENT OF THE DEJECTIONS.
